Before you start, see What Are Cloud Identity Services? [page 7]

What's New

Stay informed about the newest features and updates of SAP Cloud Identity Services.

For more information, see What's New for Cloud Identity Services [page 26].

Concepts

Understand the concepts relevant for SAP Cloud Identity Services.

For more information, see Concepts [page 26].

Initial Setup

Explore the required steps to get started with SAP Cloud Identity Services.

For more information, see Initial Setup [page 523].

Scenarios

Understand the scenarios supported by SAP Cloud Identity Services.

For more information, see Scenarios [page 544].

Systems

Familiarize yourself with the supported provisioning systems (connectors) by Identity Provisioning.

For more information, see Supported Systems [page 585].

Administration

Learn how to configure and administer SAP Cloud Identity Services.

For more information, see Administration [page 1918].

Security

Use the security features of SAP Cloud Identity Services to support the security policies of your organization.

For more information, see Security [page 2896].

Monitoring

Explore monitoring and reporting to get information about audit logs, job logs, usage statistics, and more.

For more information, see Monitoring and Troubleshooting [page 2964].

APIs

Get to know the APIs of SAP Cloud Identity Services delivered on the SAP Business Accelerator Hub.

For more information, see SAP Cloud Identity Services APIs.

Support

Get support when you have questions or encounter issues while working with SAP Cloud Identity Services.

For more information, see Getting Support [page 3141].

1.1 What Are Cloud Identity Services?

Manage identities, authorizations and SSO across cloud and on-premise solutions.

SAP Cloud Identity Services are a group of services of SAP Business Technology Platform (SAP BTP), which enable you to integrate identity and access management between systems. The goal is to provide a seamless single sign-on experience across systems while ensuring that system and data access are secure. SAP Cloud Identity Services include Identity Authentication, Identity Provisioning, Identity Directory, and Authorization Management.

Environment

SAP Cloud Identity Services run on several underlying Infrastructure-as-a-Service technologies and regions. Regions are provided either by SAP or by SAP's Infrastructure-as-a-Service (IaaS) partners Amazon Web Services (AWS), Microsoft Azure, Google Cloud, and Alibaba Cloud. The third-party region providers operate the infrastructure layer of the regions, whereas SAP operates the platform layer. For more information, see Regional Availability [page 11].

SAP Cloud Identity Services are available for consumption with the following SAP BTP environments:

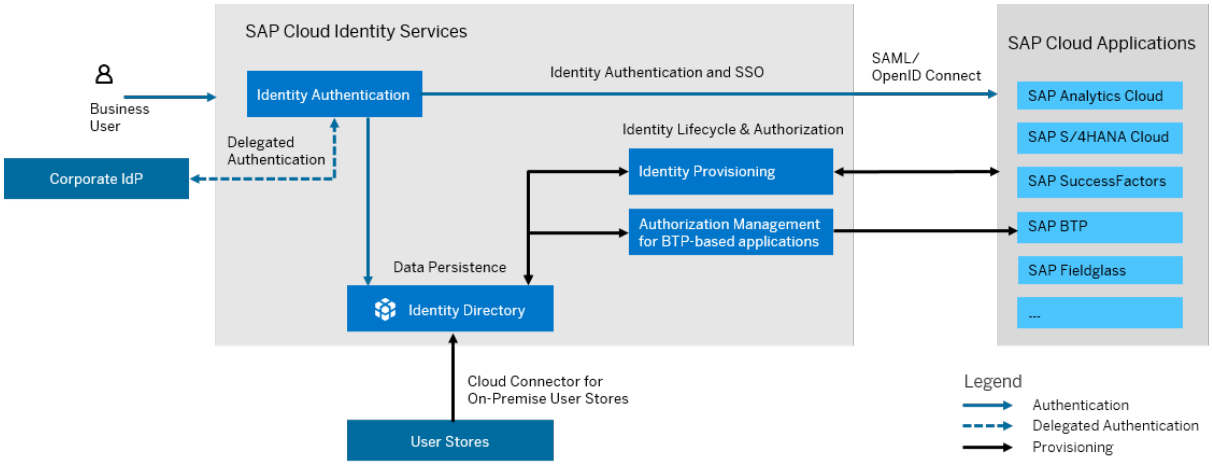
- Cloud Foundry
- Kyma
- Neo

Features

Authentication and SSO	Choose one of the supported authentication methods to control access to your application, like Form, SPNEGO, Social, or 2FA. Use OpenID Connect or SAML 2.0 to provide single sign-on. Integrate your application programmatically using authentication via API.

Data Persistence	Store and manage users and groups in Identity Directory - the user store of SAP Cloud Identity Services.
Delegate Authentication	Delegate authentication to a 3rd party or on-premise IdP, as default or based on a condition like IdP, email domain, user type or user group, and thus enable SSO across on-premise and the cloud.
Job Logging and Notifications	View and manage job logs and real-time provisioning logs. Subscribe to source systems and receive notifications for the status of provisioning jobs.
Policy-Based Authorizations	Develop SAP BTP applications with instance-based authorizations. Configure those instance-based authorizations centrally as policies within SAP Cloud Identity Services.
Risk-Based Authentication	Help enforce two-factor authentication based on IP ranges, user groups, user type, or authentication method to manage access to a business application.
User and Group Management via API	Use SCIM REST API to manage users and groups, invite users, customize end-user UI texts in any language.
User and Group Provisioning	Synchronize users and groups between multiple supported cloud and on-premise systems, both SAP and non-SAP. Filter data. Run jobs in full and delta read mode.

Overview Graphic



Identity Authentication

Identity Authentication provides you with controlled cloud-based access to business processes, applications, and data. It simplifies your user experience through authentication mechanisms, single sign-on, on-premise integration, and convenient self-service options. Identity Authentication provides the following benefits:

- Authentication: All SAP cloud applications can offer their users the same authentication mechanisms , as well as strong authentication with configurable multi-factor (MFA) enforcement; easy separation mechanism for multiple user stores and flexible configuration where to validate user's credentials.

- Single Sign-On: Identity Authentication offers central SSO endpoint for all SAP cloud applications and pre-configured or semi-automated trust configuration.
- Integrating SAP applications: Identity Authentication offers common identity for users, as well as a unified way for user management and security token service for protection of system-to-system communication. Data across applications can be correlated (precondition for central foundation services).

Identity Provisioning

Identity Provisioning offers easier and more secure identity lifecycle management as a service with identity and authorization provisioning and deprovisioning. It enables customers to set up faster and more efficient administration of user onboarding and offboarding. Identity Provisioning supports a centralized lifecycle of corporate identities in the cloud. In addition, it can handle automated provisioning of existing on-premise identities to cloud applications.

Identity Directory

Identity Directory is the persistency layer of SAP Cloud Identity Services. It offers a central place for storing and managing users and groups. Its SCIM 2.0 REST API allows customers to define their own custom schemas with own attributes. The directory generates the Global User ID attribute - the unique user identifier across landscape. This attribute is distributed by Identity Provisioning to SAP cloud applications, like SAP Task Center, which need the common user identifier in their integration scenarios.

Authorization Management

Authorization Management enables you to refine authorization policies that give access to resources in enabled SAP BTP-based business applications. Restrict policies based on the values of user or business object attributes. Assign policies to users with the group management capabilities of the identity directory. Use the corresponding user interfaces of SAP Cloud Identity Services or the SCIM API of the identity directory.

Use Cases

SAP Cloud Identity Services offers the following scenarios:

- Identity Authentication Scenarios [page 544] for consumers (business-to-consumer scenarios), partners (business-to-business scenarios), and employees (business-to-employee scenarios).
- Authorization Management Scenario for configuring and assigning authorization policies to users.
- Identity Directory Scenario for storing and provisioning users and groups.
- Identity Provisioning Scenario for using bundled tenants in provisioning and deprovisioning.

Prerequisites

To use SAP Cloud Identity Services, you must obtain a tenant. It's delivered to you as part of a bundle with an SAP cloud solution or as part of a self-service request in SAP BTP cockpit.

For more information, see Tenants [page 27] and Bundles [page 35].

Tools

The central point of entry to SAP Cloud Identity Services is the administration console, where you can manage tenant configurations, user authentication and provisioning. It is a Fiori-based user interface adaptive to most browsers.

For more information, see Operation Guide.

Regional Availability [page 11]
: Tenants are deployed on the productive domains `accounts.ondemand.com` and `accounts.cloud.sap`.

Disaster Recovery/High Availability [page 21]
: Disaster recovery (DR) and high availability (HA) are based on the capabilities of the underlying infrastructure.

Web-Based Logon Interface [page 22]
: Service providers that delegate authentication to Identity Authentication can use two types of visualization of the web-based user interfaces for the logon pages of their applications.

Browser Support [page 23]
: Information on the supported browser version for the administration console, and the end user screens of SAP Cloud Identity Services.

Supported Languages [page 24]
: Information on the supported languages for the administration console, and the end user screens of Identity Authentication.

Accessibility Features in SAP Cloud Identity Services [page 25]
: To optimize your experience of SAP Cloud Identity Services, SAP Cloud Identity Services tools provide features and settings that help you use the software efficiently.

1.1.1 Regional Availability

Tenants are deployed on the productive domains `accounts.ondemand.com` and `accounts.cloud.sap`.

The productive domain is available on a country/regional basis, where each country/region represents the locations of data centers. The productive domain represents the productive environment. It can be used by customer and partner accounts only.

A customer or partner account is associated with a particular data center and this is independent of your own location. For example, you could be located in North America, but operate your account in Europe. Thus, you use a data center that is situated in Europe.

Country/regions with more than one data centers operate in high availability (HA) mode among the respective data centers. Tenants located in these country/regions are distributed among the data centers there.

The country/region, domain, data center, and IP address are listed below:

Productive Environment

Country/ Region	Domain	Data Center	Infrastructure	LB IPs	NAT IPs	First IP - Last IP
Australia	`accounts.ondemand.com` `accounts.cloud.sap`	Australia (Sydney)	SAP / Azure	**157.133.168.73, 4.200.99.225**	**157.133.168.32/27, 130.214.240.32/27, 13.70.93.153/32**	**157.133.168.32-157.133.168.63, 130.214.240.32-130.214.240.63, 13.70.93.153-13.70.93.153**

Supported Languages [page 24]
Accessibility Features in SAP Cloud Identity Services [page 25]

1.1.1.1 Updating Host URLs for Shanghai Tenants

If your Identity Authentication tenant host is in the Asia-Pacific region, precisely Shanghai (China), you must update it to the new host: `accounts.sapcloud.cn`.

Context

The former domain on which you've accessed your Shanghai (China) tenants is: `accounts.ondemand.com`. This domain will soon stop working, thus we recommend that you start using the new one. Effective September 2020, tenants from Shanghai (China) should be accessed via the following domain: `accounts.sapcloud.cn`.

> **Note**
>
> The other productive domains, available on a country/regional basis, are working as usual.

The migration procedure for Identity Authentication tenants affects the following scenarios:

- SAML 2.0 Application Configuration
- OpenID Connect Application Configuration
- Real-Time User Provisioning
- Delegated Authentication
- API Usage
- IdP-Initated SSO

For more information about the migration procedure for SAP Cloud Identity Services - Identity Provisioning, see Updating Host URLs for Shanghai Tenants.

SAML 2.0 Application Configuration

Context

When you set the trust between Identity Authentication, acting as identity provider (IdP), and the service provider, make sure that you use the Identity Authentication metadata downloaded via the new host `https://<tenant Id>.accounts.sapcloud.cn/admin`.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services via the new URL `https://<tenant Id>.accounts.sapcloud.cn/admin`.
2. Access *Applications and Resources* > *Tenant Settings* > *SAML 2.0 Configuration*.
3. Download the new SAML metadata of Identity Authentication.

   > **Note**
   >
   > If you do not have access to the trust configuration on the application side report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

4. Configure the new metadata of the Identity Provider (IdP) on the application (service provider) side. See Tenant SAML 2.0 Configurations [page 2103].

   If you have set trusts with more than one service provider, configure the metadata in every service provider. For more information about how to configure the metadata, see the documentation of the respective service providers.

OpenID Connect Application Configuration

Context

If your application an OpenID Connect one, update the configurations in the administration console for SAP Cloud Identity Services to match the new host.

Procedure

1. In the administration console for SAP Cloud Identity Services, access *Applications and Resources* > *Tenant Settings* > *OpenID Connect Configuration*.
2. Update the name of the identity provider to match the new host name (https:// <tenant ID>.accounts.sapcloud.cn).
3. Update the endpoints on the relying party (RP) side to match the new host.

Real Time User Provisioning

Context

When you want to perform real-time provisioning through the administration console for SAP Cloud Identity Services, make sure you use the correct domain when you construct your OAuth URL and SCIM URL.

Procedure

1. Access theIdentity Authentication tenant via the new domain `<tenant Id>.accounts.sapcloud.cn`.
2. In the administration console, access *User Provisioning*.
3. Update the *host* part in the *SCIM URL* and *OAuth URL* of the Identity Provisioning target system with the new domain `dispatcher.cn1.platform.sapcloud.cn`. See Real-Time Provisioning: Identity Authentication

   SCIM URL Pattern: `https://ipsproxy<provider_account>-<consumer_subaccount>.<host>/ipsproxy/api/v1/systems/<Identity_Authentication_ID>/entities/user`

   OAuth URL Pattern: `https://oauthasservices-<consumer_subaccount>.<host>/oauth2/api/v1/token`

Delegated Authentication

Context

In this scenario Identity Authentication acts as a proxy to the corporate identity provider.

When you set the trust between Identity Authentication, acting as a proxy), and the corporate IdP, make sure that you use the Identity Authentication metadata downloaded via the new host `https://<tenant Id>.accounts.sapcloud.cn/admin`.

For more information about the scenario, Corporate Identity Providers [page 2556].

Procedure

1. Access theIdentity Authentication tenant via the new domain `<tenant Id>.accounts.sapcloud.cn/admin`.
2. In the administration console, access *Applications and Resources* > *Tenant Settings* > *SAML 2.0 Configuration* .
3. Download the new SAML metadata of the identity provider (IdP).

   > **Note**
   >
   > If you don't have access to the trust configuration on the application side report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

4. Update the trust configuration on the corporate identity provider side.

API Usage

Procedure

Use the new domain in the URLs. See API Documentation [page 2790].

URL: https://<tenant ID>.accounts.sapcloud.cn/<...>

Identity Authentication IdP-Initated SSO

Procedure

Inform the end users about the new IdP-initiated links, updated with the new domain.

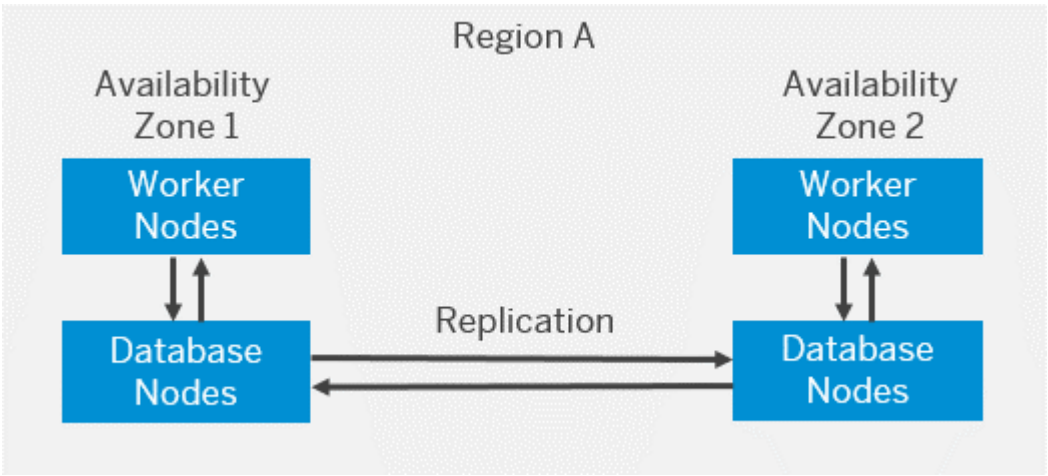
1.1.2 Disaster Recovery/High Availability

Disaster recovery (DR) and high availability (HA) are based on the capabilities of the underlying infrastructure.

Identity Authentication is a multi-tenant system where tenants share the hardware and software and use dedicated (and isolated) database instances for persistence.

High Availability - Single Region Setup

All deployments that have one data center support replication of the data between two zones within the same region.



Backup and Recovery

A full backup is performed everyday at 01:00 UTC. The backup is kept for 90 days.

If a restore is required due to an issue on infrastructure level, then SAP DevOps team takes care of the recovery procedure.

If a restore is required due to an issue on application level, report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

Accessibility Features in SAP Cloud Identity Services [page 25]
Cloud Service Status

1.1.3 Web-Based Logon Interface

Service providers that delegate authentication to Identity Authentication can use two types of visualization of the web-based user interfaces for the logon pages of their applications.

The two types of visualization of the web-based user interfaces are on a fullscreen of the window and with overlay on top of the application page.

Overlay

The use of overlays maintains the application context, by keeping the application page as dimmed background, to provide for minimum disturbance to the work flow. The logon page is open in an iframe over the public page of the application.

Fullscreen

The logon page is displayed on fullscreen in the browser when at least one of the following conditions is fulfilled:

- the overlay is not integrated in the application

- the application does not provide a public page
- the user opens directly a protected page of the application

Supported Browser Versions for Administration Console

The Administration Console uses the SAPUI5 libraries. For more information on the supported browsers, see Browser and Platform Support.

Supported Browser Versions for End User Screens

Supported Desktop Browsers

The end user screens, such as logon, forgot password, and so on, of the applications that use Cloud Identity Services for authentication, support the following browsers:

Web Browser	Supported Version
Microsoft Edge	Latest Version
Mozilla Firefox	Latest Version
Google Chrome	Latest Version
Safari	Latest Version

> **Note**
>
> You cannot use versions 7 and 8 of Microsoft Internet Explorer for some user interfaces (responsive user interfaces).

Supported Mobile Browsers

Web Browser	Supported Version
Mobile or iOS Safari	Latest Version
Android Browser	Latest Version
Google Chrome for Android	Latest Version
Internet Explorer Mobile	11 or higher
Blackberry Browser	10.0 or higher

1.1.5 Supported Languages

Information on the supported languages for the administration console, and the end user screens of Identity Authentication.

Supported Languages for Administration Console

The administration console for SAP Cloud Identity Services supports only English (en) language.

Supported Languages for Identity Authentication End User Screens

The end user screens of the applications that use Cloud Identity Services for authentication, support the following languages: Arabic (ar), Bulgarian (bg), Catalan (ca), Chinese PRC (zh_CN), Chinese Taiwan (zh_TW), Croatian (hr), Czech (cs), Danish (da), Dutch (nl), English United Kingdom (en_GB), English United States (en_US), Estonian (et), Finnish (fi), French Standard (fr), French Canada (fr_CA), German Standard (de), Greek (el), Hebrew (iw), Hungarian (hu), Italian (it), Japanese (ja), Korean (ko), Latvian (lv), Lithuanian (lt), Malay (s), Norwegian (no), Polish (pl), Portuguese Portugal (pt), Romanian (ro), Russian (ru), Serbian (sr), Slovak (sk), Slovenian (sl), Spanish Standard (es), Spanish Mexico (es_MX), Swedish (sv), Thai (th), Turkish (tr), Ukrainian (uk), Vietnamese (vi), Welsh (cy).

1.1.6 Accessibility Features in SAP Cloud Identity Services

To optimize your experience of SAP Cloud Identity Services, SAP Cloud Identity Services tools provide features and settings that help you use the software efficiently.

> **Note**
>
> SAP Cloud Identity Services is based on SAPUI5. For this reason, accessibility features for SAPUI5 also apply. See the accessibility documentation for SAPUI5 on SAP Help Portal at Accessibility for End Users.

For more information on screen reader support and keyboard shortcuts, see Keyboard Handling for SAPUI5 UI Elements and Screen-Reader Support for SAPUI5 Controls.

1.2 What's New for Cloud Identity Services

See the latest release notes for SAP Cloud Identity Services. It contains updates about new features and enhancements.

What's New Viewer

1.3 Concepts

This section describes basic concepts that will help you familiarize yourself with the SAP Cloud Identity Services.

Tenants [page 27]
: A tenant refers to your (customer-specific) instance of SAP Cloud Identity Services. It's delivered to you as part of a bundle with an SAP cloud solution or as part of a self-service request in SAP BTP cockpit.

Bundles [page 35]
: A bundle is a group of preconfigured products and services which are sold together.

Applications [page 61]
: An application is associated with a consumer of Identity Authentication as an identity provider. This consumer could be for example an SAP cloud solution, a third-party application, SAP BTP subaccount, or the SAP Cloud Identity Services administration console.

Provisioning Systems [page 69]
: Identity Provisioning provides connectors to various business applications for provisioning and deprovisioning of users and groups. These business applications are set up as provisioning systems in the administration console of SAP Cloud Identity Services.

Properties [page 73]
: Properties hold the configuration of a provisioning system.

Transformations [page 388]
: Transformations help you transform user and group attributes from the data model of the source system to the data model of the target system.

Users [page 509]
: Users in SAP Cloud Identity Services fall into three categories: administrators, end users, and technical users.

Agents [page 511]

Agent identity represents AI and automation agents in SAP Cloud Identity Services. Agents can authenticate, receive authorization, and be managed like human users while retaining agent-specific capabilities and security controls.

Groups [page 514]
: SAP Cloud Identity Services offers groups to organize users based on common characteristics, authorization, or application. Use them to efficiently manage user access and permissions within your organization's SAP Cloud Identity Services environment.

Authorization Policies [page 518]
: Authorization Management lets administrators control who can access what in business applications.

SAP-Managed SAP Cloud Identity [page 520]
: SAP Cloud Identity Services support both SAP-managed and customer-managed integration models, depending on who is responsible for maintaining and operating the tenant, application and provisioning configurations.

1.3.1 Tenants

A tenant refers to your (customer-specific) instance of SAP Cloud Identity Services. It's delivered to you as part of a bundle with an SAP cloud solution or as part of a self-service request in SAP BTP cockpit.

When SAP Cloud Identity Services are bundled with an SAP cloud solution, you are entitled to one productive and one test tenant preconfigured with the SAP cloud solution. If you get another solution that also bundles SAP Cloud Identity Services, you don't get additional tenant. Your existing one is reused. When your tenant is created as a result of a self-service request, it isn't preconfigured out of the box. You must set it up manually for your specific authentication and provisioning scenarios.

For more information, see Get Your Tenant [page 528] and Bundles [page 35].

Standalone tenants refer to SAP Cloud Identity Services - Identity Provisioning tenants delivered and used as a separate (standalone) product. As of October 20, 2020, Identity Provisioning is no longer sold as a standalone product. Existing customers of standalone tenants can use them as-is until the end of their contracts.

For more information, see Standalone Tenant.

Licensing and Usage

From a usage perspective, Identity Authentication, Identity Provisioning, Identity Directory, and SAP Authorization and Trust Management service are commercially included for all SAP-branded cloud solutions sold under the general terms and conditions for SAP Cloud Services, and all applications running on SAP BTP. However, you are charged for every successful authentication to SAP Cloud Identity Services from a third-party solution regardless of the protocol used. Only logon requests coming from an SAP cloud or SAP on-premise solutions are free of charge.

Logon requests are independent of the authentication mechanism and user type.

> ✤ Example
>
> *SAP Applications*

- A user wants to access SAP Build Workzone, an application that runs on SAP BTP. The application delegates authentication to Identity Authentication which is configured to act as a proxy and redirects to the corporate identity provider (IdP) for authentication. After successful authentication at the corporate IdP, Identity Authentication sends the single-sign-on (SSO) token to SAP Build Workzone. This request counts as a free of charge logon to Identity Authentication.
- A user wants to access SAP Integrated Business Planning (IBP). The user goes to Identity Authentication via a direct link. After providing the required credentials, Identity Authentication authenticates the user and sends assertion about the user to the service provider, which, in turn, validates the assertion and gives access rights to the user. Identity Authentication redirects the user to SAP IBP. This request counts as a free of charge logon to Identity Authentication.

Third-Party Applications

- A user wants to access a third-party application, which delegates authentication to Identity Authentication. The user provides a username and password and is authenticated by Identity Authentication. This request counts as a charged logon to Identity Authentication.

To get a tenant, in addition to the test and productive tenants you're already entitled to, use self-service request. You must have a global account that uses one of the consumption-based commercial models: Cloud Platform Enterprise Agreement (CPEA) or Pay-As-You-Go for SAP BTP.

For more information, see SAP Business Technology Platform Service Description Guide .

Tenant Types

Before going live, your organization most probably wants to test various tenant configurations. SAP Cloud Identity Services provide three types of tenants - productive, test, and trial.

Test tenants are used for testing purposes. Productive and test tenants have no difference from a technical and functional perspective. The tenant type flag is just a means for structuring your landscape. This means, an SAP Cloud Identity Services bundle tenant and an SAP cloud solution bundle tenant are created of one particular type: test or productive.

A trial tenant is also intended for testing purposes. However, it differs from the test one as it can be used for a limited period with a limited number of users and some other restrictions.

For more information, see Tenant Types.

Tenant Infrastructure

SAP Cloud Identity Services run on several underlying Infrastructure-as-a-Service technologies and regions. Regions are provided either by SAP or by our Infrastructure-as-a-Service (IaaS) partners Amazon Web Services (AWS), Microsoft Azure, Google Cloud. The third-party region providers operate the infrastructure layer of the regions, whereas SAP operates the platform layer.

For more information, see Regional Availability.

SAP Cloud Identity Services - Identity Authentication and Identity Provisioning tenants run on the infrastructure of SAP Cloud Identity Services.

> **Note**
>
> Identity Provisioning bundle tenants delivered before March 15, 2022, and Identity Provisioning standalone tenants delivered before September 1, 2020, run on SAP BTP, Neo environment. Customers with tenants on Neo environment are encouraged to migrate them to the SAP Cloud Identity Services infrastructure.
>
> For more information, see Migrate Identity Provisioning Bundle Tenant.

Data Center Mapping

Below is the mapping between the multi-environment subaccount in the Cloud Foundry region and the region of the Identity Authentication tenant:

Region Mapping: Cloud Foundry - Identity Authentication

IaaS Provider	Cloud Foundry - Region Name	Cloud Foundry - Region	Identity Authentication - Data Center	Infrastructure

Tenant Names

SAP Cloud Identity Services tenant, Identity Authentication tenant and Identity Provisioning tenant are sometimes used interchangeably in the documentation. However, there are some differences.

- *SAP Cloud Identity Services* tenant is an Identity Authentication tenant where Identity Provisioning service is enabled. The Identity Provisioning functionality is embedded in the SAP Cloud Identity Services admin console. The tenant runs on the SAP Cloud Identity Services infrastructure and is accessed at: `https://<ias-tenant-host>/admin`.

  > **Note**
  >
  > As of March 15, 2022, *SAP Cloud Identity Services* is the default name of the tenant.

- *Identity Authentication* tenant is a tenant where the Identity Provisioning service isn't enabled. The Identity Provisioning functionality isn't embedded in the SAP Cloud Identity Services admin console. The tenant runs on the SAP Cloud Identity Services infrastructure and is accessed at: `https://<ias-tenant-host>/admin`.
- *Identity Provisioning* tenant is a standalone or bundle tenant. It runs on the SAP BTP, Neo environment and its administration console is accessed at: `https://ips-<consumer_account>.dispatcher.<region_host>/webapp/index.html`.

1.3.1.1 Tenant Types

Identity Authentication provides three types of tenants - productive, test, and trial

> **Note**
>
> For more information about obtaining a tenant of Identity Authentication, see Tenants [page 27].

Productive and Test Tenants

Identity Authentication provides one productive and one test tenant per customer, regardless of the number of contracts signed in which Identity Authentication is included or bundled. The productive and test tenants are identical from technical and functional perspective, they only differ in the naming. Test tenants are provided to customers in addition to their productive tenants where they can test new features before implementing them productively. The test tenant is also the default identity provider for the test landscape.

> **Note**
>
> In some cases, SAP order fulfillment considers the tenant type. For example, for some test instances the trust can only be configured to Identity Authentication test tenants.

> **Restriction**
>
> A customer can't change the type of the tenant.

Trial Tenants

The trial tenant is intended for testing purposes only. It allows you to try out and explore SAP Cloud Identity Services – Identity Authentication and Identity Provisioning. It's free of charge and limited to a trial period in accordance with the SAP BTP trial terms and conditions.

> **Restriction**
>
> - You can have only one SAP Cloud Identity Services trial tenant per SAP BTP global account regardless of how many subaccounts you create. If you have multiple subaccounts, and you have trial tenants for them, they use one and the same trial tenant.
> - You can have up to 50 users in a trial tenant.
> - You can't connect to on-premise systems using the cloud connector. It's not possible to subscribe to the Cloud Identity Services connectivity plan in your trial subaccount.

- The `Invitation Rest API` is not available. For more information about the API, see Invitation REST API [page 2802].
- Email template customization is not possible.

1.3.1.2 Tenant Lifecycle

Tenants of SAP Cloud Identity Services - Identity Authentication and Identity Provisioning go through onboarding and offboarding in their lifecycle.

Onboarding

Onboarding involves all the processes needed to instantiate a tenant, configure and provision it to the customer for test or productive usage.

Tenants	Onboarding Process

• Tenants delivered as part of a bundle with an SAP cloud solution
• Tenants delivered for applications running on SAP-managed subaccounts
	1. Search for existing tenant of the customer.
	  • If one or more existing tenants are found, the existing default or the oldest one is reused.
	  The oldest (non-additional) productive and test tenants are considered default.
	  • If no existing tenant is found, a new one is created by SAP.
	2. Tenant is preconfigured for the customer.
	3. Tenant is provisioned to the customer.
	For more information, see Bundles [page 35].

Tenants delivered for applications running on customer-managed subaccounts	Tenant delivery is triggered by the customer in SAP BTP cockpit. The tenant is not preconfigured and must be configured by the customer. For more information, see Get Your Tenant [page 528] .
Tenants delivered by triggering an upgrade process in the admin tool of SAP cloud solutions **Note** This is valid for tenants bundled with SAP SuccessFactors, SAP SuccessFactors Learning and others. For more information, see Bundle Tenants and Connectors.	Tenant delivery is triggered by the customer in the administration tool of the cloud solution. In the case of SAP SuccessFactors, this is the Upgrade Center. The tenant is preconfigured for the customer. For more information, see Initiating the Upgrade to SAP Cloud Identity Services - Identity Authentication Service.

Tenants	Onboarding Process
Tenants delivered by opening a ticket to the technical component of SAP cloud solutions **Note** This is valid for tenants bundled with SAP Concur, SAP Ariba and older versions of SAP Marketing Cloud, SAP S/4HANA Cloud Public Edition. For more information, see Bundle Tenants and Connectors.	1. Customer opens a ticket to the respective technical component. 2. The support team reuses an existing tenant or creates a new one. 3. Tenant is not preconfigured and must be configured by the customer. For more information, see SAP Concur Integration Scenario.

Tenant Usage

Following the onboarding phase, tenants are provisioned to customers. They can use them as-is or configure them for their customer specific needs.

Offboarding

Offboarding leads to tenant deletion when all customer contracts for SAP cloud solutions are terminated. Depending on how the tenant is delivered, you can expect the following:

- The tenant is delivered as part of a bundling with SAP cloud solutions
  Offboarding is triggered if the customer contracts for all SAP cloud solutions are terminated or expired.

  Note

  If all of your SAP licenses are terminated, and you have a valid **SAP Concur** license, if you do not use your SAP Cloud Identity Services for 30 days, your tenant may be deleted.
- The tenant (additional tenant) is delivered as part of self-service request in SAP BTP cockpit
  Offboarding is triggered if the subscription to the Cloud Identity Services is deleted in SAP BTP cockpit. The following takes place:
  - If the tenant is obtained only for SAP BTP and no other SAP cloud solutions are reusing it, this tenant will be deleted immediately.
  - If the tenant is reused for other SAP cloud solutions, this tenant will not be deleted until all SAP cloud solutions offboard it.

  In the case of trial tenants, offboarding is triggered if the subscription to the Cloud Identity Services is deleted in SAP BTP cockpit or the SAP BTP developer trial account expired.

1.3.2 Bundles

A bundle is a group of preconfigured products and services which are sold together.

SAP Cloud Identity Services refer to a bundle as a group of preconfigured SAP cloud solutions and Cloud Identity Services. You purchase the cloud solution and get the services free of charge. The reason for bundling is to offer you out-of-the-box integration between SAP solutions.

> **Note**
>
> As a customer, you need at least one licensed SAP cloud solution which triggers SAP Cloud Identity Services tenant delivery.

The bundling process results in provisioning an SAP Cloud Identity Services tenant to your organization, where Identity Authentication and Identity Provisioning are preconfigured for the relevant SAP cloud solution. In the majority of cases, this means that in the SAP Cloud Identity Services admin console, a bundled application is created and connected to the cloud solution, where your users will log on. The trust between Identity Authentication and the given solution is established.

For Identity Provisioning, this means that communication and authentication with the provisioning systems relevant for the SAP cloud solution are set up. The transformations of those systems might be different from the default ones and adapted for specific scenarios. You are ready to schedule and run jobs to synchronize your users and groups.

Note that all provisioning systems (connectors) are enabled for the SAP Cloud Identity Access Governance bundle tenant, and all source and proxy connectors are enabled for the SAP Jam Collaboration bundle tenant.

> **Note**
>
> Note the availability of the following connectors within the bundle tenants running in the infrastructure of SAP Cloud Identity Services:
>
> - SCIM, LDAP Server, Microsoft AD, Microsoft Entra ID and Google G suite are not supported as target connectors in bundle tenants.
> - Cloud Foundry UAA Server is not supported as source, target and proxy connector in bundle tenants.

For more information, see Get Your Tenant [page 528].

SAP Cloud Solutions Bundled with Cloud Identity Services

The following SAP cloud solutions bundle with SAP Cloud Identity Services which come preconfigured for the given cloud solutions:

SAP (A-F)	SAP (G-Z)
• SAP Build Work Zone, advanced edition • SAP Business Technology Platform • SAP Central Business Configuration • Sales Cloud – Analytics & AI • SAP Cloud ALM • SAP Cloud Identity Access Governance • SAP Commerce Cloud • SAP Concur • SAP Fieldglass • SAP Field Service Management	• SAP Integrated Business Planning • SAP Jam Collaboration • SAP Marketing Cloud • SAP Market Communication for Utilities • SAP S/4HANA Cloud Public Edition • SAP SuccessFactors • SAP SuccessFactors Learning • SAP SuccessFactors Incentive Management

> **Note**
>
> Some SAP cloud solutions bundle with Identity Authentication only. There could be various reasons for that. For example, the solution may not have a local user store and therefore doesn't need to bundle with Identity Provisioning for managing identity lifecycle. Or the provisioning service doesn't offer a connector to the given SAP cloud solution.

1.3.2.1 SAP Build Work Zone, advanced edition Bundle

SAP Build Work Zone, advanced edition bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning

How to Obtain

After purchasing SAP Build Work Zone, advanced edition, you can obtain the Identity Provisioning tenant by connecting your subaccount to the service in Work Zone Manager. As the subaccount administrator, proceed as follows:

1. Connect your subaccount to Identity Provisioning as described in: Post Booster Configuration
2. Open the URL https://iamtenants.accounts.cloud.sap/ and login with your S-user.
3. View the Identity Provisioning and Identity Authentication tenants that are assigned to your customer ID.

For the complete onboarding process, see Getting Started

Related Information

SAP Build Work Zone, advanced edition

1.3.2.2 SAP Cloud Identity Access Governance Bundle

SAP Cloud Identity Access Governance bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP Cloud Identity Access Governance, if your license includes only SAP Cloud Identity Access Governance, you can obtain the Identity Provisioning as well.

> **Note**
>
> You won't be charged any extra fee as Identity Provisioning has been officially integrated in the SAP Cloud Identity Access Governance license.

You already have Identity Authentication (a mandatory service), which enables you to sign in and authenticate in the Identity Provisioning UI and within SAP Business Technology Platform.

To obtain Identity Provisioning tenant, you need to create an incident. Follow the steps:

1. Create an incident to component *GRC-IAG-OPS* (*SAP Cloud Identity Access Governance*).
2. Explain that you've purchased an SAP Cloud Identity Access Governance product and you require access to the Identity Provisioning.
3. Specify the S-user to be assigned as the first administrator of the Identity Provisioning tenants. Later, this S-user can add other users as administrators.
   For complete information on what you need to specify in the incident, see Connecting Identity Provisioning Tenant in *SAP Cloud Identity Access Governance Admin Guide*

Related Information

SAP Cloud Identity Access Governance

1.3.2.3 SAP Central Business Configuration Bundle

SAP Central Business Configuration bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

Prerequisites

- You have credentials to log in to SAP for Me. For more information, see Access and Authorizations.

How to Obtain

After purchasing SAP Central Business Configuration, you must initiate its provisioning via SAP for Me by following the procedure described in SAP for Me Online Help. If you don't have an existing SAP Cloud Identity Services tenant, this will automatically trigger its creation. If you already have a tenant, it will be reused. For more information, see Activate Your Account.

How to Use

This bundle tenant is provisioned to your organization with the following preconfigured source and target systems:

- For groups provisioning: SAP Central Business Configuration as a source system and Identity Authentication as a target system.

> **Note**
>
> Note that the default user groups for SAP Central Business Configuration are already created in Identity Authentication.

- For users provisioning: Identity Authentication as a source system and SAP Central Business Configuration as a target system.

The communication between SAP Central Business Configuration and Identity Provisioning is set up.

You receive also a preconfigured technical user in Identity Authentication for system-to-system communication.

You can review the provisioning system configurations, adjust them if needed and schedule provisioning jobs. For more information about SAP Central Business Configuration provisioning systems, see:

- SAP Central Business Configuration (Source) [page 706]
- SAP Central Business Configuration (Target) [page 1076]

The other provisioning systems in the scope of this bundle are enabled. This means that you can start adding and configuring them in the Identity Provisioning UI. See: Add New Systems [page 2415]

Related Information

SAP Central Business Configuration

1.3.2.4 SAP Commerce Cloud Bundle

SAP Commerce Cloud bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP Commerce Cloud, the technical contact person of your organization receives two onboarding e-mails from SAP. Each of them provides a tenant URL for accessing the SAP Cloud Identity Services administration console. One of the tenant URLs is for testing purposes, the other one is for productive usage. The technical contact person is granted the administrator permissions of the tenants and performs the initial logon to the SAP Cloud Identity Services administration console.

How to Use

This bundle tenant is provisioned to your organization with preconfigured source and target systems. Identity Authentication system is preconfigured as a source and SAP Commerce Cloud solution is preconfigured as a target. Identity Authentication default user groups are created for SAP Commerce Cloud.

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

1.3.2.5 SAP Concur Bundle

SAP Concur bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

Customers can integrate SAP Cloud Identity Services no matter whether the Concur instance is integrated with their own corporate identity provider or not.

Prerequisites

- New or existing Concur Expense, Concur Request, Concur Invoice, and/or Concur Travel & Expense customers that have at least one other SAP cloud solution.
- Identity Authentication and Identity Provisioning tenants must be created or configured by SAP:
  1. You need to check with your SAP Concur account team to determine if you are eligible for provisioning of a tenant with Identity Authentication and Identity Provisioning services.
  2. If eligible, create a support case to initiate the provisioning of an SAP Cloud Identity Services tenant with Identity Authentication and Identity Provisioning services. For customers with an existing Identity Authentication and Identity Provisioning tenants, the tenants will be reused.

     > **Note**
     >
     > You must create a case to set up Identity Authentication and Identity Provisioning tenant provisioning for your SAP Concur entity even if you already have existing Identity Authentication and Identity Provisioning tenants from other SAP solutions.

     To create a case, you can choose between creating an SAP for Me case (recommended) or an SAP Concur support case.
     Ensure your support case is directed correctly by using the following subject line in the short description: **`Set up SAP Cloud Identity Services for Concur`**.
     To help avoid delays due to clarification, please answer the following questions:
     - Do you have any other SAP products? (Please answer Yes or No.)
     - Are you currently using SAP Cloud Identity Services - Identity Authentication with existing SAP solutions, or is this a new setup for you?
     - What is your customer number? You can find it on the SAP for Me portal. For help accessing the portal and locating your customer number, refer to Access and Authorizations and User Action Menu (Profile).

For more information about creating an SAP for Me case, see this SAP Note: 1296527 - How to create a support case (contact SAP Product Support) - SAP for Me. Use the Component = CON-INT-SSO-SD.
For more information about creating an SAP Concur support case, see the *How to Navigate the SAP Concur Support Portal* section on the SAP Concur Support page for instructions on creating a support case. Use the Case Type = Single Sign On.

How to Use

Your approach to using SAP Cloud Identity Services for authenticating and managing users in SAP Concur solutions relies on knowing which components are automated and which ones require manual configuration.

As of June 23, 2025, SAP Concur has automated its integration with Identity Authentication, enabling you to access the SAP Cloud Identity Services administration console within SAP Concur. This automation sets up the trust between Identity Authentication and SAP Concur, including password migration.

For more information about the automated migration of user authentication and password policies from SAP Concur to SAP Cloud Identity Services, refer to Process.

For details on manual password migration, refer to Configure Authentication Provider To Migrate User Passwords from SAP Concur to Identity Authentication.

Overview

1.3.2.6 SAP Fieldglass Bundle

SAP Fieldglass bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP Fieldglass, the technical contact person of your organization receives two onboarding e-mails from SAP. Each of them provides a tenant URL for accessing the SAP Cloud Identity Services administration console. One of the tenant URLs is for testing purposes, the other one is for productive usage. The technical contact person is granted the administrator permissions of the tenants and performs the initial logon to the SAP Cloud Identity Services administration console.

How to Use

This bundle tenant is provisioned to your organization with preconfigured source and target systems.

- If you are a new SAP Fieldglass customer (greenfield scenario), you get Identity Authentication preconfigured as a source system and SAP Fieldglass preconfigured as a target.
- If you are an existing SAP Fieldglass customer (brownfield scenario), in addition to preconfigured Identity Authentication source system and SAP Fieldglass target system, you get preconfigured SAP Fieldglass source system and Identity Authentication target system. To use brownfield scenario, your SAP Fieldglass administrator must trigger an upgrade process from the SAP Fieldglass UI.

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

Related Information

SAP Fieldglass and SAP Cloud Identity Services Business Synopsis

1.3.2.7 SAP Field Service Management Bundle

SAP Field Service Management bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

Prerequisites

- You have credentials to log in to SAP for Me. For more information, see Access and Authorizations.

How to Obtain

After purchasing SAP Field Service Management, you must initiate its provisioning via SAP for Me by following the procedure described in Provisioning Environments and SAP for Me Online Help. If you don't have an existing SAP Cloud Identity Services tenant, this will automatically trigger its creation. If you already have a tenant, it will be reused. For more information, see Get Your Tenant.

> **Note**
>
> If the SAP Cloud Identity Services - Identity Authentication tenant is newly created the technical contact person of your organization is added as administrator of this tenant. If the tenant is reused, the technical contact person of your organization is added as a regular user. In case a user with matching email address already exists in the SAP Cloud Identity Services - Identity Authentication tenant, no additional user is created. In that case no activation email is sent from SAP Cloud Identity Services.

When the provisioning is complete, the technical contact person of your organization receives an email which contains the URL to the console of Field Service Management and the Account Name. For more information, see Initial System Access.

How to Use

This bundle tenant is provisioned to your organization with preconfigured provisioning systems. Also, the communication between SAP Field Service Management and Identity Provisioning is set up. You have preconfigured technical users in Identity Authentication and SAP Field Service Management for system-to-system communication.

The authentication flow from SAP Field Service Management is set up through OpenID Connect with the Identity Authentication.

You have the following provisioning systems preconfigured:

- For external users provisioning: SAP Field Service Management as a source system and Identity Authentication as a target system.
- For employee users provisioning: Identity Authentication as a source system and SAP Field Service Management as a target system. The source system has set filter to provision only employee users assigned to groups with `groups.display` starting with `"FSM_"`.

Additionally, you have automatically enabled real-time provisioning for external users from SAP Field Service Management to Identity Authentication and a technical user for accessing the real-time provisioning API.

You can review the provisioning system configurations, adjust them if needed and schedule provisioning jobs. For more information about SAP Field Service Management provisioning systems, see:

- SAP Field Service Management (Source) [page 757]
- SAP Field Service Management (Target) [page 1140]

The other provisioning systems in the scope of this bundle are enabled. This means that you can start adding and configuring them in the Identity Provisioning UI. See: Add New Systems [page 2415]

1.3.2.8 SAP Integrated Business Planning Bundle

SAP Integrated Business Planning (in short, SAP IBP) bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

Since November 2022, the Identity Provisioning service is provided together with SAP IBP by default. For information about accessing your Identity Provisioning tenant as an administrator, see Initial Administrator User. If your system has been provisioned before November 2022, you can obtain an Identity Provisioning bundle tenant by creating an incident as follows:

1. Create an incident to component *SCM-IBP-OPS-SRV* (*Cloud Operations Service Requests*).
2. Specify the S-user to be assigned as the first administrator of the Identity Provisioning tenants. Later, this S-user can add other users as administrators.
3. Specify the URLs to your SAP IBP **Quality** and **Productive** systems.

In the reply of your incident, you'll receive two URLs related to two Identity Provisioning tenants.

- The first URL will be bound to your **Quality** instance, and you can use it for testing purposes.
- The second URL will be bound to your **Productive** instance, and you can use it for productive provisioning configurations and jobs. This bounding principle is applied to your Identity Authentication tenants as well.

If you encounter issues with accessing your Identity Provisioning UI, create an incident to component *BC-IAM-IPS*.

How to Use

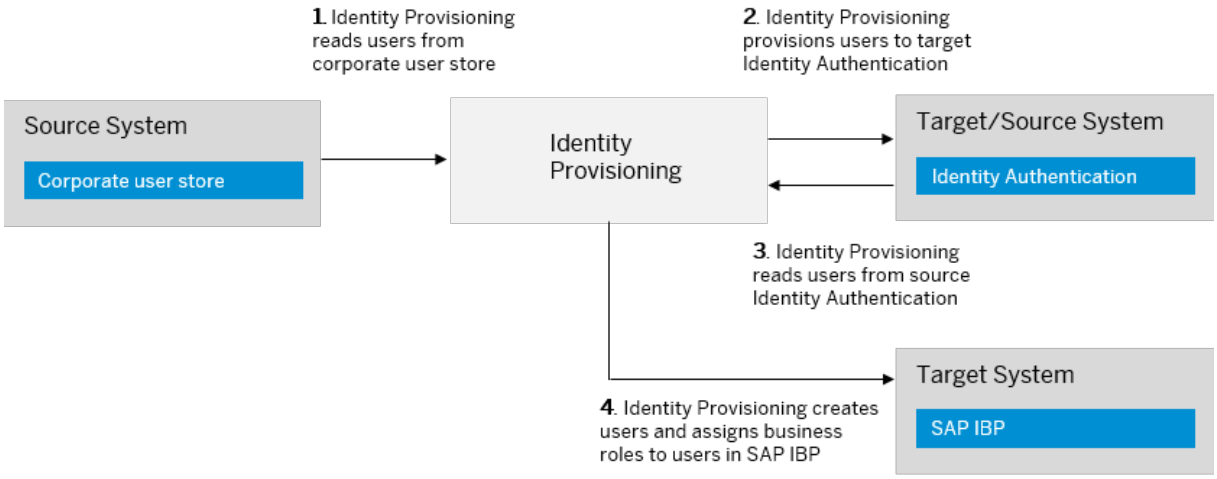
The scope of the SAP IBP bundle tenant includes the provisioning systems (connectors) displayed in the diagram above.

By default, the communication between SAP IBP and Identity Provisioning is automatically set up. Also, Identity Authentication is preconfigured as a source system and SAP IBP is preconfigured as a target system. This means that you can start running provisioning jobs manually or set a time interval for scheduled jobs. See: Start and Stop Provisioning Jobs [page 2472]

The other provisioning systems in the scope of this bundle are enabled. This means that you can start adding and configuring them in the Identity Provisioning UI. See: Add New Systems [page 2415]

> **Note**
>
> Users and groups in Identity Authentication correspond to business users and business roles in SAP IBP. The user groups defined in SAP IBP are not considered by the Identity Provisioning.

> **Example**
>
> In this example scenario, users are first provisioned to Identity Authentication (target system) from a corporate user store, such as Microsoft Azure AD (source system). Afterwards, those users are provisioned from Identity Authentication (this time set up as a source system) to SAP IBP (target system).



For more information about SAP IBP integration scenarios, see: Integrating Identity Provisioning Service with SAP IBP

For more information about the provisioning systems (source, target and proxy) relevant to SAP IBP bundle, see: Supported Systems [page 585]

SAP Integrated Business Planning

1.3.2.9 SAP Jam Collaboration Bundle

SAP Jam Collaboration bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

- **Your license contains Identity Provisioning**
  After purchasing SAP Jam Collaboration, you'll receive two e-mails from SAP. According to your contract with SAP, a technical contact person has been chosen as the first user of the Identity Provisioning service, who is granted with *Administrator* permissions. In these e-mails from SAP, you'll find the ID of this administrator (their P- or S-user) and their e-mail address. They can access the Identity Provisioning UI with their user credentials.
  Each e-mail from SAP contains also a URL link that you, as an administrator, can use to directly access the Identity Provisioning UI. These two URLs are related to two different Identity Provisioning tenants – the first one you can use for *testing* purposes, and the second one – for *productive* provisioning configurations and jobs.

If you encounter issues with accessing your Identity Provisioning UI, create an incident to component *BC-IAM-IPS*.

- **Your license does not contain Identity Provisioning**
  After the successful purchase, if your license includes only SAP Jam Collaboration, you can request a tenant for the Identity Provisioning service.

  > **Note**
  >
  > You won't be charged any extra fee as Identity Provisioning service has been officially integrated in the SAP Jam license.
  >
  > See the following blog post: SAP Jam now comes with the Identity Provisioning service

  You already have Identity Authentication (a mandatory service), which enables you to sign in and authenticate in the Identity Provisioning UI and within SAP Business Technology Platform.
  To obtain Identity Provisioning, you need to create an incident. Follow the steps:
  1. Create an incident to component *BC-IAM-IPS*.
  2. Explain that you've purchased an SAP Jam Collaboration product and you require access to the Identity Provisioning service.
  3. Specify the S-user to be assigned as the first administrator of the Identity Provisioning tenants. Later, this S-user can add other users as administrators.

How To Use

If your SAP Jam Collaboration license includes Identity Provisioning, this bundle tenant is provisioned to your organization with preconfigured source and target systems. Identity Authentication system is preconfigured as a source system and SAP Jam Collaboration is preconfigured as a target. For more information, see Identity Authentication and Identity Provisioning in the *SAP Jam Collaboration Administrator Guide*.

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

Related Information

SAP Jam Collaboration

1.3.2.10 SAP Marketing Cloud Bundle

SAP Marketing Cloud bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

You have purchased the product before release 1911

If you've bought SAP Marketing Cloud before the **1911** release, you have to request access to the Identity Provisioning service. To do this, follow the steps:

1. Create an incident to component *XX-S4C-OPR-SRV* (*S/4HANA Cloud service requests*).
2. Explain that you've purchased an SAP Marketing Cloud product before **1911** release.
3. Specify the S-user to be assigned as the first administrator of the Identity Provisioning tenants. Later, this S-user can add other users as administrators.
4. Specify the URLs to your SAP Marketing Cloud **Quality** and **Productive** systems.

In the reply of your incident, you'll receive two URLs related to two Identity Provisioning tenants. The first URL will be bound to your **Quality** instance, and you can use it for *testing* purposes. The second URL will be bound to your **Productive** instance, and you can use it for *productive* provisioning configurations and jobs. This bounding principle is applied to your Identity Authentication tenants as well.

You have purchased the product after release 1911

If you've bought SAP Marketing Cloud with release **1911** or higher, you'll receive two onboarding e-mails from SAP. According to your contract with SAP, a technical contact person has been chosen as the first user of the Identity Provisioning service, who is granted with *Administrator* permissions. Each onboarding e-mail contains a URL link that you, as an administrator, can use to directly access the Identity Provisioning UI. The relevant URLs are related to two different Identity Provisioning tenants – the first one you can use for *testing* purposes, and the second one – for *productive* provisioning configurations and jobs.

If you encounter issues with accessing your Identity Provisioning UI, create an incident to component *BC-IAM-IPS*.

SAP Marketing Cloud

1.3.2.11 SAP Market Communication for Utilities Bundle

SAP Market Communication for Utilities bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP Market Communication for Utilities, the technical contact person of your organization receives two onboarding e-mails from SAP. Each of them provides a tenant URL for accessing the SAP Cloud

Identity Services administration console. One of the tenant URLs is for testing purposes, the other one is for productive usage. The technical contact person is granted the administrator permissions of the tenants and performs the initial logon to the SAP Cloud Identity Services administration console.

How to Use

This bundle tenant is provisioned to your organization with preconfigured source and target systems.

The Identity Authentication system (named **IAS for MaCo – source**) is configured as the source, while the SAP Market Communication for Utilities system (named **MaCo-<subdomain>**) is configured as the target that reads from this source.

Default user groups for SAP Market Communication for Utilities are created in Identity Authentication. Communication between SAP Market Communication for Utilities and Identity Provisioning is already established, using **ClientCertificateAuthentication**. For more information, see What has the system automatically prepared for the synchronization?.

> **Note**
>
> A single SAP Cloud Identity Services tenant with configured Identity Authentication source system is used for provisioning to all SAP Market Communication for Utilities tenants that you obtain.

The transformations in the preconfigured systems (provided below) differ from the default Identity Provisioning transformations in Identity Authentication (source system) [page 586] and SAP Market Communication for Utilities (target system) [page 1187], as they are adapted to the scenarios relevant to this bundle.

Identity Authentication (source system)

        ]
    }
}
```

In addition, bulk operations are enabled for the SAP Market Communication for Utilities target. The following properties are configured:

- maco.bulk.operations.max.count = 50
- maco.support.bulk.operation = true
- maco.user.roles.overwrite = false
- maco.hr.switch.active = false
- ips.date.variable.format = yyyy-MM-dd

For more information about these properties, see List of Properties [page 80].

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

For more information on the manual tasks you can perform, see What do you need to do manually?.

1.3.2.12 SAP S/4HANA Cloud Public Edition Bundle

SAP S/4HANA Cloud Public Edition bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

The way you obtain Identity Provisioning bundle tenant depends on the release of your SAP S/4HANA Cloud Public Edition.

SAP S/4HANA Cloud Public Edition Purchased Before 1911 Release

If you've purchased SAP S/4HANA Cloud Public Edition before the **1911** release, you have to request access to the Identity Provisioning service. To do this, follow the steps:

1. Create an incident to component *XX-S4C-OPR-SRV* (*S/4HANA Cloud service requests*).
2. Explain that you've purchased an SAP S/4HANA Cloud Public Edition product before **1911** release.
3. Specify the S-user to be assigned as the first administrator of the Identity Provisioning tenants. Later, this S-user can add other users as administrators.

In the reply of your incident, you'll receive two URLs related to two Identity Provisioning tenants. The first URL will be bound to your **Quality** instance, and you can use it for *testing* purposes. The second URL will be bound to your **Productive** instance, and you can use it for *productive* provisioning configurations and jobs. This bounding principle is applied to your Identity Authentication tenants as well.

SAP S/4HANA Cloud Public Edition Purchased With 1911 Release or Higher

If you've purchased SAP S/4HANA Cloud Public Edition with release **1911** or higher, you'll receive two onboarding e-mails from SAP. According to your contract with SAP, a technical contact person has been chosen as the first user of the Identity Provisioning service, who is granted with *Administrator* permissions. Each onboarding e-mail contains a URL link that you, as an administrator, can use to directly access the Identity Provisioning UI. The relevant URLs are related to two different Identity Provisioning tenants – the first one you can use for *testing* purposes, and the second one – for *productive* provisioning configurations and jobs.

How to Use

The Identity Provisioning bundle tenant for SAP S/4HANA Cloud Public Edition release 1911 or higher comes with preconfigured provisioning systems (connectors) for specific integration scenarios:

- For integrating SAP S/4HANA Cloud Public Edition with the embedded SAP Analytics Cloud, SAP provides preconfigured SAP S/4HANA Cloud Public Edition source system and SAP Analytics Cloud target system. To learn more about what's been initially preconfigured and how to apply subsequent changes to the Identity Provisioning configurations, see:
  - Ensure SAP S/4HANA Cloud Public Edition users are replicated during their validity period
  - Ensure deleted SAP S/4HANA Cloud Public Edition users are also deleted in SAP Analytics Cloud
- For integrating SAP S/4HANA Cloud Public Edition with Identity Authentication, SAP provides preconfigured Identity Authentication source system and SAP S/4HANA Cloud Public Edition target

system. Also preconfigured Identity Authentication source system and SAP Central Business Configuration target system are delivered with system provisioning.

> **Note**
>
> Your initial provisioning jobs are paused. This means, you need to manually run them. To do this, open your relevant source systems, go to the *Jobs* > *Read Job* > *Schedule* and turn the job scheduler *ON*. For more information, see Read Provisioning Job [page 2474] . If you need to, correct the credentials (users and passwords) for your relevant systems first, and then start the initial job(s).

If you encounter issues with accessing your Identity Provisioning UI, create an incident to component *BC-IAM-IPS*.

Related Information

SAP S/4HANA Cloud Public Edition

SAP Identity Provisioning (IPS) is now bundled with SAP S/4HANA Cloud Public Edition!

1.3.2.13 SAP SuccessFactors Bundle

SAP SuccessFactors bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

If your SAP SuccessFactors tenant was created after December 9, 2022, Identity Authentication and Identity Provisioning have already been enabled. You do not need to complete the steps to upgrade to Identity Authentication, as described in Initiating the Upgrade to SAP Cloud Identity Services - Identity Authentication Service.

How to Obtain

After purchasing SAP SuccessFactors, if your license includes only SAP SuccessFactors, you can obtain Identity Authentication and Identity Provisioning as well. To do this, you have to enable these services via the *Upgrade Center* of SAP SuccessFactors. You need to provide an S-user and password for validation. This S-user will be assigned as the first administrator of the Identity Provisioning tenants.

> **Note**
>
> In case you already have an existing Identity Provisioning tenant, its initial administrator may be different than the S-user you've provided in the *Upgrade Center* procedure. Due to security reasons, this S-user will not be assigned as an administrator. If you want it to be granted IPS_ADMIN permissions, you need to ask the initial Identity Provisioning administrator to do that for you. To learn how, see: Manage Authorizations
>
> See also: (Guided Answers) Can't Get Admin Permissions for a Bundle

You also need to create a password for the automatically created SAP SuccessFactors API user (*IPSADMIN*), and grant it the following permissions:

- Go to *Admin Center* > *Manage Permission Roles* > *Manage Integration Tools* and choose "*Allow Admin to Access OData API through Basic Authentication*".
- Go to *Admin Center* > *Manage Permission Roles* > *Administrator Permission* > *Manage User* and choose "*User tenant OData entity*".

Proceed as follows:

1. Getting Started with Identity Authentication and SAP SuccessFactors
2. Initiate Upgrade to Identity Authentication
3. Identity Provisioning Administration Console Tasks
4. Setting an API User for Sync Jobs

Your Identity Provisioning system is created once you've initiated your upgrade to Identity Authentication, and the Identity Provisioning administrator receives an email with two links to the Identity Provisioning admin console (related to two different tenants) – one for *testing* purposes, and one – for *productive* provisioning configurations and jobs.

If the upgrade procedure fails, create an incident to component *LOD-SF-PLT-IAS*.

If you have troubles with the Identity Provisioning admin console or configurations, create an incident to component *BC-IAM-IPS*.

How to Use

This bundle tenant is provisioned to your organization with preconfigured source and target systems. SAP SuccessFactors is preconfigured as a source system and Identity Authentication is preconfigured as a target.

Integrating SAP SuccessFactors with the embedded SAP Analytics Cloud is triggered from SAP SuccessFactors *Upgrade Center*. As a result, SAP Analytics Cloud is created as a target system. It is disabled and no source system is linked to it.

> **Note**
>
> SAP SuccessFactors target system is enabled only for Identity Provisioning bundle tenants running on SAP Cloud Identity Services infrastructure.

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

Related Information

SAP SuccessFactors Platform

1.3.2.14 SAP SuccessFactors Incentive Management Bundle

SAP SuccessFactors Incentive Management, formerly known as SAP Commissions, bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP SuccessFactors Incentive Management, you'll receive two e-mails from SAP. According to your contract with SAP, a technical contact person has been chosen as the first user of the Identity Provisioning service, who is granted with *Administrator* permissions. In these e-mails from SAP, you'll find the ID of this administrator (their P- or S-user) and their e-mail address. They can access the Identity Provisioning UI with their user credentials.

Each e-mail from SAP contains also a URL link that you, as an administrator, can use to directly access the Identity Provisioning UI. These two URLs are related to two different Identity Provisioning tenants – the first one you can use for *testing* purposes, and the second one – for *productive* provisioning configurations and jobs.

Related Information

SAP SuccessFactors Incentive Management

1.3.2.15 SAP SuccessFactors Learning Bundle

SAP SuccessFactors Learning bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing SAP SuccessFactors with license for SAP SuccessFactors Learning, you can obtain Identity Authentication and Identity Provisioning tenants by initiating the integration in SAP SuccessFactors *Upgrade Center* as outlined here: How to Integrate SAP SuccessFactors Learning and SAP Cloud Identity Services

The process to integrate SAP SuccessFactors Learning and SAP Cloud Identity Services - Identity Authentication and Identity Provisioning consists of the following four steps:

1. Initiating Learning Identity Authentication Migration
2. Learning Configuration Procedure
3. Migrating Learning Users to Identity Authentication
4. Identity Authentication Activation

How to Use

This bundle tenant is provisioned to your organization with preconfigured source and target systems. SAP SuccessFactors Learning is preconfigured as a source system and Identity Authentication is preconfigured as a target.

You can review the provisioning system configurations, adjust them if needed and schedule read jobs.

1.3.2.16 Sales Cloud – Analytics & AI Bundle

Sales Cloud – Analytics & AI bundles with SAP Cloud Identity Services – Identity Authentication and Identity Provisioning.

How to Obtain

After purchasing Sales Cloud – Analytics & AI, you'll receive two e-mails from SAP. According to your contract with SAP, a technical contact person has been chosen as the first user of the Identity Provisioning service, who is granted with *Administrator* permissions. In these e-mails from SAP, you'll find the ID of this administrator (their P- or S-user) and their e-mail address. They can access the Identity Provisioning UI with their user credentials.

Each e-mail from SAP contains also a URL link that you, as an administrator, can use to directly access the Identity Provisioning UI. These two URLs are related to two different Identity Provisioning tenants – the first one you can use for *testing* purposes, and the second one – for *productive* provisioning configurations and jobs.

1.3.2.17 SAP Cloud ALM Bundle

SAP Cloud ALM bundles with SAP Cloud Identity Services – Identity Authentication.

Prerequisites

You have an S-user with the role *Edit Cloud Data* on SAP for Me in order to request SAP Cloud ALM.

How to Obtain

SAP Cloud ALM helps you to implement and operate intelligent cloud and hybrid business solutions. SAP Cloud ALM is included in your **cloud** subscription containing Enterprise Support, cloud edition and in SAP Enterprise

Support. You can request SAP Cloud ALM on SAP for Me for yourself or for all entitled customers for whom you have sufficient permissions. If you don't have an existing productive SAP Cloud Identity Services tenant, this will automatically trigger its creation. If you already have a productive tenant, it will be reused, except for the cases in which it cannot be used due to some restrictions and legal requirements. For more information, see Requesting SAP Cloud ALM and Get Your Tenant [page 528].

> **Note**
>
> The user who requested SAP Cloud ALM receives permissions that are required for administrative tasks in the SAP BTP cockpit and in SAP Cloud ALM. Additionally, if the SAP Cloud Identity Services tenant is newly created this user is added as administrator of this tenant. If the tenant is reused, the user is added as a regular user. In case a user with matching email address already exists in the SAP Cloud Identity Services tenant, no additional user is created. In that case no activation email is sent from SAP Cloud Identity Services.

When the provisioning of SAP Cloud ALM is complete, the requesting user receives emails containing sign in information, configuration guidance, and links to support resources.

How to Use

This bundle tenant is provisioned to your organization in a newly created SAP BTP customer-managed subaccount. An OIDC trust is preconfigured between your Identity Authentication tenant and your SAP BTP multi-environment subaccount with enabled Cloud Foundry environment. Identity Authentication is set as trusted identity provider. This means that the way business users are signing in to SAP Cloud ALM is based on the configuration in the Identity Authentication.

You receive also the following attributes preconfigured:

- The home URL of SAP Cloud ALM is configured. For more information, see Configure an Application's Home URL [page 1937].
- The `e-mail` is configured as `Name ID` attribute in the settings of your identity provider. For more information, see Configure the Subject Name Identifier Sent to the Application [page 1988].
- The default assertion attributes for the established OIDC trust are configured. For more information, see Customizing Attribute Mappings.

After the provisioning of SAP Cloud ALM is complete, a few setup steps are required so that it can be used productively. For more information, see Required Setup for SAP Cloud ALM. To give further users access to SAP Cloud ALM, see Onboard Users in the Identity Authentication Service.

Related Information

SAP Cloud ALM
Monitoring with SAP Cloud ALM [page 2991]

1.3.3 Applications

An application is associated with a consumer of Identity Authentication as an identity provider. This consumer could be for example an SAP cloud solution, a third-party application, SAP BTP subaccount, or the SAP Cloud Identity Services administration console.

The application holds the configuration information about trust, authentication, access, and branding of the given consumer. SAP and customers create applications in SAP Cloud Identity Services administration console. The following table describes the different types of applications, who is in charge of them and whether they are configurable or not:

Created By	Application Type	Application Display Name	Specifics
SAP	*Bundled Applications*	For example: *S4HANA Cloud* - `<s4-tenant-type>`	SAP creates bundled applications and is in charge of their configuration.
	System Applications	*Administration Console*	SAP creates and preconfigures the administration console as a system application.
		User Profile	SAP creates and preconfigures the profile page with some personal information.
	Subscribed Applications	For example: *SAP BTP* `<subaccount display name>`	Subscribed applications are associated with an SAP BTP subaccount or an application registered there. These applications are automatically created for you. You can't create or delete them.
Customer	*Charged Applications*	For example: *Microsoft Entra ID*	Charged applications are created by customers for third-party (non-SAP) solutions. Customers are in charge of the configuration and are charged for integrating applications with Identity Authentication.

Created By	Application Type	Application Display Name	Specifics
	Bundled Applications	For example: *SAP Concur*	Apart from SAP, bundled applications can also be created by customers. This applies for SAP cloud applications that do not bundle the delivery and preconfiguration of the SAP Cloud Identity Services.

Applications are sometimes referred to as SAML 2.0 applications or OpenID Connect applications depending on the configured protocol. Some software-as-a-service applications and the `Administration Console` application support both protocols and display the hybrid `SAML 2.0 & OpenID Connect` protocol type. The SAML 2.0 standard defines applications as service providers, while OpenID Connect (OIDC) defines them as relying parties.

For more information, see Application Types [page 63] and Configuring Applications [page 1920].

SAP-Managed SAP Cloud Identity [page 520]

1.3.3.1 Application Types

Application types in the administration console for SAP Cloud Identity Services.

SAP Applications

The SAP applications are created and managed by SAP, and they can't be deleted. Part of their configurations are read-only. SAP applications are: bundled, subscriptions and system applications.

Identity Authentication identifies the type of the application by the URI or SAML 2.0 endpoints.

> ⓘ Note
>
> Applications using custom domains can't be marked correctly, so if you have such applications, report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

Bundled Applications

Bundled applications are managed and configured by SAP and can't be deleted. Part of their SAML 2.0 configurations are read-only. For more information, see Configure an Application's Type [page 1935].

Subscribed Applications

A special kind of applications are the so-called subscribed applications.

Most subscribed applications use the trust configuration of the SAP BTP subaccount where they're subscribed. For some applications, when you subscribe to them, the system automatically sets up an application in Identity Authentication for you. These applications appear as child applications of the application in SAP Cloud Identity Services that represents the SAP BTP subaccount.

You can't create or delete a subscribed application. For these applications, you can only see and configure a certain subset of their settings. The change in the following configurations is restricted, since they are managed by the application provider:

- Protocol
- OpenID Connect Configuration

  > ⓘ Note
  >
  > It's possible to add custom URIs, but those defined by the application provider remain.

- Attributes - Self-defined Attributes
  The attributes supported by subscribed applications are predefined and listed under the *Primary Attribute* section, with default mappings for source *Identity Directory*. You can see which attributes are supported, and add or remove mappings for the other sources - *Corporate Identity Provider* and *Expression*.

  > → Tip
  >
  > For some subscribed applications, you might need to add custom attribute mappings (under the *Self-Defined Attributes* section).

- Client Authentication

  > ⓘ Note
  >
  > Fully managed by the application provider.

- APIs

  > ⓘ Note
  >
  > You have no access to the APIs provided by Identity Authentication.

System Applications

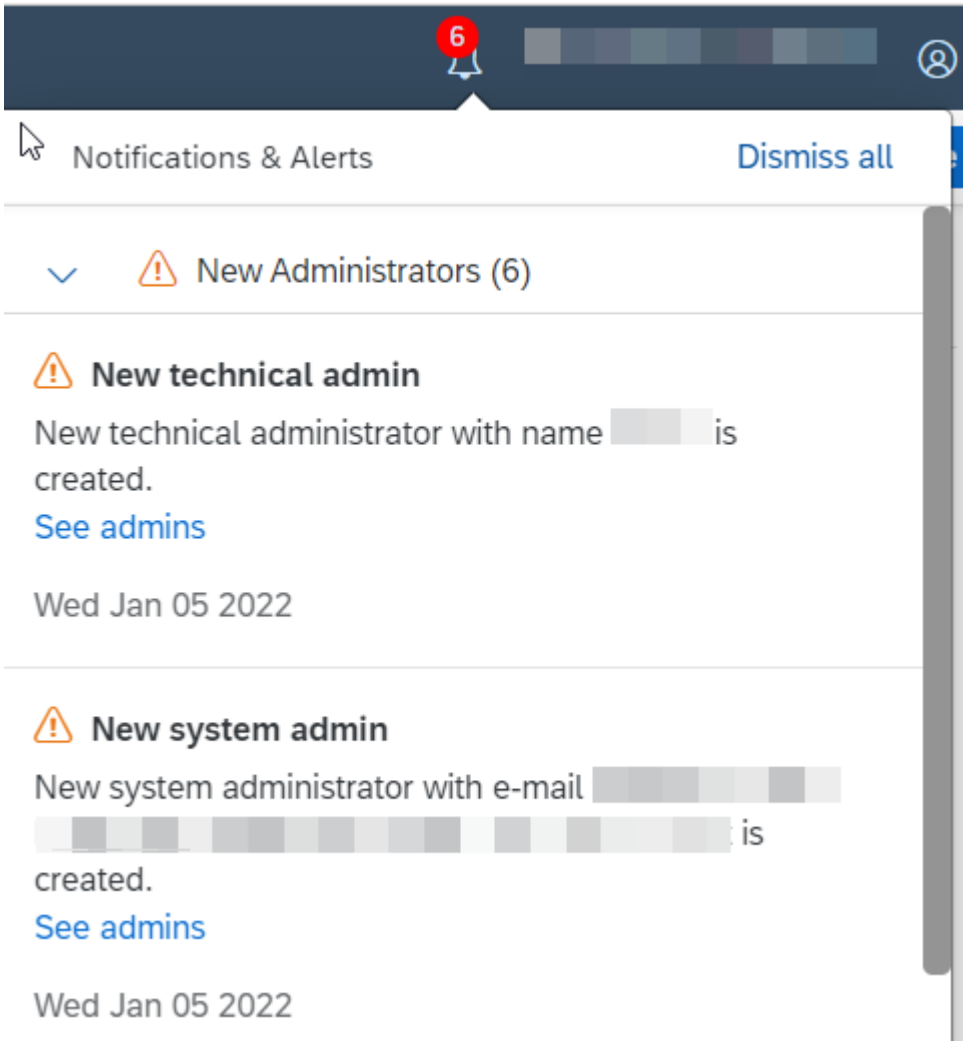
The tenant of Identity Authentication has two additional system applications. They are predefined with the creation of the tenant. These applications are: `Administration Console`, and `User Profile`, previously called `SAP Cloud Identity`.

> ⓘ Note
>
> In some tenants, the `User Profile` application still bears its previous name, `SAP Cloud Identity`.

> → Tip
>
> If `Administration Console` or `User Profile` are not in the list of the system applications you may request them. To do this, report an incident on SAP Support Portal Home under the component `BC-IAM-IDS`.

> ⚠ Caution
>
> Please be careful when you make configuration changes to the system applications. Certain configuration options for the system applications are read-only.
>
> System applications can't be parents to other applications, and can't have child applications.

The `Administration Console` application contains the configurations of the administration console for SAP Cloud Identity Services, and information about expiring certificates, system notifications and new administrators. The information is visible at the top-right corner of the administration console:



You can access the tenant's administration console for SAP Cloud Identity Services by using the console's URL.

> **Note**
>
> The URL has the following pattern:
>
> `https://<tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin`
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].
>
> If you have a configured custom domain, the URL has the `<your custom domain>/admin` pattern.
>
> If you have updated the `Name` in the *SAML 2.0 Configuration* or the `URL` in the *OpenID Connect Configuration* in *Tenant Settings* make sure to access the tenant with the updated domain in the `Name`

or **URL**. For more information, see Tenant SAML 2.0 Configurations [page 2103] and Tenant OpenID Connect (OIDC) Configurations [page 2117].

As a tenant administrator you can change the default configurations:

- to configure stronger protection for the administration console for SAP Cloud Identity Services via the *Risk-Based Authentication* option.
- to configure stronger password requirements for the tenant administrators of the administration console for SAP Cloud Identity Services.
- to choose authenticating identity provider and define rules for authenticating identity provider.
- to customize the look and feel of the sign-in page of the administration console for SAP Cloud Identity Services.

→ Tip

To change the appearance of the administration console, at the top-right corner choose the *circle with your initials* > *Settings* > *Appearance* and select the theme you want. You can chose from:

- *SAP Morning Horizon (default)*
- *SAP Evening Horizon*
- *SAP Quartz Light*
- *SAP Horizon High Contrast White*
- *SAP Horizon High Contrast Black*

The `User Profile` application contains the configurations of the Profile Page.

As a tenant administrator you can change the default configurations:

- to configure stronger protection via the *Risk-Based Authentication* option.
- to choose authenticating identity provider and define rules for authenticating identity provider.
- to define custom email template sets for users created via the *Add User* option in the administration console for SAP Cloud Identity Services, or via the SCIM REST API.
- to customize the look and feel of the sign-in page of the Profile Page.

ⓘ Note

The URL of the profile page has the following pattern:

`https://<tenant ID>.accounts.ondemand.com` or `https://<tenant ID>.accounts.cloud.sap`

Tenant ID is an automatically generated ID by the system.

If you have a configured custom domain, the URL is `<your custom domain`.

→ Tip

For a quick access to your own profile page, at the top-right corner of the administration console, choose the *circle with your initials* > *Settings* > *User Account* > *Manage Profile*. Your profile page opens in a new tab.

Customer Applications

Applications that are created by the SAP customers are recognized as charged, or third-party applications. If no URI or SAML 2.0 endpoints are specified in the configuration of the application, Identity Authentication recognizes the application as a charged one.

Charged applications are created by customers for third-party (non-SAP) solutions. Customers are in charge of the configuration and are charged for integrating applications with Identity Authentication.

All the configurations of the applications are done by you as a customer.

Parent, Child Applications

SAP and non-SAP created applications can also be parent or child. An application can be defined as parent or child at its creation, or later when editing the application.

When you create or edit an application, you can select a parent for that application. Thus, the application that is created or edited becomes child, and the selected application becomes parent. When creating a new application, the parent application option in the administration console is optional.

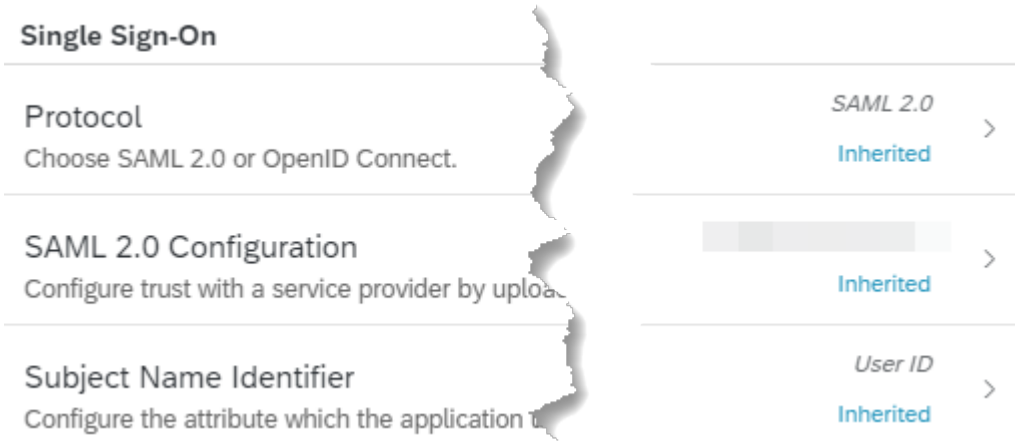
Changing child application's configuration doesn't affect the configuration of the parent.

Applications that have a parent application configured can't be selected as parent application.

An application that is chosen as a parent application to another can't have a parent application assigned for it.

Newly created applications with an assigned parent application inherits all the configurations from the parent with the except for the `Client ID` and `Secrets`.

The inherited configurations are marked as such.



Existing applications that have a parent application assigned to them will inherit only the configurations that have not been changed, including the configurations that are made at the creation of the application. The configurations that are changed, and the configurations made at the creation of the application are not inherited. See the list below for the configurations made at the creation of the application:

- Protocol

- Subject Name Identifier

  > **Note**
  >
  > When a subscribed application becomes a child application, the configuration of the `Subject Name Identifier` of that child application can be different from the parent application or from the application it is subscribed to. You can make the configuration of the `Subject Name Identifier` the same as the parent application by choosing the *Inherit from Parent* button on the top right-hand corner of the screen. You can also make the configuration of the `Subject Name Identifier` the same as the application it is subscribed to by choosing the *Reset* button on the top right-hand corner of the screen. Depending on your configuration, either the *Inherit from Parent* or the *Reset* button is active, or both buttons are active.

- Default Name ID Format
- Attributes

  > **Note**
  >
  > Attributes from different sources are inherited separately. For more information about the different user attribute sources, see User Attributes [page 1972].

- Dependencies
- Risk-Based Authentication
- Conditional Authentication
- Email Verification
- Password Policy
- Terms Of Use
- Privacy Policy
- User Application Access
- User Attributes for Access
- Token Url Separator
- Reload Parent Page

> **→ Tip**
>
> A child application can override all the configurations inherited from the parent application. If you change a configuration in the child that is inherited from the parent, and after that you decide to return to the inherited one, go to the respective configuration and choose the *Inherit from Parent* button on the top right-hand corner of the screen.

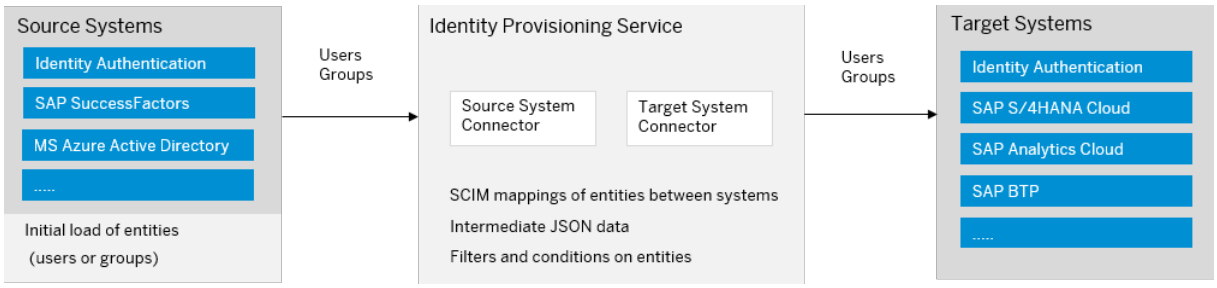
> **⚠ Caution**
>
> If you change a configuration in the child that is inherited from the parent, also change the name of the child, so that it differs from the name of the parent. Saving the configuration without changing the child application's name may result in failing authentication requests.

1.3.4 Provisioning Systems

Identity Provisioning provides connectors to various business applications for provisioning and deprovisioning of users and groups. These business applications are set up as provisioning systems in the administration console of SAP Cloud Identity Services.

Similar to applications in Identity Authentication, provisioning systems can be viewed as abstractions of the business applications, where these abstractions are used for the purposes of Identity Provisioning.

A provisioning system configured for reading users and groups is called source system. The source system is usually the user store of your organization. A provisioning system used for replicating users and groups is called target system. The target system is usually a cloud system with local user store, where entities are provisioned to from one or more source systems.



The main use case of Identity Provisioning is to read users and groups from a source system and provision them to a target system. This is the standard provisioning mode illustrated in the diagram above.

Identity Provisioning can also be used in proxy mode. In this mode, the service is used for synchronizing user data to and from a central identity management solution (for example, the on-premise SAP Identity Management) and a provisioning system - called proxy system (for example, SAP Analytics Cloud, embedded edition). Here, Identity Provisioning acts as a proxy between the identity management solution and the system with proxy configuration.

For more information, see System Types and Supported Systems.

SAP-Managed SAP Cloud Identity [page 520]

1.3.4.1 System Types

Identity Provisioning categorizes systems based on the method of creation, usage and underlying protocols.

Creation

There are two types of provisioning systems based on the method of creation: customer managed and SAP initiated.

Customer Managed

These are the provisioning systems that you as a customer create and configure in the Identity Provisioning UI. There is a limit to the number of systems you can create. It is 20 for source systems and 50 or target systems. However, if your scenarios require more provisioning systems, open an incident for component **BC-IAM-IPS** to request them.

SAP Initiated

These are the provisioning systems that are automatically created and preconfigured in the Identity Provisioning UI. There is no limit to the number of systems created for you by SAP. Furthermore, you can modify their initial configuration to make them suitable for your scenario.

Usage

There are three types of provisioning systems based on their usage: *Source*, *Target*, and *Proxy*. All three of them can be created as customer managed and SAP-initiated systems.

Source Systems

A source system is the connector used for reading entities (users, groups, roles). Source systems can be on-premise or cloud-based, SAP or non-SAP, and usually represent the corporate user store where identities are currently maintained. Identity Provisioning reads the entities from the source system and creates or updates them in the relevant target ones. The provisioning is triggered from the Jobs tab of a source system.

You can connect one source system to one or multiple target systems.

> ⓘ Note
>
> In the case of multiple (enabled) target systems, when you start a *Read* or a *Resync* job, this operation will trigger provisioning of entities from this source system to all relevant target ones.

To check the list of all supported source systems, see: Source Systems [page 585]

Target Systems

A target system is the connector used for writing (provisioning) entities. Target systems are usually clouds, where Identity Provisioning creates or updates the entities taken from the source system.

A target system can be connected to a single or multiple source systems.

> **Note**
>
> In the case of multiple source systems, we recommend that you run the provisioning jobs successively for each system, not simultaneously. This way, you'll avoid incorrect overwriting or merging of entity data, hence failed provisioning jobs.

To check the list of all supported target systems, see: Target Systems [page 936]

Proxy Systems

A proxy system is a special connector used for "hybrid" scenarios. It exposes any Identity Provisioning supported backend system as a SCIM 2.0 service provider, which can be consumed by any SCIM 2.0 compatible client application, without making a direct connection between them.

To achieve this, the Identity Provisioning service uses this special proxy system to execute provisioning operations (create, update, delete, etc.) requested by the client application.

The examples in this section cover using of SAP Identity Management as a consuming client application but you can use any other SCIM-based identity management solution. For more information, see: Hybrid Scenario: SAP Identity Management [page 2961]. To provide communication between SAP Identity Management and the back-end system, the proxy application uses a SCIM 2.0 protocol. A system can act as a proxy if it supports both read and write operations.

How a proxy system works:

1. The Identity Provisioning service exposes the back end of a supported system as a "proxy".
2. An external application (for example, SAP Identity Management) regards the proxy system as its back-end system.
3. The entities (users) exposed by the back-end system are mapped to SCIM 2.0 entities, if possible. If not possible, the SCIM standard provides a mechanism to define a new resource type with the appropriate schema. You can use the custom resource type to map the back-end entities. See: SCIM Resources
4. Finally, the external application can start sending REST web service requests to the proxy system in order to read identities from the back end of the SCIM 2.0 system.

To check the list of all supported proxy systems, see: Proxy Systems [page 1343]

Protocol

There are four types of provisioning systems based on the underlying protocol:

SCIM-based	SOAP/OData-based	LDAP-based	RFC-based
SCIM-based systems use the SCIM (System for	SOAP or OData-based systems are typically S/	LDAP-based systems use the LDAP protocol to manage	RFC-based systems use Remote Function Call (RFC)

SCIM-based	SOAP/OData-based	LDAP-based	RFC-based
Cross-domain Identity Management) standard API to manage and provision user identities.	4HANA systems which use these protocols for identity and role management within the S/4HANA environment.	and retrieve directory information.	for communication between SAP systems and between SAP and non-SAP systems.
Type: *HTTP* • Identity Authentication • Intelligent Opportunity Analyzer • Local Identity Directory • SAP Advanced Financial Closing • SAP Advanced Workflow • SAP Analytics Cloud • SAP Ariba Applications • SAP Ariba Category Management (deprecated) • SAP Ariba Central Invoice Management • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP Platform Members (Cloud Foundry) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP Concur • SAP CPQ • SAP Data Custodian • SAP Datasphere • SAP Enable Now	Type: *HTTP* • SAP BTP ABAP environment • SAP Integrated Business Planning • SAP Market Communication for Utilities • SAP Marketing Cloud • SAP S/4HANA Cloud Public Edition • SAP S/4HANA On-Premise • SAP SuccessFactors version 1	Type: *LDAP* • LDAP Server • Microsoft Active Directory	Type: *RFC* • SAP AS ABAP

SCIM-based	SOAP/OData-based	LDAP-based	RFC-based
• SAP Enterprise Portal • SAP Fieldglass • SAP Field Service Management • SAP HANA Cloud, SAP HANA Database • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Master Data Integration • SAP S/4HANA for procurement planning • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors version 2 • SAP SuccessFactors Employee Central Payroll • SAP SuccessFactors Incentive Management • SAP SuccessFactors Learning • Sales Cloud – Analytics & AI • Cloud Foundry UAA Server • Procurement Data Warehouse • SCIM System • SSH Server (Beta)			

Both Microsoft Entra ID and Google G Suite use `Type`: *HTTP*.

1.3.5 Properties

Properties hold the configuration of a provisioning system.

Properties define the connection and authentication information needed for accessing the provisioning system. They control which entities (users and groups) will be provisioned - by defining filters and unique attributes, as well as how they will be provisioned - in bulk operations or one entity at a time, with put or patch requests.

There are various types of properties depending on their usability, whether they hold mandatory or optional information, standard information in plain text or credentials in encrypted strings. They can be categorized as follows:

- Standard
- Credential
- Default
- Parameterized
- Internal

For your system provisioning goals, you can set properties in the administration console of SAP Cloud Identity Services on the *Properties* tab of the provisioning system.

Prefixes

Property names have specific prefixes that indicate the provisioning system they are applicable to. This helps you differentiate between properties designated for different systems.

- Properties starting with `<ips>` are applicable to all provisioning systems, for example `ips.failed.request.retry.attempts`.
- Properties starting with the abbreviation of a provisioning system name, such as `<s4hana.cloud>` or `<sf>`, are applicable to the respective systems—in this case, SAP S/4HANA Cloud Public Edition and SAP SuccessFactors, respectively. For example, `s4hana.cloud.support.bulk.operation` and `sf.user.filter`.
- Properties starting with `<scim>` are applicable to SCIM-based provisioning systems. To view the list of these systems, refer to System Types [page 70]. The scim-prefixed properties were used before the implementation of system-specific prefixes. Following the introduction of these prefixes, both scim and system-specific prefixes are valid.

> **Note**
>
> The scim-prefixed properties and the system-specific properties can be used interchangeably. If both are configured, Identity Provisioning will prioritize and consider the system-specific properties.

Parent topic: Concepts [page 26]

Related Information

List of Properties [page 80]
Manage Properties [page 2438]

1.3.5.1 Property Types

Properties can help you filter which entities and entity attributes are read from the source system or written to the target system. According to their usability, properties can be categorized as follows:

Standard System Properties

Each source, target, and proxy system support specific types of properties. For example:

Examples:

AS ABAP System	SAP SuccessFactors
jco.client.r3name=PSE	sf.page.size=100
jco.destination.peak_limit=10	sf.user.filter=firstName John
jco.destination.pool_capacity=5	sf.user.attributes=email

Credential Properties

The values of these properties contain sensitive information that must **not** be displayed as plain text. The default credential property name is *Password*, which can represent standard passwords, private keys, or OAuth client secrets. When you add a credential property, its value is displayed as an encrypted string. For better security, the encrypted string is always displayed as 40 characters, no matter how long your password actually is.

> **Note**
>
> Properties whose values contain sensitive information can be added only as *Credential* in the Identity Provisioning UI. The values of these properties are stored as encrypted data. They are excluded from the file during system configuration export.

Examples:

SAP HANA Database	SSH Server
hana.jdbc.db.password=**********	ssh.password=**********
	ssh.private.key=**********
	ssh.totp.secret.key=**********

> **Note**
>
> When you update the URL or the host name of an existing provisioning system, you must re-enter the values of the configured credential properties. The only exception to this are the credential properties of systems that are created with a connectivity destination.

Default System Properties

These properties depend on the particular connector type. They exist in the transformations by default. It is possible to delete some of them but this may cause a loss of provisioned data. Example:

Examples:

LDAP Server
ldap.group.object.class=groupOfNames
ldap.user.object.class=inetOrgPerson
ldap.attribute.user.mobile=mobile
ldap.group.filter=<empty>
ldap.user.filter=<empty>

Parameterized System Transformations

They use parameters taken from the system property sets. The parameters consist of a *unique key* and a *value*. Like the standard properties, they can be configured in the system's *Properties* tab, and/or in the system's destination properties (in the platform cockpit). When one parameter exists in both property sets, the system properties have priority over the system destination properties. In the system transformations, the parameter is referenced by the unique key surrounded by the percent character (*%<key>%*).

Parameters can be used within almost all JSON value parts in a transformation when the following conditions are fulfilled:

- The JSON structure is not broken. For more information see, Introducing JSON .
- The structure of the mapping transformation is not broken. For more information, see Transformations [page 388].

During the transformation evaluation, each occurrence of %<...>% is interpreted as a parameter reference and is replaced by the corresponding parameter's value as text literal. If the parameter is missing from the system configuration, that literal is *null*.

The example below shows how the mapping transformations work in case of existing parameter configuration:

System Properties	Mapping Transformation	Evaluated Transformation

`ldap.attribute.user.mail=mail`
`ldap.attribute.user.givenName=givenName`
`ldap.attribute.user.groups=memberOf`
	`{`
	`"sourcePath": "$.%ldap.attribute.user.mail%[0]",`
	`"targetPath": "$.emails[0].value",`
	`"optional": true`
	`},`
	
	`{`
	`"sourcePath": "$.%ldap.attribute.user.givenName%[0]",`
	`"targetPath": "$.name.givenName",`
	`"optional": true`
	`},`
		`{`
		`"sourcePath": "$.mail[0]",`
		`"targetPath": "$.emails[0].value",`
		`"optional": true`
		`},`
		`{`
		`"sourcePath": "$.givenName[0]",`
		`"targetPath": "$.name.givenName",`
		`"optional": true`
		`}`

You can add also optional parameters to the system properties configuration. These parameters do not appear by default at system creation and can be added on demand.

The tables below show how a system transformation including an optional parameter is evaluated:

Evaluation of Mapping Transformation with an Optional Parameter

System Properties	Mapping Transformation	Evaluated Transformation

`sac.group.prefix=SAC_GROUP`	`{`
	`"sourcePath": "$.displayName",`
	`"targetPath": "$.displayName",`
	`"functions": [`
	`{`
	`"condition": "'%sac.group.prefix%' != 'null'",`
	`"function": "concatString",`
	`"prefix": "%sac.group.prefix%"`
	`}`
	`]`
	`}`
		`{`
		`"sourcePath": "$.displayName",`
		`"targetPath": "$.displayName",`
		`"functions": [`
		`{`
		`"condition": "'SAC_GROUP' !== 'null'",`
		`// the condition is true`
		`"function": "concatString",`
		`"prefix": "%sac.group.prefix%"`
		`}`
		`]`
		`}`

System Properties	Mapping Transformation	Evaluated Transformation

No optional parameter configured	<pre>{
	  "sourcePath":
	"$.displayName",
	  "targetPath":
	"$.displayName",
	  "functions": [
	  {
	  "condition":
	"'%sac.group.prefix%' !
	== 'null'",
	  "function":
	"concatString",
	  "prefix":
	"%sac.group.prefix%"
	  }
	  ]
	}</pre>
		<pre>{
		  "sourcePath":
		"$.displayName",
		  "targetPath":
		"$.displayName",
		  "functions": [
		  {
		  "condition":
		"'null' !== 'null'",
		  // the condition
		is false
		  "function":
		"concatString",
		  "prefix":
		"%sac.group.prefix%"
		  }
		  ]
		}</pre>

> **Note**
>
> A possibility for incorrect interpretation of a %<...>% character sequences occurs if a text literal already contains more than one % characters itself.

The table below includes an example of incorrect interpretation in case of a missing parameter configuration:

System Properties	Mapping Transformation	Evaluated Transformation

No parameters configured	<pre>"condition": "$.email =~ /
	^([a-zA-Z0-9._%-]+@[a-zA-Z0-9.-]+
	\\.[a-zA-Z]{2,})$/ || $.ExternalEmail[0]
	=~ /^([a-zA-Z0-9._%-]+
	@[a-zA-Z0-9.-]+\\.[a-zA-Z]
	{2,})$/"</pre>
		<pre>"condition": "$.email =~ /
		^([a-zA-Z0-9null-]+
		@[a-zA-Z0-9.-]+\\.[a-zA-Z]
		{2,})$/"</pre>

Such cases can be avoided by extracting the parts containing % into separate parameters in the system configuration, as displayed in the table below:

System Properties	Mapping Transformation

email-regex = **/^([a-zA-Z0-9._%-]+@[a-zA-Z0-9.-]+\\.[a-zA-Z]{2,})$/**	<pre>"condition": "$.email =~ %email-regex% ||
	$.ExternalEmail[0] =~ %email-regex%"</pre>

Parameter values may contain character sequences matching a parameter reference, but such sequences are not interpreted as parameters themselves. For more information, see the table below:

System Properties	Mapping Transformation	Evaluated Transformation
parameter-A=**value-A** *parameter-B*=**value-B** **%parameter-A%**	`"constant": "%parameter-A%", .. "constant": "%parameter-B%", ..`	`"constant": "value-A", .. "constant": " value-B %parameter-A%", ..`

> ### Note
>
> Avoid using special regex characters such as `()`, `[]`, `{}`, `.`, `+`, `*`, `?`, `\`, `^`, and `|` within property values. They are evaluated in transformations - specifically in conditions involving regex strings and functions with regex parameters - and may lead to errors. For example, the following configuration will result in an error due to unfulfilled conditions:
>
> - *Property*: xsuaa.group.prefix=[XSUAA]
> - *Condition*: ('%xsuaa.group.prefix%' === 'null') || ($.displayName =~ /%xsuaa.group.prefix%.*/)

Internal Properties

> ### Note
>
> Identity Provisioning uses internal properties in various cases. Internal properties must not be used by customers.

For example:

Property Name	Value
`destinationName`	The name of the destination created in SAP BTP cockpit.

Related Information

List of Properties [page 80]
Manage Properties [page 2438]

1.3.5.2 List of Properties

On this page you can find all the available properties to use in the Identity Provisioning service. You can filter them by system type name, "All Systems", by a word or only part of it.

Name	Description	System Type
`Type`	Protocol type for making a connection **Possible values:** • *HTTP* • *LDAP* • *RFC* **System Role:** Source, Target, Proxy	All systems
URL	URL needed to make an HTTP(S) connection to an on-premise system or a cloud service **Possible value:** • When the proxy type of the HTTP connection is `Internet`: **`http(s)://<host>:<port>`** • When the proxy type of the HTTP connection is `OnPremise`: **`http://<virtualhost>:<virtualport>`** **System Role:** Source, Target, Proxy	All HTTP systems
`ProxyType`	Proxy type required for HTTP connection **Possible values:** • *Internet* • *OnPremise* **System Role:** Source, Target, Proxy	All HTTP systems

Name	Description	System Type
`Authentication`	Authentication type required for HTTP connection **Possible values:** • *NoAuthentication* • *BasicAuthentication* • *ClientCertificateAuthentication* **System Role:** Source, Target, Proxy	All HTTP systems **Note** Identity Provisioning supports certificate-based authentication for secure communication with the provisioning systems (connectors) provided by the service. Refer to the documentation of the respective systems to find out how to upload Identity Provisioning certificates on their end. For example, see How to Create Communication Users in SAP BTP ABAP Environment.
`User`	It represents: • User name – used in standard destinations • Client ID – used for access token retrieval in OAuth HTTP destinations **Possible values:** Text/numeric string **System Role:** Source, Target, Proxy	All HTTP systems
`client_id`	The OAuth Client id used for access token retrieval in case of OAuth certificate authentication. Possible values: Text/numeric string **System Role:** Source, Target, Proxy	All HTTP systems
`Password`	(Credential) It represents: • Password – used in standard destinations • Client secret key – used for access token retrieval in OAuth HTTP destinations **Possible values:** Encrypted string **System Role:** Source, Target, Proxy	All HTTP systems

Name	Description	System Type
`ips.proxy.scim.total.results.strategy`	This property determines how `totalResults` is reported in the SCIM response of the concrete IPS Proxy system. **Possible values:** • *Provided* - The `totalResults` value returned by the backend system is used as-is in the proxy response. • *Calculated* - The `totalResults` value is calculated by the proxy system based on the entities that passed the transformation condition. Default value: *Calculated* **System Role:** Proxy	All systems
`fg.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. This means, for example, that if a user attribute is modified, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Fieldglass

Name	Description	System Type
`abap.user.filter`	Filters users by a regular expression on their user-name. The regex can define any kind of search pattern. **⚠ Caution** This property is rather obsolete. For newly created systems, please use `abap.user.name.filter`. **Possible values:** For example: `abap.user.filter` = *^A.** This filter returns all user names that start with capital *A*. **System Role:** Source, Proxy	SAP Application Server ABAP
`abap.role.filter`	**⚠ Caution** This property is rather obsolete. For newly created systems, please use `abap.role.name.filter`. **Possible values:** For example: `abap.role.filter` = *^order.** This filter provisions all roles that start with *order*. **System Role:** Source, Proxy	SAP Application Server ABAP

Name	Description	System Type
`abap.user.name.filter`	Filters users by a regular expression on their username. The regex can define any kind of search pattern. This property has a higher priority over `abap.user.filter`. That means, if you set both properties in a system, the value of `abap.user.name.filter` will be used. However, if the value of `abap.user.name.filter` is empty, then `abap.user.filter`'s value will be used instead. **Note** As `abap.user.filter` is obsolete, we recommend that you use `abap.user.name.filter`. **Possible values:** For example: `abap.user.name.filter` = *^MAR.** This regex reads all user names that start with *MAR*, such as *MARK*, *MARTINA*, and so on. **System Role:** Source, Proxy	SAP Application Server ABAP

Name	Description	System Type
`abap.role.name.filter`	Filters roles by a regular expression. The regex can define any kind of search pattern. This property has a higher priority over `abap.role.filter`. That means, if you set both properties in a system, the value of `abap.role.name.filter` will be used. However, if the value of `abap.role.name.filter` is empty, then `abap.role.filter`'s value will be used instead. **Note** As `abap.role.filter` is obsolete, we recommend that you use `abap.role.name.filter`. **Possible values:** For example: `abap.role.name.filter` = *^inter.** This regex reads all roles that start with *inter*, such as *internal*, *internship*, and so on. For more information about specific search patterns, refer to SAP Note 3546855. **System Role:** Source, Proxy	SAP Application Server ABAP

Name	Description	System Type
`abap.user.page.size`	Use this property to configure the number of users to be read from SAP Application Server ABAP at once. If the property is not set, the function module `SUSR_USER_GET_DETAIL_MASS` **cannot** be used, even if it is available on the ABAP server. **Note** The property can be used only when the function module `SUSR_USER_GET_DETAIL_MASS` is exposed as an accessible resource and is present on the ABAP server. Even when these conditions are fulfilled, if the property is not set, the function module **cannot** be used. For more information, see SAP Note 3631587. **Possible values**: Default value: *100* The maximum allowed number is 100. System Role: Source, Proxy	SAP Application Server ABAP

Name	Description	System Type
`abap.role.prefix`	This property distinguishes SAP Application Server ABAP (AS ABAP) roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **ABAP_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the AS ABAP source system and will be provisioned to the target system with the following name pattern: **`ABAP_<role_name>`** . This way AS ABAP roles in the target system will be easily distinguished from roles provisioned from other applications. If the property is not set, the AS ABAP roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **ABAP_** prefix in their role name will be provisioned to AS ABAP. Roles without this prefix in their names won't be provisioned. If the property is not set, all roles will be provisioned to AS ABAP. **System Role:** Source and Target	SAP Application Server ABAP
`abap.user.membership.filter`	Filters users by a regular expression, based on their *Role* memberships in AS ABAP. The regex can define any kind of search pattern. **Possible values:** For example: `abap.user.membership.filter` = *(?i)^new.** This reads all users who have an assigned role which starts with *new*. This regex is case insensitive, which means the result can be roles starting with *new*, or *New*, or *NEW*, and so on. **System Role:** Source, Proxy	SAP Application Server ABAP

Name	Description	System Type
`ariba.applications.api.key`	(Credential) This property corresponds to the *Application key* for your SAP Ariba application. You obtain it during the creation of your application in the SAP Ariba developer portal. See: How to find your application's application key and OAuth client ID **Possible values:** Text/numeric string For example: This property corresponds to the SAP Ariba realm that your application has access to. To learn how to get it, see: *123abc123XYZ000abc123ABC012345* **System Role:** Source, Target, Proxy	SAP Ariba Applications
`ariba.applications.realm.id`	This property corresponds to the SAP Ariba realm that yourHow to find your SAP Ariba realm name? **Possible values:** Text/numeric string For example: *123abc123XYZ000abc123ABC012345* **System Role:** Source, Target, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.flatten`	This property allows or forbids reading "nested groups" (group structures) from SAP Ariba Applications. If enabled (*true*), group members of type *group* will be ignored during read in order not to be provisioned to target systems that do not support nested groups. Default value: • *Source systems:true* • *Proxy systems: false* Predefined value (during system creation): • *Source systems: true* Set it to *false* only if you are sure that the target system supports nested groups. • *Proxy systems: false* Leave the default/predefined value only if you are sure that the consuming external application (identity management system) supports nested groups. **Note** If you set this property to *true* in your proxy system, the execution of requests with parameter `membersType=group` will not be supported. **System Role:** Source, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.children.conversion`	This property allows provisioning of "nested groups" (group structures) of type authorization from SAP Ariba Applications source systems to the Identity Directory of SAP Cloud Identity Services or Identity Authentication (SCIM API version 2) target systems. When enabled (set to true), the members of a given group from SAP Ariba Applications source system will be provisioned to the target system with reversed parent-child relationship. That is, the child groups in the source system become parent groups in the target system, while the original parent group becomes a child group in the target. For more information, see the description of the `children` attribute in Groups. The property is not automatically added during system creation. **Possible values:** • *true* • *false* Default value: *false* **System Role**: Source	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.prefix`	This property distinguishes SAP Ariba Applications groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`ARIBA_APPLICATIONS_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Ariba Applications source system and will be provisioned to the target system with the following name pattern: **`ARIBA_APPLICATIONS_<GroupDisplayName>`**. This way SAP Ariba Applications groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Ariba Applications groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`ARIBA_APPLICATIONS_`** prefix in their display name will be provisioned to SAP Ariba Applications. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Ariba Applications. **System Role:** Source and Target	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.support.patch.operation`	The default value of this property is *false*. But for SAP Ariba Applications proxy systems, this property appears during creation and its predefined value is *true*. That means, when the Identity Provisioning identifies a changed entity in the back-end system, it will execute the updates as PATCH requests instead of PUT. That is, only changes will be written in SAP Ariba Applications, instead of provisioning the whole entity data. Note that only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". **Note** Removing empty groups returns 400 Bad Request instead of 200 OK. Default value: *false* Predefined value (during system creation): *true* **System Role:** Target, Proxy	SAP Ariba Applications
`ariba.applications.user.filter`	When specified, only those SAP Ariba Applications users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:** Source, Proxy	SAP Ariba Applications
`ariba.applications.group.filter`	When specified, only those SAP Ariba Applications groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.content.type`	This property makes a SAP Ariba Applications connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Ariba Applications could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Ariba Applications. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* Default value: *userName* **System Role:** Target	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Ariba Applications target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. **Possible values:** Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Ariba Applications
`ariba.applications.include.if.match.wildcard.header`	Makes the SAP Ariba Applications connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Ariba Applications system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.members.page.size`	The number of group members that SAP Ariba Applications returns per request when reading a group. When the Identity Provisioning reads a group, it compares the number of group members with the value configured for `ariba.applications.group.members.page.size`. Depending on the number of group members, you can expect the following results: • If the number of group members is equal or exceeds the configured value, and the `ariba.applications.group.members.paging.enabled` property is set to *true*, Identity Provisioning will read all group members in separate requests. For example, if a group has 6 group members and the value of the page size is set to *2*, Identity Provisioning will send 3 requests to read the group members. • If the number of group members is less than the configured value for `ariba.applications.group.members.page.size` or the property `ariba.applications.group.members.paging.enabled` is disabled, the Identity Provisioning will read all group members via one request. For example, if a group has 2 group members and the value of the page size is set to *6*, Identity Provisioning will read all group members via one request. Setting the property `ariba.applications.group.members.paging.enabled` allows you to read groups with a large number of group members. For more information, see `ariba.applications.group.members.paging.enabled`. Default value: *50* **System Role:** Source, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.group.members.paging.enabled`	This property enables paging of group members. When it is set to *true*, all groups with members count exceeding the value defined in `ariba.applications.group.members.page.size` will be read by the Identity Provisioning via subsequent requests. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **System Role:** Source, Proxy	SAP Ariba Applications
`s4hana.cloud.group.members.paging.enabled`	This property enables paging of group members. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)
`ibp.group.members.paging.enabled`	This property enables paging of group members. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)
`ibp.user.groups.paging.enabled`	This property enables paging of user groups. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`s4hana.cloud.user.groups.paging.enabled`	This property enables paging of user groups. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`ariba.applications.user.groups.page.size`	The number of user groups that SAP Ariba Application returns per request when reading a user. When the Identity Provisioning reads a user, it compares the number groups assigned with the value configured for `ariba.applications.user.groups.page.size`. Depending on the number of groups assigned to the user, you can expect the following results: • If the number of assigned groups is equal or exceeds the configured value, and the `ariba.applications.user.groups.paging.enabled` property is set to *true*, Identity Provisioning will read all user groups in separate requests. For example, if a user has 6 groups assigned and the value of the page size is set to *2*, Identity Provisioning will send 3 requests to read the user groups. • If the number of assigned groups is less than the configured value for `ariba.applications.user.groups.page.size` or the property `ariba.applications.user.groups.paging.enabled` is disabled, the Identity Provisioning will read all user groups via one request. For example, if a user has 2 groups assigned and the value of the page size is set to *6*, Identity Provisioning will read all user groups via one request. Setting the property `ariba.applications.user.groups.paging.enabled` allows you to read users with a large number of groups assigned. For more information, see `ariba.applications.user.groups.paging.enabled`. Default value: *50* **System Role:** Source, Proxy	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.user.groups.paging.enabled`	This property enables paging of user's groups. This maximum value is specified by the property `ariba.applications.group.members.page.size`. To read a user with *'groups'* attribute over the configured value, set `ariba.applications.user.groups.paging.enabled` to *true*. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **System Role:** Source, Proxy	SAP Ariba Applications
`c4c.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`c4c.api.version`	This property defines the API version that the API of your SAP Sales Cloud and SAP Service Cloud system uses. **Possible values:** • *1* • *2* • *3* • *4* By default, Identity Provisioning uses version *4*, which means - SCIM 2.0 based API. **System Role:** Source, Target, Proxy	SAP Sales Cloud and SAP Service Cloud
`btp.cf.pm.origin`	The value of this property is the origin key of your SAP Cloud Identity Services tenant. You can find it in the SAP BTP cockpit. Go to your SAP BTP subaccount, choose *Trust Configuration* and see the value under *Origin Key* for the relevant *Custom Identity Provider for Platform Users*. The value of this property is a string, which always ends with the suffix *-platform*. It will be used as the *origin* attribute in the system transformation. **Possible values:** Text/numeric string **System Role:** Source, Target, Proxy	SAP BTP Platform Members (Cloud Foundry)

Name	Description	System Type
`btp.cf.pm.landscape`	Enter the *technical key* or the *host name* of the landscape in which your multi-environment subaccount with enabled Cloud Foundry environment is located. The techical key is available only for the SAP BTP Cloud Foundry regions. For more information, see Regions and API Endpoints Available for the Cloud Foundry Environment. Please note that when the technical key contains an extension index, the correct value is displayed in the *API Endpoint* column instead of the *Technical Key* column of the table. This is an example of a *technical key*: **`cf-eu10-002`**, corresponding to the API endpoint `api.cf.eu10-002.hana.ondemand.com` and host name `cf.eu10-002.hana.ondemand.com` The host name of the landscape can be found by looking up the *API Endpoint* field in the *Overview* tab of your *Cloud Foundry Environment* on subaccount level of the SAP BTP cockpit. The API endpoint has the following format: `https://api.<landscape-hostname>` **Possible values:** Text/numeric string **System Role:** Source, Target, Proxy	SAP BTP Platform Members (Cloud Foundry)

Name	Description	System Type
`btp.cf.pm.group.prefix`	This property distinguishes SAP BTP Platform Members (Cloud Foundry) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`BTP_CF_PM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP BTP Platform Members (Cloud Foundry) source system and will be provisioned to the target system with the following name pattern: **`BTP_CF_PM_<GroupDisplayName>`**. This way SAP BTP Platform Members (Cloud Foundry) groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP BTP Platform Members (Cloud Foundry) groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`BTP_CF_PM_`** prefix in their display name will be provisioned to SAP BTP Platform Members (Cloud Foundry). Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP BTP Platform Members (Cloud Foundry). **System Role:** Source and Target	SAP BTP Platform Members (Cloud Foundry)
`btp.cf.pm.user.filter`	When specified, only those SAP BTP Platform Members (Cloud Foundry) users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:**Source, Proxy	SAP BTP Platform Members (Cloud Foundry)

Name	Description	System Type
`c4c.custom.namespace.<prefix>`	**Note** Only relevant to API **v.2**. The Identity Provisioning service uses a single predefined namespace for all attributes. However, you can provision entities by defining your own (custom) namespaces for some attributes. For this purpose, you have to: 1. Specify a namespace using this property. 2. Set the custom namespace in the JSON transformation. For more information, see: SAP Sales Cloud and SAP Service Cloud [page 1211] The value of this property is the namespace URI. For **<prefix>**, enter the prefix of the custom XML namespace (for example, *a123*). Example for setting up the whole property: *c4c.custom.namespace.a123=http://sap.com/xi/AP/CustomerExtension/ABC/A123XX* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud
`cbc.user.filter`	When specified, only those SAP Central Business Configuration users matching the filter expression will be read. **Note** For source systems only: Using this property makes sense only if you have set the *"ignore": true* statement to *false*. **Possible values:** For example: *name.familyName eq "Smith" and addresses.country eq "US"* **System Role:** Source, Proxy	SAP Central Business Configuration

Name	Description	System Type
`cbc.group.filter`	When specified, only those SAP Central Business Configuration groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1" or "Employees2020"* **System Role:** Source, Proxy	SAP Central Business Configuration
`cbc.group.prefix`	This property distinguishes SAP Central Business Configuration groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CBC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Central Business Configuration source system and will be provisioned to the target system with the following name pattern: **`CBC_<GroupDisplayName>`**. This way SAP Central Business Configuration groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Central Business Configuration groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`CBC_`** prefix in their display name will be provisioned to SAP Central Business Configuration. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Central Business Configuration. **System Role:** Source and Target	SAP Central Business Configuration

Name	Description	System Type
`dc.group.filter`	This property filters groups by display name or externalId. When specified, only those groups matching the filter expression will be read. **Possible values:** • *SAP_Data_Custodian_Auditor* • *SAP_Data_Custodian_Service_Admin* • *SAP_Data_Custodian_Key_Admin* • *SAP_Data_Custodian_Key_User* For example: *displayName eq "SAP_Data_Custodian_Auditor"* **System Role:** Source, Proxy	SAP Data Custodian
`dc.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `dc.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Data Custodian
`dc.user.filter`	When specified, only those SAP Data Custodian users matching the filter expression will be read. You can filter users by *userName*, *displayName* or *externalId*. **Possible values:** For example: *userName eq "Smith.J"* **System Role:** Source, Proxy	SAP Data Custodian

Name	Description	System Type
`dc.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system via this filter, the creation will fail. **Default behavior**: This property is missing during system creation. Its default value is *userName*. This means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. Default value: *userName* **System Role:** Target	SAP Data Custodian
`dc.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP Data Custodian

Name	Description	System Type
`dc.include.if.match.wildcard.header`	Makes the SAP Data Custodian connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Data Custodian system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Data Custodian

Name	Description	System Type
`dc.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Data Custodian

Name	Description	System Type
`dc.group.prefix`	This property distinguishes SAP Data Custodian groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`DC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Data Custodian source system and will be provisioned to the target system with the following name pattern: **`DC_<GroupDisplayName>`**. This way SAP Data Custodian groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Data Custodian groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`DC_`** prefix in their display name will be provisioned to SAP Data Custodian. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Data Custodian. **System Role:** Source, Target	SAP Data Custodian
`ds.user.filter`	When specified, only those SAP Datasphere users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:**Source, Proxy	SAP Datasphere

Name	Description	System Type
`ds.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Datasphere. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* Default value: *userName* **System Role:** Target	SAP Datasphere

Name	Description	System Type
`ds.include.if.match.wildcard.header`	This property makes the SAP Datasphere connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. The header could be used by an SAP Datasphere system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Datasphere

Name	Description	System Type
`ds.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a **PATCH** request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. • If set to *false*, **PUT** operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Datasphere

Name	Description	System Type
`ds.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. Default value: *30* **Note** The value must not exceed the number of entities defined by the SAP Datasphere system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Payload Too Large*). **System Role:** Target	SAP Datasphere
`ds.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. The property is automatically added in the system, with default value: *enabled*. **Possible values:** • *enabled* • *disabled* Default value: *enabled* **Note** If the property is missing, its default value is **disabled**. **System Role:** Target, Proxy	SAP Datasphere

Name	Description	System Type
`hcp.application.names`	Enter a comma-separated list of application names. That could be applications deployed on your account, or applications for which your account has subscribed. The property returns the roles assigned to these applications. **Possible values:** Use the following format (no spaces): *<app_name1>,<app_name2>,<provider_subaccount>:<provider_app>* For example: *myapp1,myapp2,provider1:app123,provider2:cloud789,mynewapp* **⚠ Caution** You must not leave this property with an empty value. **System Role:** Source	SAP BTP Java/HTML5 apps (Neo)
`hcp.read.group.roles`	If you set this property to *true*, the Identity Provisioning will read the following additional attributes for a SAP Business Technology Platform group: - Application roles - Group mappings, defined by your identity provider **⚠ Restriction** This property is applicable only if SAP Business Technology Platform and the external SCIM-based system belong to one and the same region. **Possible values:** - *true* - *false* Default value: *false* **System Role:** Proxy	SAP BTP Java/HTML5 apps (Neo)

Name	Description	System Type
`hcp.group.prefix`	This property distinguishes groups from Java/HTML5 applications running on SAP BTP, Neo environment by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`HCP_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Business Technology Platform source system and will be provisioned to the target system with the following name pattern: **`HCP_<GroupDisplayName>`**. This way groups from Java/HTML5 applications running on SAP BTP, Neo environment in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the groups from Java/HTML5 applications running on SAP BTP, Neo environment will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`HCP_`** prefix in their display name will be provisioned to SAP Business Technology Platform. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Business Technology Platform. **System Role:** Source and Target	SAP BTP Java/HTML5 apps (Neo)

Name	Description	System Type
`hcp.patch.response.with.resource`	Use this property when you execute hybrid scenarios with SAP Business Technology Platform (Neo) as a SCIM proxy system, and you update an entity (mostly relevant to groups, like when you change the members of a group) via a PATCH request. If you set this property to *true*, the successful **PATCH** request will return a response code 200 (*OK*) back to the consumer client application with a payload body containing the updated attributes of the relevant group. If you don't specify the property (or it's set to *false*), the successful **PATCH** request will return a response code 204 (*No Content*) indicating successful group update but with no payload body. For more information, see: SCIM 2.0: Modifying with PATCH . **Possible values:** • *true* • *false* Default value: *false* **System Role:** Proxy	SAP BTP Java/HTML5 apps (Neo)
`ia.group.filter`	When specified, only those SAP Intelligent Agriculture groups matching the filter expression will be read. **Possible values:** • *intagri_Data_Scientist* • *intagri_Farm_Manager* • *intagri_Operator* • *intagri_Operations_Planner* • *intagri_Master_Data_Manager* • *intagri_Administrator* For example: *displayName eq "intagri_Master_Data_Manager"* **System Role:** Source, Proxy	SAP Intelligent Agriculture

Name	Description	System Type
`ia.user.filter`	When specified, only those SAP Intelligent Agriculture users matching the filter expression will be read. Supported operators: `eq` (equal), `ne` (not equal), `sw` (starts with), `ew` (ends with) and `co` (contains) **Possible values:** For example: *userName eq "Smith.J"* *emails eq "julie.armstrong@example.com"* **System Role:** Source, Proxy	SAP Intelligent Agriculture
`ia.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is *displayName*. Currently, it is the only unique attribute that is supported. When set, you can expect the following behavior: • If a group with the given *displayName* is found in the target system, the group that you try to provision will overwrite the existing one. • If a group with the given *displayName* is not found in the target system, the group that you try to provision will not be created in the target system. If the property is not specified, the search is done by the default attribute: `displayName` **System Role:** Target	SAP Intelligent Agriculture

Name	Description	System Type
`ia.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system via this filter, the creation will fail. **Default behavior**: This property is missing during system creation. Its default value is *userName* . This means, if the service finds an existing user by a *userName* , it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. **Possible values:** • *userUuid* • *emails* • *userName* • *externalId* Default value: *userName* **System Role:** Target	SAP Intelligent Agriculture

Name	Description	System Type
`ia.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Intelligent Agriculture

Name	Description	System Type
`ia.group.prefix`	This property distinguishes SAP Intelligent Agriculture groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IA_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Intelligent Agriculture source system and will be provisioned to the target system with the following name pattern: **`IA_<GroupDisplayName>`**. This way SAP Intelligent Agriculture groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Intelligent Agriculture groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`IA_`** prefix in their display name will be provisioned to SAP Intelligent Agriculture. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Intelligent Agriculture. **System Role:** Source, Target	SAP Intelligent Agriculture
`ia.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Intelligent Agriculture system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Intelligent Agriculture

Name	Description	System Type
`idds.group.filter`	This property filters groups by display name. You can set a single display name or multiple ones as filter criteria. If you enter multiple display names (using **OR** operator), the filter will search for any of them. Value pattern (single): *displayName eq "<group_name>"* Value pattern (multiple): *displayName eq "<group_name1>" or displayName eq "<group_name2>"* **Possible values:** For example: • Single: *displayName eq "FellowshipTeam1"* • Multiple: *displayName eq "FellowshipTeam1" or displayName eq "JuniorTest3"* **System Role:** Source, Proxy	Local Identity Directory

Name	Description	System Type
`idds.user.filter`	This property filters users by particular attributes. You can set a single attribute or multiple ones as search criteria. Value pattern (single): *<user_attribute> eq "<value>"* Value pattern (multiple): *<user_attribute1> eq "<value1>" and/or <user_attribute2> eq "<value2>"* **Possible values:** For example: • Single: *userName eq "Sebastian"* • Multiple (with **OR**): *userName eq "Sebastian" or addresses.country eq "France"* • Multiple (with **AND**): *userName eq "Sebastian" and addresses.country eq "France"* • Multiple (with brackets): *userName eq "Sebastian" or (addresses.country eq "France" and emails.value eq "sebastian123@mail.com")* • Multiple (enterprise attributes): *urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:department eq "Dev" and urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:organization eq "Technology"* **System Role:** Source, Proxy	Local Identity Directory
`idds.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 20 000. To read more than 20 000 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	Local Identity Directory

Name	Description	System Type
`idds.user.groups.paging.enabled`	This property enables paging of user's groups. The maximum number of user's groups returned per request is 1 000. To read more than 1 000 user's groups, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *false* **System Role:** Source, Proxy	Local Identity Directory
`idds.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	Local Identity Directory

Name	Description	System Type
`idds.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In such cases, the existing group only needs to be updated. This property defines the unique attribute(s) by which the existing group will be searched and resolved. The default value is *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']*. When set, you can expect the following behavior: • If a group with the given *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* is found in the target system, the group that you try to provision will overwrite the existing one. • If a group with the given *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* is not found in the target system, the group that you try to provision will not be created in the target system. In scenarios where groups are provisioned from SAP Integrated Business Planning version 2 and SAP S/4HANA Cloud Public Edition version 3, the uniqueness of the group is resolved by a combination of three attributes: *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],* *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],* *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']* For the conflict to be resolved, an existing group must match all three attributes. If the property is not specified, the search is done by the default attribute: *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* **System Role:** Target	Local Identity Directory

Name	Description	System Type
`idds.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	Local Identity Directory

Name	Description	System Type
`idds.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with "scope": "createEntity", such as: `{ "constant":true, "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']", "scope":"createEntity" }` • If set to *false*, Identity Provisioning sends a PUT request to the user or group resource in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Users and groups can be updated in the target system in various cases, such as: • In the source system, some user or group attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users or groups not to be read anymore. • A user or a group is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**.	Local Identity Directory

Name	Description	System Type
	Possible values: • *true* • *false* Default value: *false* **System Role:** Target, Proxy	

Name	Description	System Type

`idds.user.automatic.conflict.resolution`	Controls whether automatic conflict resolution is switched on or off in Local Identity Directory (target system) when provisioning is triggered from source systems containing different users with the same user identifiers (IDs).
	
	For example, when SAP SuccessFactors and SAP SuccessFactors Learning are configured as source systems for provisioning users to Local Identity Directory, it could happen that different SAP SuccessFactors and SAP SuccessFactors Learning users have the same user IDs. In this case, when the first user is created in Local Identity Directory, after triggering a provisioning job, the second (conflicting) user will either overwrite the already existing one (automatic conflict resolution is switched on) or will fail and won't be created (automatic conflict resolution is switched off).
	
	To control this behavior, you can use the `idds.user.automatic.conflict.resolution` property in the target Local Identity Directory system. This property is not added by default.
	
	Possible values:
	
	• *true* - If the property is set to true, or is not set at all, the automatic conflict resolution is switched on. This means that Identity Provisioning takes into account the unique attribute(s) defined on the `idds.user.unique.attribute` property and tries to find an already existing user in Local Identity Directory matching these attributes.
	  ◦ If a user is found, the provisioning of a new (conflicting) user is resolved as follows: the conflicting user overwrites the existing one.
	  ◦ If a user is not found, the provisioning of a conflicting user fails, and it is not created in Local Identity Directory.
	• *false* - If the property is set to false, the automatic conflict resolution is switched off. This means that Identity
		Local Identity Directory

Name	Description	System Type
	Provisioning does not take into account the unique attribute(s) defined on the `idds.user.unique.attribute` property and fails the provisioning of a conflicting user. This user is not created in Local Identity Directory and does not overwrite the existing one. In the Job Log, an error code `409, uniqueness` will be displayed. Default value: *true* **System Role:** Target	

Name	Description	System Type
`idds.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. **If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find a user on the target system via this filter, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *phoneNumbers[0].value*. If the service finds an existing user with such *phoneNumber*, it updates this user with the data of the conflicting one. If a user with such *phoneNumber* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, phoneNumbers[0].value*. If the service finds an existing user with both these *userName* and *phoneNumber*, it updates this user with the data of the conflicting one. If such a user is not found, that	Local Identity Directory

Name	Description	System Type
	means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, emails[0].value, phoneNumbers[0].value*. If the service finds an existing user with these *userName*, *email* and *phoneNumber*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *phoneNumbers[0].value* • *userName, phoneNumbers[0].value* • *userName, emails[0].value, phoneNumbers[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	

Name	Description	System Type
`idds.user.update.instead.delete`	`PATCH` request in Local Identity Directory target system and to preserve the user record instead of deleting it. This behavior is supported only when the scope of the attribute is set to **deleteEntity**. In addition to configuring this property, you also need to adapt the write transformation. For example, if you want to disable a user account in Local Identity Directory, you need to do the following: 1. Set `idds.user.update.instead.delete`=*true* 2. Adapt the write transformation as follows: `{ "user":{ "mappings":[{ "constant":"urn:ietf:params:scim:api:messages:2.0:PatchOp", "targetPath":"$.schemas[0]", "scope":"deleteEntity" }, { "constant":"replace", "targetPath":"$.Operations[0].op", "scope":"deleteEntity" }, { "constant":"active", "targetPath":"$.Operations[0].path", "scope":"deleteEntity" }, { "constant":false, "targetPath":"$.Operations[0].value", "scope":"deleteEntity" }, ...`	Local Identity Directory

Name	Description	System Type
	In this case, the PATCH operation will replace *true* with *false* as the value of the `active` user attribute. As a result, when the PATCH operation is executed, the user record in the target system will no longer be managed by Identity Provisioning as it is considered deleted. For more information, see: Transformation Expressions [page 391] → *Scope* → *deleteEntity* **Possible values:** • *true* • *false* Default value: *false* When the property is set to *true*, adapt the write transformation with the attribute name and the attribute value you want to update: `{ "user":{ "mappings":[{ "constant":"urn:ietf:params:scim:api:messages:2.0:PatchOp", "targetPath":"$.schemas[0]", "scope":"deleteEntity" }, { "constant":"replace", "targetPath":"$.Operations[0].op", "scope":"deleteEntity" }, { "constant":"<attribute_name>", "targetPath":"$.Operations[0].path", "scope":"deleteEntity" }, { "constant":<attribute_value>, "targetPath":"$.Operations[0].value",`	

Name	Description	System Type

	`"scope":"deleteEntity"`
	`},`
	`...`
	
	System Role: Target	

`ips.date.variable.format`	This is a default property that the Identity Provisioning UI automatically adds to the configuration of every newly created system. The property allows you to change the default date format to another, more suitable for your scenario. See also: Transformation Variables [page 490]. Default value: *yyyy-MM-dd HH:mm:ss.SSS* **System Role:** Source, Target, Proxy	All systems
`ips.delete.existedbefore.entities`	**Use case:** An entity exists on the target system, and then a provisioning job reads the same entity from a source system and updates it on the target. If later on you delete this entity from the source system, the next provisioning job will recognize it as a "previously existed one" and will **not delete** it from the target. If you want such *recognized* entities to be deleted from the target as well, open the relevant target system and set this property to **true**. For more information, see Manage Deleted Entities [page 2463]. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	All systems

Name	Description	System Type
`ips.overwrite.existedbefore.assignments`	This property defines whether or not the Identity Provisioning service to overwrite user/group assignments that have existed in the target system before you start provisioning entities to that system. **Example:** Let's say there is a group in the target system that contains some assignments (users and subgroups). In the source system there is a matching group, which contains different assignments. • If you start a provisioning job without setting this property (by default, it's *true*), all assignments from the source group will overwrite the ones from the target group. • If you set the property to *false*, all existing assignments will be kept in the target system group, and the new ones will just be added. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Target	SAP Application Server ABAP
`ips.failed.request.retry.attempts`	If an entity operation fails due to an occurred exception (rate limit, bad gateway, missing authorization, or timeout), you can specify a number of retries for this operation. Use this property to set the number of retries. > **Note** > Rate limit is the controlled rate of requests sent to a system. Some systems implement rate limit to avoid overloading and performance issues. **Possible values:** Default value: *2* Maximum value: *3* **System Role:** Source, Target, Proxy	All systems > **Note** > For more information about the cases in which the retry is supported, see Handle Failed Operations [page 2482].

Name	Description	System Type
`ips.failed.request.retry.attempts.interval`	Specify a time interval (in seconds) between the retries, in case an operation fails due to an occurred exception. This property is related to `ips.failed.request.retry.attempts`. **Possible values:** Default value: *30* Maximum value: *60* **Note** Following an HTTP 502 Bad Gateway server error, the time interval for SAP BTP XS Advanced UAA (Cloud Foundry) and SAP Sales Cloud and SAP Service Cloud must not exceed 50 (seconds). **System Role:** Source, Target, Proxy	All systems **Note** For more information about the cases in which the retry is supported, see Handle Failed Operations [page 2482].

Name	Description	System Type
`ips.job.notification.repeat.on.failure`	If you have activated notifications for a source system and a provisioning job fails, you'll receive notification e-mails with subject *Provisioning Finished with Error*. You can also receive an e-mail if you manually stop a running job. With property `ips.job.notification.repeat.on.failure`, you can control the frequency of the received notifications. • If you set the property to *true*, you will receive notification e-mails every time a job fails. • If you want to stop or control the notification frequency, set the property to *false* (default value). This property has a higher priority than `ips.job.notification.ignored.consecutive.failures`. See also: Manage Job Notifications [page 3018]. **Possible values:** • *true* • *false* Default value: *false*. That means, when a job fails, only one notification e-mail will be sent. **System Role:** Source	All systems

Name	Description	System Type
`ips.job.notification.ignored.consecutive.failures`	If you have activated notifications for a source system and a provisioning job fails, you'll receive notification e-mails with subject *Provisioning Finished with Error*. You can also receive an e-mail if you manually stop a running job. With property `ips.job.notification.ignored.consecutive.failures`, you can control the number of the received consecutive notifications. > **Note** > Property `ips.job.notification.repeat.on.failure` must be set to *false* or not specified at all. **Example:** If you set `ips.job.notification.ignored.consecutive.failures` = *3* and the job is constantly failing, the first three times you'll not receive a notification. On the fourth job fail, you will receive one notification e-mail. No subsequent e-mails will be sent by the service until the first successful run of the job. See also: Manage Job Notifications [page 3018]. Default value: *0*. That means, a notification e-mail will be sent after the first job fail. **System Role:** Source	All systems

Name	Description	System Type
`ips.job.notification.skip.intermediate.notifications`	If you have activated notifications for a source system, and an entity fails during the provisioning job, you'll receive one notification e-mail with subject *Provisioning Running with Error*. Property `ips.job.notification.skip.intermediate.notifications` controls whether you will receive a notification or not. • If the property is set to *true*, no notifications will be sent. • If the property is not specified or is set to *false* (default), you'll receive one notification e-mail. No subsequent e-mails will be sent by the service until the first successful run of the job. See also: Manage Job Notifications [page 3018]. **Possible values:** • *true* • *false* Default value: *false*. That means, after the first failed entity, a notification e-mail will be sent. **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.failed.entity.content`	If a provisioning job repeatedly fails and you need problem investigation, you can enable logging and tracing for the personal and sensitive data of your provisioned entities. To do this, set the property to *true* to enable logging and tracing for the personal and sensitive data of your provisioned entities by the next executed job. After the job has finished, the property is automatically set to *false*. If the property is not set, in the logs you see: `content = <hidden content>` To learn more about personal and sensitive data, see: • Glossary for Data Protection and Privacy • Customer Data → **Data Storage Security** **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.skipped.entity.content`	If a provisioning job results in skipping entities from source or target systems, you can view the details for each skipped user and group. To do this, set the property to *true* to enable logging and tracing for the personal and sensitive data of your provisioned entities by the next executed job. After the job has finished, the property is automatically set to *false*. If the property is not set, in the logs you see: `content = <hidden content>` To learn more about personal and sensitive data, see: • Glossary for Data Protection and Privacy • Customer Data → **Data Storage Security** **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.created.entity.content`	If a provisioning job results in created entities in target or proxy systems, you can view the details for each created user and group. To do this, set the property to *true* to enable logging and tracing for the personal and sensitive data of your provisioned entities by the next executed job. After the job has finished, the property is automatically set to *false*. If the property is not set, in the logs you see: `content = <hidden content>` To learn more about personal and sensitive data, see: • Glossary for Data Protection and Privacy • Customer Data → **Data Storage Security** **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.updated.entity.content`	If a provisioning job results in updated entities in target or proxy systems, you can view the details for each updated user and group. To do this, set the property to *true* to enable logging and tracing for the personal and sensitive data of your provisioned entities by the next executed job. After the job has finished, the property is automatically set to *false*. If the property is not set, in the logs you see: `content = <hidden content>` To learn more about personal and sensitive data, see: • Glossary for Data Protection and Privacy • Customer Data → **Data Storage Security** **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source	All systems
`ips.trace.skipped.entity`	This property allows you to download and view the details of all skipped entities for a given job in a `zip` archive. For more information, see Manage Provisioning Job Logs [page 3010] **Possible values:** • *true* - The downloaded `zip` file contains all skipped entities for the given job, the systems they are skipped from, the reason behind this, as well as the content of the entities (if `ips.trace.skipped.entity.content` is set to **`true`**). • *false* - The downloaded `zip` file is empty. Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.deleted.entity`	This property allows you to download and view the details of all deleted entities for a given job in a `zip` archive. For more information, see Manage Provisioning Job Logs [page 3010] **Possible values:** • *true* - The downloaded `zip` file contains all deleted entities for the given job and the systems from which they are deleted. • *false* - The downloaded `zip` file is empty. Default value: *false* **System Role:** Source	All systems
`ips.trace.created.entity`	This property allows you to download and view the details of all created entities for a given job in a `zip` archive. For more information, see Manage Provisioning Job Logs [page 3010] **Possible values:** • *true* - The downloaded `zip` file contains all created entities for the given job, the systems in which they are created, as well as the content of the entities (if `ips.trace.created.entity.content` is set to **`true`**). • *false* - The downloaded `zip` file is empty. Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.trace.updated.entity`	This property allows you to download and view the details of all updated entities for a given job in a `zip` archive. For more information, see Manage Provisioning Job Logs [page 3010] **Possible values:** • *true* - The downloaded `zip` file contains all updated entities for the given job, the systems in which they are updated, as well as the content of the entities (if `ips.trace.updated.entity.content` is set to **`true`**). • *false* - The downloaded `zip` file is empty. Default value: *false* **System Role:** Source	All systems

Name	Description	System Type
`ips.http.header.<header_name>`	Use this property to pass additional information with the HTTP requests. The provisioning system may override your custom HTTP headers, if specific header settings are implemented in the system. **Possible values:** • Example for an authorization header: `ips.http.header.authorization` = *Basic VDAwdfhjgHGSzmfnNA==* > **Note** > If you provide credentials for the provisioning system, this property will not take effect. Its value (token) will be overridden by the token generated by the system implementation. • Example for a header that allows you to control whether teams (meaning groups) should keep their role assignments in SAP Analytics Cloud (SCIM API version 1) upon update: `ips.http.header.x-ignore-roles-if-missing` Possible values: • *true* - Teams will keep their role assignments when no roles are provisioned. • *false* - Teams will lose their role assignments when no roles are provisioned. This is the default value. For more information, see SAP note 3092730. In SAP Analytics Cloud (SCIM API version 2), this behavior is managed by `sac.support.patch.operation` property. **System Role:** Source, Target, Proxy	All HTTP systems

Name	Description	System Type
`ips.delta.read`	If this property is enabled,the provisioning job does not retrieve the entire amount of source system data but only the last changed entities. This property can be used in combination with `ips.full.read.force.count`. For more information refer to the description of the property or Manage Full and Delta Read [page 2459]. **Possible values:** • *enabled* • *disabled* **System Role:** Source	• Identity Authentication • Intelligent Opportunity Analyzer • Local Identity Directory • Microsoft Active Directory • SAP Advanced Financial Closing • SAP Advanced Workflow • SAP Central Business Configuration • SAP Concur • SAP CPQ • SAP Data Custodian • SAP Enterprise Portal • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Intelligent Agriculture • SAP Signavio Process Transformation Suite • SAP SuccessFactors • SAP SuccessFactors Employee Central Payroll • SAP SuccessFactors Learning • SCIM System • SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`ips.full.read.force.count`	If your system (connector) works in *delta read* mode, it's recommended to enforce full reads from time to time. To achieve this, set this property to an integer number. This property is used in combination with `ips.delta.read`. When the provisioning system works in *delta read* mode, the Identity Provisioning triggers a full read job after executing the defined number of delta read jobs. If the full read job finishes successfully, the system switches to *delta read* mode. If it fails, the system continues triggering full read jobs until one finishes successfully. **Possible values:** For example: *10* This value results in alternating full reads after every 10 delta reads are performed. In case the property is not set, only delta read jobs will be executed. For more information, see Manage Full and Delta Read [page 2459]. **System Role:** Source	• Identity Authentication • Local Identity Directory • SAP Advanced Financial Closing • SAP Advanced Workflow • SAP Analytics Cloud • SAP Ariba Applications • SAP BTP ABAP environment • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP SuccessFactors Incentive Management • SAP Concur • SAP CPQ • SAP Data Custodian • SAP Enetrprise Portal • SAP Fieldglass • SAP Field Service Management • SAP Integrated Business Planning • SAP Jam Collaboration • SAP Market Communication for Utilities • SAP Marketing Cloud • SAP Master Data Integration • SAP S/4HANA Cloud Public Edition • SAP S/4HANA for procurement planning • SAP S/4HANA On-Premise • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors • SAP SuccessFactors Learning • Sales Cloud – Analytics & AI • Cloud Foundry UAA server • Google G Suite • LDAP Server • Microsoft Active Directory • Microsoft Entra ID • SCIM System

Name	Description	System Type
`ips.application.id`	This property holds the value of the *Application ID* of the application, created in the SAP Cloud Identity Services tenant. Its main purpose is to show that a group is associated with a particular application. This is an optional property set by the customer. The *application ID* is the identifier of an application configured in SAP Cloud Identity Services - Identity Authentication that corresponds to a particular source system configured in the administration console for SAP Cloud Identity Services. It is used to distinguish groups provisioned from various source systems to the Identity Directory of SAP Cloud Identity Services. When the property is set, the groups are provisioned with their *applicationId* attribute which is internally mapped to the name of the corresponding application. As a result, the name of the associated application with the group is displayed in the *Application Name* field under *Users&Authorizations* > *Groups*. **System Role:** Source, Target	• Identity Authentication (SCIM API version 2) • Local Identity Directory • Microsoft Entra ID • SAP Advanced Financial Closing • SAP Analytics Cloud • SAP Application Server ABAP • SAP Ariba Applications • SAP Ariba Central Invoice Management • SAP BTP ABAP environment • SAP BTP Account Members (Neo) • SAP Build Work Zone, advanced edition • SAP BTP Platform Members (Cloud Foundry) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Central Business Configuration • SAP Commerce Cloud • SAP Concur • SAP CPQ • SAP Data Custodian • SAP Enable Now • SAP Fieldglass • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Integrated Business Planning • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Marketing Cloud • SAP Market Communication for Utilities • SAP Sales Cloud and SAP Service Cloud • SAP Signavio Process Transformation Suite • SAP S/4 HANA Cloud • SAP SuccessFactors Employee Central Payroll • SAP Revenue Growth Management • Cloud Foundry UAA Server • Procurement Data Warehouse

Name	Description	System Type
`OAuth2TokenServiceURL`	If you need to make OAuth authentication to the system, enter the URL to the access token provider service. **Possible values:** Access token URL **System Role:** Source, Target, Proxy	• Cloud Foundry UAA Server • Google G Suite • Intelligent Opportunity Analyzer • Microsoft Entra ID • Sales Cloud – Analytics & AI • SAP Analytics Cloud • SAP Ariba Applications • SAP Ariba Category Management • SAP Ariba Central Invoice Management • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP CPQ • SAP Data Custodian • SAP Datasphere • SAP Fieldglass • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Master Data Integration • SAP Advanced Financial Closing • Procurement Data Warehouse • SAP Sales Cloud and SAP Service Cloud • SAP S/4HANA for procurement planning • SCIM System

Name	Description	System Type
`OAuth2TokenScope`	If your backend system is OAuth protected and requires an access token with scope, use this property to specify the scope. It defines the token's level of access to protected resources. This is an optional property. Providing a value only makes sense if the backend system and its trusted OAuth server requires it. For more information, see OAuth Scopes . OAuth does not define particular values for scopes as they are system-specific. Both single and multiple scope values are accepted. When using multiple scopes, space is the standard delimiter, as defined in the OAuth 2.0 Authorization Framework . **Possible values**: • Example value of Google G Suite OAuth single scope: **`https://www.googleapis.com/auth/admin.directory.user`**. Although Google G Suite OAuth scopes look like URLs, they are not web pages. They are access token permissions. • Example value of multiple space-delimited scopes: **`read write delete`** **System Role:** Source, Target, Proxy	• Cloud Foundry UAA Server • Google G Suite • Microsoft Entra ID • Sales Cloud – Analytics & AI • SAP Analytics Cloud • SAP Ariba Applications • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP Data Custodian • SAP Fieldglass • SAP Jam Collaboration • SAP Master Data Integration • SAP Advanced Financial Closing • SAP S/4HANA for procurement planning • SCIM System
`jco.client.user`	Enter the user for AS ABAP. **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.client.passwd`	(Credential) Enter the password for the AS ABAP user. **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.client.ashost`	Enter the virtual host entry that you have configured in the Cloud connector → *Access Control* configuration. **Possible values:** For example: *abapserver.hana.cloud* **System Role:** Source, Target, Proxy	SAP Application Server ABAP

Name	Description	System Type
`jco.client.client`	Enter the client to be used in the ABAP system. Valid format is a three-digit number. **Possible values:** For example: *001* **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.client.r3name`	Enter the three-character system ID of the ABAP system to be addressed. **Possible values:** For example: *WPE* **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.client.sysnr`	Enter the "system number" of the ABAP system. **Possible values:** For example: *42* **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.destination.proxy_type`	Defines the proxy type of the connection you need to provide for your ABAP system. The proxy type *OnPremise* requires the Cloud Connector to access resources within your on-premise network. **Possible values:***OnPremise* **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.destination.peak_limit`	Represents the maximum number of active connections that can simultaneously be created for a destination. **Possible values:** For example: *10* **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`jco.destination.pool_capacity`	Represents the maximum number of idle connections kept open by the destination. **Possible values:** For example: *5* **System Role:** Source, Target, Proxy	SAP Application Server ABAP

Name	Description	System Type
`jco.client.mshost`	Represents the message server host to be used. **System Role:** Source, Target, Proxy	SAP Application Server ABAP
`X-ConsumerKey`	(Credential) Enter the Concur access token needed for the connection. **System Role:** Target, Proxy	SAP Concur
`jwt.subject`	Enter the Google G Suite user on behalf of which the Google Directory API is called. **System Role:** Target, Proxy	Google G Suite
`jwt.scope`	Enter space-separated Google Directory API authorization scopes. **System Role:** Target, Proxy	Google G Suite
`ldap.url`	URL needed to make an LDAP connection to an on-premise system or a cloud service **Possible values:** `ldap://<host><port>` **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.proxyType`	Proxy type for the LDAP connection **Possible values:** *OnPremise* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.authentication`	Authentication type for the LDAP connection **Possible values:** *BasicAuthentication* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.user`	User name for the LDAP Server **Possible values:** Text/numeric string **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.password`	(Credential) Password for the LDAP Server user **Possible values:** Encrypted string **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.group.path`	Enter the complete path to the node containing the groups in the LDAP tree. → Remember We strongly recommend that you enter different paths for LDAP users and groups. That means, the value of `ldap.group.path` should be different than the value of `ldap.user.path`. **Possible values:** For example: `ldap.group.path`=*OU=Groups,OU=IAS,DC=global,DC=corp,DC=mycompany* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.user.path`	Enter the complete path to the users in the LDAP Server or Microsoft AD. → Remember We strongly recommend that you enter different paths for LDAP users and groups. That means, the value of `ldap.users.path` should be different than the value of `ldap.group.path`. **Possible values:** For example: `ldap.user.path`=*OU=Users,OU=IAS,DC=global,DC=corp,DC=mycompany* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.user.attributes`	Shows which user attributes to be read from the LDAP server (and respectively, from the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • LDAP server version 1 - Even though you specify which user attributes you want to read from the LDAP server , all user attributes are read. • LDAP server version 2 - Only the specified attributes will be read from the LDAP server. If nothing is set, all attributes are read. **System Role:** Source, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.group.attributes`	Shows which group attributes to be read from the LDAP server (and respectively, from the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • LDAP server version 1 - Even though you specify which group attributes you want to read from the LDAP server, all user and group attributes are read. • LDAP server version 2 - Only the specified attributes will be read from the LDAP server. If nothing is set, all attributes are read. **System Role:** Source, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.user.object.class`	Criteria for user. In the intermediate JSON data, the following LDAP filter is used: `(objectClass=user)` For target LDAP systems: this property defines the set of supported and required attributes for an LDAP user entity. Default value: *inetOrgPerson* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.group.object.class`	Criteria for group. In the intermediate JSON data the following LDAP filter is used: `(objectClass=group)` For target LDAP systems: this property defines the set of supported and required attributes for an LDAP group entity. Default value: *groupOfNames* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.group.uniquename.attribute`	By default, the *memberOf* array in the source JSON data contains the CN part of the complete distinguished name of the groups to which the entity belongs. An administrator can use this property to change the default behavior and specify an attribute name to be used instead of CN. **Note** • Any group that doesn't have the attribute specified, will not be part of the resulting *memberOf* JSON array. • Any group that doesn't match the `ldap.group.path` property, will not be part of the resulting *memberOf* JSON array. **Possible values:** • *cn* (default for LDAP) • *displayName* – this will produce a *memberOf* array which contains the *displayName* attribute value of the groups to which the entity belongs. **Note** Whatever value you choose for this property, it should correspond to the one in the JSON transformation of your LDAP system (the *group* mapping). **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.attribute.group.id`	This property denotes the ID of a group. • When a user is a member of a group, this group is returned in the *memberOf* array for this user. This property evaluates the attribute used as ID of this group. • When a group is a member of another group, this property evaluates the attribute used as ID of the "parent group". In this case, the `ldap.attribute.group.id` property has a higher priority than `ldap.group.uniquename.attribute`. **Possible values:** • *cn* (default) • *distinguishedName* – this will produce a *memberOf* array which contains the `distinguishedName` attribute value of the groups to which the entity belongs. **Note** Whatever value you choose for this property, it should correspond to the one in the JSON transformation of your LDAP system (the *group* mapping). **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.attribute.dn`	This property denotes the distinguished name of a user or a group. The distinguished name is auttomatically assigned and cannot be configured. The behavior described below is valid only when Microsoft Active Directory is used as target system: When the Identity Provisioning attempts to provision a user or a group to Microsoft Active Directory for the first time, it may detect that such a user or group already exists on the target system. Thus, the service needs to retrieve the entityId of the existing user or group by using this property for conflict resolution. If the service finds such a user on the target system via this filter, the creation will fail. In this case, the conflicting user will overwrite the existing one. If the service finds such a group on the target system via this filter, the creation will fail. In this case, the existing group only needs to be updated. If the service does not find a user or a group via this filter, the creation will fail. Default and only possible value: *distinguishedName* **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.member.uniquename.attribute`	Determines the value of the `member` attribute of groups in the intermediate JSON data. This property can return either the common name (CN) of the user or the entire distinguished name (DN). **Possible values:** • *cn* (default for Microsoft AD) • *uid* (default for LDAP Server) • *distinguishedName* **Note** Whatever value you choose for this property, it should correspond to the one in the JSON transformation of your system (the *user* mapping). **System Role:** Source	• LDAP Server • Microsoft Active Directory
`ldap.attribute.user.id`	This property denotes the ID of a user. When a user is a member of a group, this property evaluates the attribute used as ID of this member. In this case, the `ldap.attribute.user.id` or `ldap.attribute.group.id` property has a higher priority than `ldap.member.uniquename.attribute`. Possible values for LDAP Server: • *cn* (default for Microsoft AD) • *uid* (default for LDAP Server) • *distinguishedName* **Note** Whatever value you choose for this property, it should correspond to the one in the JSON transformation of your system (the *user* mapping). **System Role:** Source, Target, Proxy	• LDAP Server • Microsoft Active Directory
`ldap.attribute.group.member`	Default value: *member* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.user.mail`	Default value: *mail* **System Role:** Source, Target, Proxy	LDAP Server

Name	Description	System Type
`ldap.attribute.user.mobile`	Default value: *mobile* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.user.givenName`	Default value: *givenName* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.user.surname`	Default value: *sn* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.user.groups`	Default value: *memberOf* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.user.telephoneNumber`	Default value: *telephoneNumber* **System Role:** Source, Target, Proxy	LDAP Server
`ldap.attribute.group.object.class.required`	The LDAP object classes have attributes required for creation of entities. • For Open LDAP Server, the required attribute is the common name (CN) of the group. • For other implementations, it could be another attribute. Default value: *cn* **System Role:** Target, Proxy	LDAP Server
`ldap.attribute.user.object.class.required`	The LDAP object classes have attributes required for creation of entities. • For Open LDAP Server, the required attribute is the common name (CN) of the user. • For other implementations, it could be another attribute. Default value: *cn* **System Role:** Target, Proxy	LDAP Server
`ldap.respond.with.resource.after.create`	When set to *true*, the SCIM `create` operation will read the created entity from the LDAP server. Value *true* is required because the SCIM `create` operation must return the created entity. Default value: *true* **System Role:** Proxy	LDAP Server

Name	Description	System Type
`ldap.respond.with.resource.after.update`	When set to *true*, the SCIM `update` operation will read the modified entity from the LDAP server. When set to *false* or the property is missing, the `update` operation will respond with error *204* (no content). Default value: *true* **System Role:** Proxy	LDAP Server
`ldap.user.filter`	You can optimize the search to return only particular users. To enter correct user filters, stick to the standard LDAP specification. See: LDAP Representation of Filters – Examples . **Possible values:** For example: Value *(cn=123*)* will return only users whose UID starts with "123" (such as *1234567689* or *1230011*). By default, this filter is empty. That is, if the property is not specified, the filter will search for every user. **System Role:** Source	• LDAP Server • Microsoft Active Directory
`ldap.group.filter`	You can optimize the search to return only particular groups. To enter correct group filters, stick to the standard LDAP specification. See: LDAP Representation of Filters – Examples . **Possible values:** For example: Value *(cn=mar*)* will return only groups whose CN starts with "mar" (such as *marked*, *March*, or *Marketing*). By default, this filter is empty. That is, if the property is not specified, the filter will search for every group. **System Role:** Source, Proxy	• LDAP Server • Microsoft Active Directory

Name	Description	System Type
`ldap.page.size`	Use this property to configure the paging (pagination). That means, the number of entities to be read from the LDAP server at once. Default value: *100* **Note** It is not recommended to exceed *1000*. **System Role:** Source	• LDAP Server • Microsoft Active Directory
`ldap.api.version`	Defines the version of LDAP Server API. **Possible values:** • **1** - Indicates that LDAP Server API version 1 is used. • **2** - Indicates that LDAP Server API version 2 is used. If the property is not defined - LDAP Server API version 1 is used. **System Role:** Source, Target, Proxy	LDAP Server
`concur.page.size`	Use this property to configure the paging. That means, the number of entities to be read from Concur at once. Default value: *100* **Note** The maximum allowed number is 100. **System Role:** Source	SAP Concur (Using User v1 API)

Name	Description	System Type
`concur.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. **Note** Use this property when your SAP Concur connector is configured for version 3. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *1000* Minimum value: *1* Maximum value: *1000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Concur target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP Concur target system to update the group.	SAP Concur (using SCIM v4 API)

Name	Description	System Type
	Note If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in SAP Concur, the maximum number of members which can be removed per one PATCH request is 1000. **System Role:** Target	

Name	Description	System Type
`concur.group.members.page.size`	Defines the number of group members that SAP Concur returns per request when reading a group. **Note** Use this property when your SAP Concur connector is configured for version 3. When Identity Provisioning reads a group, it compares the number of group members with the value configured for `concur.group.members.page.size`. • If the number of group members is equal to or greater than the configured page size and the `concur.group.members.paging.enabled` property is set to *true*, Identity Provisioning will read all group members in separate requests. For example, if a group has 6 members and the page size is set to *2*, Identity Provisioning will send 3 requests to read the group members. • If the number of group members is less than the page size or `concur.group.members.paging.enabled` is set to false, Identity Provisioning will read all group members in a single request. For example, if a group has 2 members and the page size is set to *6*, Identity Provisioning will read all group members in a single request. Setting the property `concur.group.members.paging.enabled` allows you to read groups with a large number of group members. For more information, see `concur.group.members.paging.enabled`. **Default value:** 1000 **System Role:** Source, Proxy	SAP Concur (using SCIM v4 API)

Name	Description	System Type
`concur.group.members.paging.enabled`	This property enables paging of group members. **Note** Use this property when your SAP Concur connector is configured for version 3. The maximum number of group members returned per request is 1000. To read more than 1000 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **System Role:** Source, Proxy	SAP Concur (using SCIM v4 API)

Name	Description	System Type
`ibp.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. **Note** Use this property when your SAP Integrated Business Planning connector is configured for version 2. - If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. - If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** - *true* - *false* Default value: *false* **System Role:** Target, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`s4hana.cloud.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. **Note** Use this property when your SAP S/4HANA Cloud Public Edition connector is configured for version 3. - If set to *true*, **PATCH** operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. - If set to *false*, **PUT** operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** - *true* - *false* Default value: *false* **System Role:** Target, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`concur.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. **Note** Use this property when your SAP Concur connector is configured for version 3. - If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. - If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** - *true* - *false* Default value: *false* **System Role:** Target, Proxy	SAP Concur (using SCIM v4 API)

Name	Description	System Type
`concur.group.prefix`	This property distinguishes SAP Concur groups by specific prefix. It is an optional property which does not appear by default at system creation. **Note** Use this property when your SAP Concur connector is configured for version 3. Example value: **`Concur_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Concur source system and will be provisioned to the target system with the following name pattern: **`Concur_<GroupDisplayName>`**. This way SAP Concur groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Concur groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`Concur_`** prefix in their display name will be provisioned to SAP Concur. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Concur. **System Role:** Source and Target	SAP Concur (using SCIM v4 API)

Name	Description	System Type
`concur.group.unique.attribute`	This property defines by which unique attribute(s) the existing group will be searched and resolved. **Note** Use this property when your SAP Concur connector is configured for version 3. The default value is *displayName*. If the service finds an existing group by this unique attribute, the group that you try to provision will overwrite the existing one. If such a group is not found, the group that you try to provision will not be created in the target system. **System Role:** Target	SAP Concur (using SCIM v4 API)
`concur.group.filter`	When specified, only those groups matching the filter expression will be read. **Note** Use this property when your SAP Concur connector is configured for version 3. For example: *displayName* eq "ProjectTeam1" **System Role:** Source and Proxy	SAP Concur (using SCIM v4 API)
`msgraph-filter(Deprecated)`	Use this property to filter users and groups by specific criteria, according to the API syntax of Microsoft Entra ID. **Note** This property is deprecated. Use `aad.user.filter` and `aad.group.filter` instead. Default value: *null* To set a particular value, see Microsoft Graph: filter parameter . **System Role:** Source	Microsoft Entra ID

Name	Description	System Type
`gsuite.page.size`	Use this property to configure the paging. That means, the number of entities to be read from Google G Suite at once. Default value: *100* **Note** The maximum allowed number is 500. **System Role:** Source	Google G Suite
`gsuite.get.deleted`	This property determines whether recently deleted entities should be read. **Note** You can apply this property only for **users**. For groups it will be ignored. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source	Google G Suite
`gsuite.domain`	This property determines whether entities from a particular domain should be read. **Possible values:** For example: *myaccount.ondemand.com* **System Role:** Source	Google G Suite
`gsuite.customer.id`	This property determines whether entities for a particular customer ID to be read. This property takes precedence over `gsuite.domain`. **Possible values:** Customer ID number For more information, see Google G Suite API: User Accounts . **System Role:** Source	Google G Suite

Name	Description	System Type
`com.sun.jndi.ldap.read.timeout`	Use this property if you want to specify the read timeout (in milliseconds) for an LDAP connection. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values:** For example: *5000* This value causes the LDAP service provider to abort the read attempt if the server does not respond within 5 seconds. **System Role:** Source	• LDAP Server • Microsoft Active Directory
`com.sun.jndi.ldap.connect.timeout`	Use this property if you want to set the timeout (in milliseconds) for connecting to the LDAP server. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values:** For example: *500* This value causes the LDAP service provider to abort the connection attempt if a connection cannot be established in half a second. **System Role:** Source	• LDAP Server • Microsoft Active Directory
`aad.oauth2.resource.name`	Specifies the OAuth2 resource name for Microsoft Graph API. **Default value:** `https://graph.microsoft.com` You can change the Microsoft Graph endpoint to match your organization's cloud environment. For more information, see Microsoft Graph national cloud deployments . **System role:** Source, Target, Proxy	Microsoft Entra ID

Name	Description	System Type
`ad.group.flatten`	There are target systems that do not support nested groups (group structures). Therefore, if your Microsoft AD system contains such groups, they will not be resolved properly during the provisioning job. Such target systems are: • *SAP Jam Collaboration* • *Identity Authentication* To enable reading of group structures, you can use the `ad.group.flatten` property and set it to *true*. It will read the group structure recursively and will "flatten" it so that all users from all groups and subgroups will be resolved and written in the target system as members of the main parent group. For best results, we recommend you also set the system property `ldap.group.filter` whose value is one or multiple Microsoft AD parent groups. **Possible values:** • *true* • *false* Default value: *false* Examples for filtering: • If your Microsoft AD system contains a parent group "*Canteen*", which contains nested subgroups, you have to set the filter like this: `ldap.group.filter` = *(cn=Canteen)* The Identity Provisioning will resolve all the direct users and groups of "*Canteen*", along with all the users of its subgroups (and their subgroups). In the target system, all users will be written in one parent group named also "*Canteen*". • If you have multiple parent groups (for example, *Canteen*, *Finances*, and *Support_Team*) that contain nested subgroups, you have to set the filter like this: `ldap.group.filter` = *(|(cn=Canteen)(cn=Finance)(cn=Support_Team))* **System Role:** Source	Microsoft Active Directory

Name	Description	System Type
`aad.domain.name`	Enter one of the verified domain names from the corresponding Microsoft Entra ID tenant. **System Role:** Source, Target, Proxy	Microsoft Entra ID
`aad.group.member.attributes`	This property defines the attributes of a group member to be read by the Identity Provisioning. By default, it always reads the *type* and the *id* of a member. If you prefer the Identity Provisioning to read additional attributes, you can add them as a single or a comma-separated value. For example: **Example** • If you want to read the e-mails too, enter: `aad.group.member.attributes` =*mail* This will read a member's type, ID and e-mail. • If you want to read multiple additional attributes, enter: `aad.group.member.attributes` =*mail,mobilePhone,displayName* This will read a member's type, ID, e-mail, phone and display name. See: Microsoft Entra ID [page 914] **Possible values:** • *type* (default) • *id* (default) • Any valid Microsoft Entra ID attribute of a group member • A comma-separated list of valid Microsoft Entra ID attributes of a group member **→ Remember** The Identity Provisioning service always retrieves the *id* and *type* attributes of a group member, regardless of the additional attributes you specify. **System Role:** Source, Proxy	Microsoft Entra ID

Name	Description	System Type
`aad.user.attributes.membership.active`	Use this property if you want to get information about all the groups to which the users are assigned (if any). • If the property is missing, or is set to *false* – group membership details for the users will not be extracted. • If the property is set to *true* – group membership details for the users will be extracted. If you set the property to *true*, you will get information about the group ID and its entity type (group) – default result. However, if you also set a value for property `aad.group.attributes`, you will get additional information relevant to this value. For example: If you set `aad.user.attributes.membership.active` = *true* and `aad.group.attributes` = *displayName*, you will receive the following exemplary data for a group as part of the user object: `"groups": [ { "displayName": "Microsoft Entra ID Group 1", "id": "aaa111999-0000-444-123-777fff000", "type": "group" } ]` **Possible values:** • *true* • *false* (default) **System Role:** Source, Proxy	Microsoft Entra ID

Name	Description	System Type
`aad.user.filter`	Via this property, you can filter users by specific criteria, according to the syntax of Microsoft Graph REST API . You can also filter out users with advanced query parameters, as described in Advanced query capabilities on Microsoft Entra ID objects **Note** This property replaces the deprecated `msgraph-filter` property. **Possible values:** Text/numeric string For example: • Value = *Department eq 'Finance'* • Value = *displayName eq 'John Smith' and city eq 'Sofia'* • Value = *userPrincipalName ne 'Julie Armstrong'* **System Role:** Source, Proxy	Microsoft Entra ID
`aad.group.filter`	Via this property, you can filter groups by specific criteria, according to the syntax of Microsoft Graph REST API . You can also filter out groups with advanced query parameters, as described in Advanced query capabilities on Microsoft Entra ID objects **Possible values:** Text/numeric string For example: • Value = *displayName eq 'Employees 2020'* • Value = *displayName eq 'Service Administrators' and mail eq 'serviceadmins@abcd.onmicrosoft.com'* • Value = *startsWith(displayName, 'ABC_')* • Value = *displayName ne 'Service Administrators'* **System Role:** Source, Proxy	Microsoft Entra ID

Name	Description	System Type
`aad.user.attributes`	Defines which user attributes are read from Microsoft Entra ID system. The property is set during system creation with the following default value: *id,mail,userPrincipalName,displayName,mailNickname,givenName,surname,mobilePhone,businessPhones* This means that by default, Identity Provisioning will read from Microsoft Entra ID the user attributes defined in the property value. Those attributes are also used in the default read transformation. To check the complete set of user attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: User Properties If you want the Identity Provisioning to read additional user attributes, add them to the default list of attributes separated by comma and adapt the transformations. For example, to read the *employeeId* of the Microsoft Entra ID users in addition to the default list of attributes, and provision them to Identity Authentication, proceed as follows: 1. Add the attribute in the property value: id,mail,userPrincipalName,displayName,mailNickname,givenName,surname,mobilePhone,businessPhones,*employeeId* 2. Extend the Microsoft Entra ID read transformation by adding the following mapping for the user resource: Sample Code `{ "sourcePath": "$.employeeId", "targetPath": "$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['employeeNumber']", "optional": true },`	Microsoft Entra ID

Name	Description	System Type
	3. Make sure the following mapping is present in the Identity Authentication write transformation: **Sample Code** `{ "sourcePath": "$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['employeeNumber']", "targetPath": "$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['employeeNumber']", "optional": true },` In case you remove the default list of attributes from the value of this property and only add the additional attributes, Identity Provisioning will return the additional user attributes plus the mandatory ones: *id,mail, userPrincipalName*. **System Role:** Source, Proxy	

Name	Description	System Type

`aad.group.attributes`	Defines which group attributes are read from Microsoft Entra ID system.
	
	The property is set during system creation with the following default value: *id,displayName,mailNickname*
	
	This means that by default, Identity Provisioning will read from Microsoft Entra ID the group attributes defined in the property value and will also return the *members* attribute. Those attributes are used in the default read transformation.
	
	To check the complete set of group attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: Group Properties
	
	If you want the Identity Provisioning to read additional group attributes, add them to the default list of attributes separated by comma and adapt the transformations.
	
	For example, to read the *description* of the Microsoft Entra ID groups in addition to the default list of attributes, and provision them to Identity Authentication, proceed as follows:
	
	1. Add the attribute in the property value: id,displayName,mailNickname,*description*
	2. Extend the Microsoft Entra ID read transformation by adding the following mapping for the group resource:
	
	Code Syntax
	`{ "sourcePath": "$.description", "optional": true, "targetPath": "$.description" },`
	
	3. Extend the Identity Authentication write transformation by adding the following mapping for the group resource:
	
	Code Syntax
	`{ "sourcePath": "$.description",`
		Microsoft Entra ID

Name	Description	System Type
	 In case you remove the default list of attributes from the value of this property and only add the additional attributes, Identity Provisioning will read from Microsoft Entra ID the additional group attributes, the group *id*, *displayName*, *mailNickname* and will also return the *members* attribute. **System Role:** Source, Proxy	
`aad.entities.top`	This property defines the number of entities to be read per page. Default value: *100* **System Role:** Source, Proxy	Microsoft Entra ID
`csrf.token.path`	Path which is appended to the URL to retrieve the CSRF token. The property can be configured for the following provisioning systems: • SCIM System • SAP Analytics Cloud **System Role:** Target, Proxy	• SAP Analytics Cloud • SCIM System

Name	Description	System Type
`sac.csrf.token.path`	Path which is appended to the URL to retrieve the CSRF token. The property is automatically added during system creation, when the SAP Analytics Cloud system consumes SCIM API version 2. Based on the version of the SCIM API consumed, the default value for the property is: • SAP Analytics Cloud SCIM API version 1: `/api/v1/scim/Users?count=1` **Note** The property is present only for systems created before December 3, 2024. Systems created after this date use the default value for the connector version without adding the property. • SAP Analytics Cloud SCIM API version 2: `/api/v1/scim2/Users?count=1` **Note** If you delete the property, Identity Provisioning will use the default value for the property for SAP Analytics Cloud using SCIM API **version 1**. **System Role:** Target, Proxy	SAP Analytics Cloud
`scim.csrf.token.path`	Specifies the path which is appended to the URL to retrieve the CSRF token when `scim.api.csrf.protection` is enabled. The property is not automatically added during system creation. **Note** A CSRF token will be fetched upon request only when `scim.api.csrf.protection` is set to *enabled*. **System Role:** Target, Proxy	SCIM System

Name	Description	System Type
`s4hana.cloud.hr.switch.active`	Defines whether the human resources (HR) integration is active or not. The property is set to `true` by default. This means that the synchronization of business partners is managed by the HR system and SAP S/4HANA Cloud Public Edition. Identity Provisioning can only be used for managing business users (login users and their login information, such as date/time preferences) and role assignments. When set to `false`, synchronization is handled by the identity management system instead. **Possible values:** • *true* (default) • *false* **System Role:** Target, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.cloud.roles.filter`	Enter OData filtering for reading roles in the SAP S/4HANA Cloud Public Edition system. To learn what criteria you can use, see: OData URI Conventions → 4.5 Filter System Query Option **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.cloud.api.version`	This property defines the API version that your SAP S/4HANA Cloud Public Edition system uses. By default, Identity Provisioning uses version *1*. Version *1* means your SAP S/4HANA Cloud Public Edition system consumes SAP S/4HANA Cloud Public Edition API: Business User. Version *3* means your SAP S/4HANA Cloud Public Edition system consumes System for Cross-domain Identity Management (SCIM) API. **System Role:** Source, Target, Proxy	SAP S/4HANA Cloud Public Edition

Name	Description	System Type
`s4hana.cloud.group.filter`	When specified, only those SAP S/4HANA Cloud Public Edition groups matching the filter expression will be read. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values**: • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For example: • *displayName co "ProjectTeam1" or "Students2023"* • *externalId eq "12345678" or externalId sw "123"* • *urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type eq "authorization" and externalId eq "12345678"* **Note** These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`s4hana.cloud.group.prefix`	This property distinguishes SAP S/4HANA Cloud Public Edition groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`S4HANACLOUD_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP S/4HANA Cloud Public Edition source system and will be provisioned to the target system with the following name pattern: **`S4HANACLOUD_<GroupDisplayName>`**. This way SAP S/4HANA Cloud Public Edition groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP S/4HANA Cloud Public Edition groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`S4HANACLOUD_`** prefix in their display name will be provisioned to SAP S/4HANA Cloud Public Edition. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP S/4HANA Cloud Public Edition. **System Role:** Source and Target	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`s4hana.cloud.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP S/4HANA Cloud Public Edition target system, the creation will fail. In this case, the existing group only needs to be updated. In SAP S/4HANA Cloud Public Edition the uniqueness of a group is defined by the combination of the following two attributes, which are automatically filled in when the target system is created: *externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']*. To resolve the conflict, an existing group must match both of these attributes. If the group matches only one of the attributes, the conflict is not resolved, and group creation will fail. **Note** Although you can define your own unique combination of attributes (for example, *externalId,displayName*), we recommend that you do not modify the automatically filled value of the `s4hana.cloud.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute *displayName*. **System Role:** Target	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`s4hana.cloud.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *20000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP S/4HANA Cloud Public Edition target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP S/4HANA Cloud Public Edition target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
	must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in SAP S/4HANA Cloud Public Edition, the maximum number of members which can be removed per one **PATCH** request is 50. **System Role:** Target	
`s4hana.cloud.user.filter`	When specified, only those SAP S/4HANA Cloud Public Edition users matching the filter expression will be read. You can filter users by **list of attributes** according to the API syntax of SAP S/4HANA Cloud Public Edition. You can set a single attribute or multiple ones as filter criteria. If you enter multiple attributes (using OR operator), the filter will search for any of them. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values:** • `userName` • `externalId` • `emails[0].value` For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName sw "J" or externalId eq "P000252"* • *userName eq "johnbrown" and emails[0].value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails[0].value ne "johnbrown@email.com" or externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)

Name	Description	System Type
`s4hana.cloud.hr.switch.dependent.role.codes`	A default property. Add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your read and write transformations. **Possible values:** For example: *BUP003, BBP005* That means, your HR integration will support *employees* and *contingent worker*. **System Role:** Target, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.cloud.skip.read.archived`	In the event of archived (disabled) entities in a source SAP S/4HANA Cloud Public Edition system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source and proxy systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.onprem.hr.switch.dependent.role.codes`	Add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your read and write transformations. This property is applicable only if `s4hana.onprem.hr.switch.active` = *true* **Possible values:** For example: *BUP003, BBP005, BUP012, WFM001* That means, your HR integration will support *employees*, *contingent workers*, *collaboration users*, and *resources*. **System Role:** Target, Proxy	SAP S/4HANA On-Premise

Name	Description	System Type
`s4hana.onprem.hr.switch.active`	Defines whether the system should include HR integration or not. This property is related to `s4hana.onprem.hr.switch.dependent.role.codes`. **Possible values:** • *true* – HR integration is enabled for your system • *false* – HR integration is disabled for your system Default value: *false* **System Role:** Target, Proxy	SAP S/4HANA On-Premise
`s4hana.onprem.skip.read.archived`	In the event of archived (disabled) entities in a source SAP S/4HANA On-Premise system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source and proxy systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Proxy	SAP S/4HANA On-Premise
`s4hana.onprem.sap-client`	Use this property if you want to specify a particular AS ABAP client to use as the `sap-client` URL parameter. AS ABAP client. To learn more, see: Specifying the Client For more information about `sap-client`, see: SAP URL Parameters **Possible values:** A three-digit integer number For example: *102* **System Role:** Source, Target, Proxy	SAP S/4HANA On-Premise

Name	Description	System Type
`s4hana.onprem.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source, Target, Proxy	SAP S/4HANA On-Premise
`s4hana.onprem.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP S/4HANA On-Premise

Name	Description	System Type
`fg.group.prefix`	This property distinguishes SAP Fieldglass groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **FG_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Fieldglass source system and will be provisioned to the target system with the following name pattern: **FG_<GroupDisplayName>**. This way SAP Fieldglass groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Fieldglass groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **FG_** prefix in their display name will be provisioned to SAP Fieldglass. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Fieldglass. **System Role:** Source and Target	SAP Fieldglass
`fg.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning users and groups. This means, the Identity Provisioning service can write, update, and delete multiple users in a single request. For more information, see: SAP Fieldglass Identity Management API **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Fieldglass

Name	Description	System Type
`fg.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. **Possible values:** Default value: *20* Minimum value: *10* Maximum value: *100* If you provide a value outside of the minimum and maximum range, the service will replace it with the default value (20). **System Role:** Target	SAP Fieldglass
`a4c.skip.read.archived`	In the event of archived (disabled) entities in a source SAP BTP ABAP environment system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source and proxy systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Target, Proxy	SAP BTP ABAP environment
`a4c.roles.filter`	Enter OData filtering for reading roles in the SAP BTP ABAP environment system. To learn what criteria you can use, see: OData URI Conventions → 4.5 Filter System Query Option **System Role:** Source, Proxy	SAP BTP ABAP environment

Name	Description	System Type
`a4c.roles.prefix`	This property distinguishes SAP BTP ABAP environment roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`A4C_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP BTP ABAP environment source system and will be provisioned to the target system with the following name pattern: **`A4C_<role_name>`** . This way SAP BTP ABAP environment roles in the target system will be easily distinguished from roles provisioned from other applications. If the property is not set, the SAP BTP ABAP environment roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **`A4C_`** prefix in their role name will be provisioned to SAP BTP ABAP environment. Roles without this prefix in their names won't be provisioned. If the property is not set, all roles will be provisioned to SAP BTP ABAP environment. **System Role:** Source and Target	SAP BTP ABAP environment

Name	Description	System Type
`a4c.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP BTP ABAP environment target or proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Possible values:** • *true* – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • *false* – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* **System Role:** Target, Proxy	SAP BTP ABAP environment

Name	Description	System Type
`ibp.roles.prefix`	This property distinguishes SAP Integrated Business Planning roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IBP_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP Integrated Business Planning source system and will be provisioned to the target system with the following name pattern: **`IBP_<role_name>`** . This way SAP Integrated Business Planning roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Integrated Business Planning roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **`IBP_`** prefix in their role name will be provisioned to SAP Integrated Business Planning. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be provisioned to SAP Integrated Business Planning. **System Role:** Source and Target	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)

Name	Description	System Type
`ibp.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP IBP target or proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Possible values:** • *true* – the current user roles will be deleted in the target or proxy system, and the user will be updated only with the roles provisioned by the service. • *false* – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target or proxy system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* **System Role:** Target, Proxy	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)
`marketing.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Marketing Cloud target or proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Possible values:** • *true* – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • *false* – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* **System Role:** Target, Proxy	SAP Marketing Cloud

Name	Description	System Type
`s4hana.cloud.roles.page.size`	This property indicates how many business roles (considered as *groups*) per page to be read from your SAP S/4HANA Cloud Public Edition source system. **Possible values:** Integer number For example, if you set the property's value = *30*, the Identity Provisioning will read 30 roles (groups) at once, then – another 30, and so on. **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.cloud.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`s4hana.cloud.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)

Name	Description	System Type
`marketing.cloud.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Marketing Cloud
`marketing.cloud.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP Marketing Cloud
`a4c.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP BTP ABAP environment

Name	Description	System Type
`a4c.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP BTP ABAP environment
`a4c.roles.page.size`	This property indicates how many business roles (considered as *groups*) per page to be read from your SAP BTP ABAP environment source system. **Possible values:** Integer number For example, if you set the property's value = *30*, the Identity Provisioning will read 30 roles (groups) at once, then – another 30, and so on. **System Role:** Source, Proxy	SAP BTP ABAP environment
`ibp.roles.page.size`	This property indicates how many business roles (considered as *groups*) per page to be read from your SAP IBP source system. **Possible values:** Integer number For example, if you set the property's value = *30*, the Identity Provisioning will read 30 roles (groups) at once, then – another 30, and so on. **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)
`ibp.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)

Name	Description	System Type
`ibp.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)
`ibp.api.version`	This property defines the API version which is consumed by the SAP Integrated Business Planning system. **Possible values:** • *1* - SAP Integrated Business Planning API: Business User is used. • *2* - SCIM Interface for IAM is used. By default, Identity Provisioning uses version *1*. **System Role:** Source, Target, Proxy	SAP Integrated Business Planning

Name	Description	System Type
`ibp.group.filter`	When specified, only those SAP Integrated Business Planning groups matching the filter expression will be read. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values**: • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For example: • *displayName co "ProjectTeam1" or "Students2023"* • *externalId eq "12345678" or externalId sw "123"* • *urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type eq "authorization" and externalId eq "12345678"* **Note** These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`ibp.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP Integrated Business Planning target system, the creation will fail. In this case, the existing group only needs to be updated. In SAP Integrated Business Planning the uniqueness of a group is defined by the combination of the following two attributes, which are automatically filled in when the target system is created: *externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']*. To resolve the conflict, an existing group must match both of these attributes. If the group matches only one of the attributes, the conflict is not resolved, and group creation will fail. **Note** Although you can define your own unique combination of attributes (for example, *externalId,displayName*), we recommend that you do not modify the automatically filled value of the `ibp.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute *displayName*. **System Role:** Target	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`ibp.group.prefix`	This property distinguishes SAP Integrated Business Planning groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IBP_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Integrated Business Planning source system and will be provisioned to the target system with the following name pattern: **`IBP_<GroupDisplayName>`**. This way SAP Integrated Business Planning groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Integrated Business Planning groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`IBP_`** prefix in their display name will be provisioned to SAP Integrated Business Planning. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Integrated Business Planning. **System Role:** Source and Target	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`ibp.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *20000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Integrated Business Planning target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP Integrated Business Planning target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
	must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in SAP Integrated Business Planning, the maximum number of members which can be removed per one **PATCH** request is 50. **System Role:** Target	
`ibp.user.filter`	When specified, only those SAP Integrated Business Planning users matching the filter expression will be read. You can filter users by **list of attributes** according to the API syntax of SAP Integrated Business Planning. You can set a single attribute or multiple ones as filter criteria. If you enter multiple attributes (using OR operator), the filter will search for any of them. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values:** • `userName` • `externalId` • `emails[0].value` For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName sw "J" or externalId eq "P000252"* • *userName eq "johnbrown" and emails[0].value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails[0].value ne "johnbrown@email.com" or externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)

Name	Description	System Type
`marketing.cloud.roles.page.size`	This property indicates how many business roles (considered as *groups*) per page to be read from your SAP Marketing Cloud source system. **Possible values:** Integer number For example, if you set the property's value = *30*, the Identity Provisioning will read 30 roles (groups) at once, then – another 30, and so on. **System Role:** Source, Proxy	SAP Marketing Cloud
`marketing.cloud.roles.prefix`	This property distinguishes SAP Marketing Cloud roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SMKC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP Marketing Cloud source system and will be provisioned to the target system with the following name pattern: **`SMKC_<role_name>`** . This way SAP Marketing Cloud roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Marketing Cloud roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **`SMKC_`** prefix in their role name will be provisioned to SAP Marketing Cloud. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be provisioned to SAP Marketing Cloud. **System Role:** Source and Target	SAP Marketing Cloud

Name	Description	System Type
`s4hana.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP S/4HANA Cloud Public Edition target or proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Possible values:** • *true* – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • *false* – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* **System Role:** Target, Proxy	SAP S/4HANA Cloud Public Edition (using version 1 - SAP S/4HANA Cloud Public Edition API: Business User)
`ibp.skip.read.archived`	In the event of archived (disabled) entities in a source SAP IBP system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Target, Proxy	SAP Integrated Business Planning
`ibp.roles.filter`	Enter OData filtering for reading roles in the SAP IBP system. To learn what criteria you can use, see: OData URI Conventions → 4.5 Filter System Query Option **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 1 - SAP Integrated Business Planning API: Business User)

Name	Description	System Type
`marketing.cloud.skip.read.archived`	In the event of archived (disabled) entities in a source SAP Marketing Cloud system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source and proxy systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Target, Proxy	SAP Marketing Cloud
`marketing.cloud.roles.filter`	Enter OData filtering for reading roles in the SAP Marketing Cloud system. To learn what criteria you can use, see: OData URI Conventions → 4.5 Filter System Query Option **System Role:** Source, Proxy	SAP Marketing Cloud
`scim.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. If enabled, this property requires the configuration of the `scim.csrf.token.path` property to specify the path where the CSRF token can be retrieved. **Possible values:** • *enabled* • *disabled* > **Note** > If the property is missing, its default value is **disabled**. **System Role:** Target, Proxy	SCIM System

Name	Description	System Type
`sac.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. The property is automatically added in the system, with default value: *enabled*. **Possible values:** • *enabled* • *disabled* Default value: *enabled* **Note** If the property is missing, its default value is *disabled*. **System Role:** Target, Proxy	SAP Analytics Cloud
`sac.support.bulk.operation`	This property enables bulk operations for users. When bulk operations are enabled (set to *true*), Identity Provisioning service creates, updates, and deletes multiple users in one request. When bulk operations are not enabled (set to *false*), Identity Provisioning service creates, updates, and deletes one user at a time. For more information, see: SCIM Protocol: Bulk Operations **Note** SCIM bulk operations are not supported for provisioning groups to SAP Analytics Cloud. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Analytics Cloud

Name	Description	System Type
`sac.bulk.operations.max.count`	If you have enabled the SCIM bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: • *100* - when using SAP Analytics Cloud SCIM API version 1. • *30* - when using SAP Analytics Cloud SCIM API version 2. **Note** The value must not exceed the number of entities defined by the SAP Analytics Cloud system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Payload Too Large*). **System Role:** Target	SAP Analytics Cloud
`scim.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** For example: *name.familyName eq "SmithJ" and addresses.country eq "US"* **System Role:** Source	All SCIM-based systems

Name	Description	System Type
`scim.group.filter`	When specified, only those groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1" or "Students2018"* **System Role:** Source	• Identity Authentication • Local Identity Directory • SAP Advanced Financial Closing • SAP Analytics Cloud • SAP Ariba Applications • SAP Ariba Central Invoice Management • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP CPQ • SAP Data Custodian • SAP Enable Now • SAP Enterprise Portal • SAP Fieldglass • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors version 2 • SAP SuccessFactors Employee Central Payroll • SAP SuccessFactors Incentive Management • Sales Cloud – Analytics & AI • Cloud Foundry UAA Server • Procurement Data Warehouse • SCIM System • SSH Server (Beta)

Name	Description	System Type
`scim.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	All SCIM-based systems

Name	Description	System Type
`scim.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. **Note** Relevant only for *Identity Authentication* and *SAP Analytics Cloud*: • For systems created **before** `April 7, 2020`, this property is missing during system creation, and it has the default value, *userName*. If the service does not find an existing user with such a *userName*, it will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is unsuccessful too, the creation of the conflicting user fails. • For systems created **after** `April 7, 2020`, this property appears by default during system creation, and its value is set to *userName*. If the service does not find an existing user with such a *userName*, the creation of the conflicting user fails. However, if you delete the property, the service will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is un-	All SCIM-based systems

Name	Description	System Type
	successful too, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes **Note** • *phoneNumbers[0].value* - supported unique attribute for Local Identity Directory (when Identity Provisioning is running on SAP Cloud Identity Infrastructure) Default value: *userName* **System Role:** Target	

Name	Description	System Type
`scim.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `scim.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	• Identity Authentication • Local Identity Directory • SAP Advanced Financial Closing • SAP Analytics Cloud • SAP Ariba Applications • SAP Ariba Central Invoice Management • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP CPQ • SAP Data Custodian • SAP Enable Now • SAP Enterprise Portal • SAP Fieldglass • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors version 2 • SAP SuccessFactors Employee Central Payroll • SAP SuccessFactors Incentive Management • Sales Cloud – Analytics & AI • Cloud Foundry UAA Server • Procurement Data Warehouse • SCIM System • SSH Server (Beta)

Name	Description	System Type
`scim.group.members.additional.attributes`	Defines additional attributes you can request from an **Identity Authentication** source system when reading groups. If you read groups through REST API, use the **GET** request. Add the additional attributes (coma-separated) as a value of the URL parameter `membersAdditionalAttributes`. **Possible values:** a coma-separated list of attribute names You can add the following attributes: • *emails* • *userName* • *displayName* • *urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:employeeNumber* **System Role:** Source	Identity Authentication (SCIM API version 1)
`scim.include.if.match.wildcard.header`	Makes the connector send the `If-Match` HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	All SCIM-based systems

Name	Description	System Type
`scim.support.patch.operation`	If your target or proxy system is among the SCIM-based ones listed under *System Type* and supports PATCH operations, set this property to *true*. This way, when the Identity Provisioning identifies a changed entity in the source system, it will execute the updates as PATCH requests instead of PUT. That means, only the changes will be written in the target system, instead of provisioning the whole entity data. Note that only attributes without `"scope"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with scope, such as: `{ "constant": "xsuaa-dummy-value", "targetPath": "$.id", "scope": "createEntity" }` **Additional Information:** There are different cases when an entity should be updated in the target system: • In the source system, some of the entity attributes have been changed, or new attributes have been added. • In the source system, a condition or a filter is set for this entity not to be read anymore. • The whole entity has been deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false*	• Identity Authentication (SCIM API version 2) • Local Identity Directory • Cloud Foundry UAA Server • SAP BTP XS Advanced UAA (Cloud Foundry) • SCIM System • SAP Ariba Applications • SAP Ariba Category Management • SAP Advanced Workflow • SAP Business Network • SAP Commerce Cloud • SAP Build Work Zone, standard edition • SAP Ariba Central Invoice Management • SAP Data Custodian • SAP Datasphere • SAP Jam Collaboration • SAP SuccessFactors Employee Central Payroll • SAP Field Service Management • SAP HANA Cloud Database Services • SAP Intelligent Agriculture • SAP SuccessFactors (SCIM API version 2) • SAP SuccessFactors Learning • SAP Advanced Financial Closing • SAP Analytics Cloud • SAP Build Work Zone, advanced edition

Name	Description	System Type
	System Role: Target, Proxy	
`jam.group.prefix`	This property distinguishes SAP Jam Collaboration groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SJC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Jam Collaboration source system and will be provisioned to the target system with the following name pattern: **`SJC_<GroupDisplayName>`**. This way SAP Jam Collaboration groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Jam Collaboration groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`SJC_`** prefix in their display name will be provisioned to SAP Jam Collaboration. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Jam Collaboration. **System Role:** Source and Target	SAP Jam Collaboration
`scp.user.userbase`	This property specifies the host to the identity provider to be used with this target system. All provisioned users can be authenticated only by this identity provider. If you use another IdP, enter its value as configured in the SAP BTP cockpit. For example: `<account_ID>.accounts.ondemand.com` Default value: *accounts.sap.com* **System Role:** Target, Proxy	SAP BTP Account Members (Neo)

Name	Description	System Type
`AuthType`	Enter the type of authentication used for access token retrieval for OAuth HTTP destinations. **Possible values:** • *Basic* • *Form* Default value: *Basic* **System Role:** Source, Target, Proxy	• SCIM System • SAP Analytics Cloud • SAP SuccessFactors Incentive Management • SAP Jam Collaboration • Identity Authentication • Local Identity Directory • Cloud Foundry UAA Server • SAP BTP XS Advanced UAA (Cloud Foundry) • Sales Cloud – Analytics & AI • SAP BTP Account Members (Neo) • SAP Fieldglass • SAP Ariba Applications
`CloudConnectorLocationId`	Relevant when the `ProxyType` property is set to *OnPremise*. Use it in case your SAP Business Technology Platform account uses more than one Cloud Connector or when the Cloud Connector uses `LocationID`. **Possible values:** String **System Role:** Source, Target, Proxy	• SSH Server (Beta) • SAP HANA Database • LDAP Server • Microsoft Active Directory • SAP S/4HANA On-Premise • All HTTP systems
`hana.jdbc.db.user`	Name of the SAP HANA Database user **System Role:** Target	SAP HANA Database
`hana.jdbc.db.password`	(Credential) **System Role:** Target	SAP HANA Database
`hana.jdbc.db.host`	SAP HANA Database host **System Role:** Target	SAP HANA Database
`hana.jdbc.db.port`	SAP HANA Database port **Default value:** *30015* **System Role:** Target	SAP HANA Database

Name	Description	System Type
`hana.jdbc.db.encrypt`	This property enables or disables TLS encryption. Possible values: • **true** (Default value) • **false** **Note** For existing systems, the property value defaults to **false**. **System Role:** Target	SAP HANA Database
`hana.jdbc.db.validateCertificate`	When set to true, this property specifies that the server certificate is validated. When set to false, the certificate is not validated. Possible values: • **true** (Default value) • **false** **System Role:** Target	SAP HANA Database
`sales.cloud.analytics_ai.user.filter`	Use this property to filter users by specific criteria, according to the API syntax of SCAAI. **Possible values:** Text/numeric string For example: *externalId eq "John123"* **System Role:** Source, Proxy	Sales Cloud – Analytics & AI
`sales.cloud.analytics_ai.group.filter`	Use this property to filter groups by specific criteria, according to the API syntax of SCAAI. **Possible values:** Text/numeric string For example: *displayName eq "first_group"* **System Role:** Source, Proxy	Sales Cloud – Analytics & AI
`ssh.read.users.command`	Path to the bash command you need to execute to read users. **System Role:** Source	SSH Server (Beta)
`ssh.create.user.command`	Path to the bash command you need to execute to create a user. **System Role:** Source, Target	SSH Server (Beta)

Name	Description	System Type
`ssh.update.user.command`	Path to the bash command you need to execute to update a user. **System Role:** Source, Target	SSH Server (Beta)
`ssh.delete.user.command`	Path to the bash command you need to execute to delete a user. **System Role:** Source, Target	SSH Server (Beta)
`ssh.read.groups.command`	Path to the bash command you need to execute to read groups. **System Role:** Source	SSH Server (Beta)
`ssh.create.group.command`	Path to the bash command you need to execute to create a group. **System Role:** Source, Target	SSH Server (Beta)
`ssh.update.group.command`	Path to the bash command you need to execute to update a group. **System Role:** Source, Target	SSH Server (Beta)
`ssh.delete.group.command`	Path to the bash command you need to execute to delete a group. **System Role:** Source, Target	SSH Server (Beta)
`ssh.create.user.command.exit.code.already.exists`	An exit code number **System Role:** Source, Target	SSH Server (Beta)
`ssh.update.user.command.exit.code.not.found`	An exit code number **System Role:** Source, Target	SSH Server (Beta)
`ssh.delete.user.command.exit.code.not.found`	An exit code number **System Role:** Source, Target	SSH Server (Beta)
`ssh.create.group.command.exit.code.already.exists`	An exit code number **System Role:** Source, Target	SSH Server (Beta)
`ssh.update.group.command.exit.code.not.found`	An exit code number **System Role:** Source, Target	SSH Server (Beta)

Name	Description	System Type
`ssh.delete.group.command.exit.code.not.found`	An exit code number **System Role:** Source, Target	SSH Server (Beta)
`ssh.auth.type`	Supported SSH authentication types: • *key* • *pwd* • *otp* • *key+otp* • *key+pwd* • *pwd+otp* • *key+pwd+otp* **System Role:** Source, Target	SSH Server (Beta)
`ssh.host`	**System Role:** Source, Target	SSH Server (Beta)
`ssh.port`	**Possible values:** *22* **System Role:** Source, Target	SSH Server (Beta)
`ssh.username`	**System Role:** Source, Target	SSH Server (Beta)
`ssh.password`	(Credential) Taken into account only if the authentication type includes **pwd**. That means any of the following: • `ssh.auth.type` = *pwd* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+pwd+otp* **System Role:** Source, Target	SSH Server (Beta)
`ssh.totp.secret.key`	(Credential) Taken into account only if the authentication type includes **otp**. That means any of the following: • `ssh.auth.type` = *otp* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd+otp* **System Role:** Source, Target	SSH Server (Beta)

Name	Description	System Type
`ssh.private.key`	(Credential) Taken into account only if the authentication type includes **key**. That means any of the following: • `ssh.auth.type` = *key* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *key+pwd+otp* **System Role:** Source, Target	SSH Server (Beta)
`ssh.private.key.type`	The format of SSH private key. **Possible values:** • *ssh-rsa* • *ssh-dsa* Default value: *ssh-rsa* **System Role:** Source, Target	SSH Server (Beta)
`sf.page.size`	Use this property to configure the paging. That means, the number of entities to be read from SAP SuccessFactors at once. Default value: *100* **System Role:** Source, Proxy	SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API)

Name	Description	System Type
`sf.group.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. Use this property to filter dynamic groups from SAP SuccessFactors. The filter obtains values as described in the OData 2.0 syntax, except any statements with attribute `lastModifiedDateTime`. To learn more, see: • OData version 2 → **4.5. Filter System Query Option ($filter)** • SAP SuccessFactors HCM Suite OData API → **DynamicGroup** • syntax, except anySAP SuccessFactors Workforce SCIM API **Possible values:** If your system consumes SAP SuccessFactors Workforce SCIM API, you can filter groups only by `displayName`. For example: *groupType eq 'permission'* **System Role:** Source, Proxy	• SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API) • SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.group.prefix`	This property distinguishes SAP SuccessFactors groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SF_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP SuccessFactors source system and will be provisioned to the target system with the following name pattern: **`SF_<GroupDisplayName>`**. This way SAP SuccessFactors groups in the target system will be distinguished from groups provisioned from other applications. • When **set in the target system**, only groups containing the **SF_** prefix in their display name will be provisioned to SAP SuccessFactors. Groups without this prefix in the display name won't be provisioned. If the property is not set, the SAP SuccessFactors groups will be read and provisioned to the target system with their actual display names. **System Role:** Source, Target	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.user.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. This property takes values as described in the OData version 2 `lastModifiedDateTime`. **⚠ Caution** Attribute `lastModifiedDateTime` is used internally by the Identity Provisioning service, for calculating the delta load from the SAP SuccessFactors system. You must not use it in your filter statements. If you do, your provisioning jobs will fail. **→ Tip** By default, only **active** users are read from SAP SuccessFactors. If you want to filter by another user status, you can set it in the value of this property, using either the *status value* or the *status text* parameters. See: SAP SuccessFactors HCM Suite OData API → **Querying Different Types of Users** **Possible values:** • If your system consumes SAP SuccessFactors Workforce SCIM API, you can use the supported filter attributes described in SAP SuccessFactors Workforce SCIM API For example: *userName eq "Sebastian"* • If your system consumes SAP SuccessFactors HCM Suite OData API, you can only use attributes supported as filterable by this API. See SAP SuccessFactors HCM Suite OData API. Some of these filterable attributes are: `firstName`, `lastName`, `department`, `division`, `jobCode`, `location`, `status`, `userId`, `username`. For example: *division eq 'Manufacturing (MANU)'* **System Role:** Source, Proxy	• SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API) • SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.user.attributes`	The value of this property is a comma-separated list of user attributes that have to be loaded from/to the SAP SuccessFactors system. Default value: *userId,username,status,email,lastName,firstName,lastModifiedDateTime,personKeyNav* SAP SuccessFactors supports a huge amount of user information, which requires a lot of memory processing time and may even lead to time-out errors. That's why we recommend that you keep the default list of attributes, or specify only a few (the most significant attributes) for your provisioning scenario. **Note** If you want to add more attributes, make sure you have added: • the relevant extra attributes to the value of this property, separated by commas • extra mappings for these attributes in the *user* transformation • extra mappings for these attributes in the write transformation of the relevant target system **Note** Always make sure that attribute `lastModifiedDateTime` is in the list. If you don't specify it, the provisioning from/to SAP SuccessFactors will fail. **System Role:** Source, Target, Proxy	SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API)

Name	Description	System Type

`sf.user.attributes.expand`	This property reads/writes additional user data related to *complex (navigation)* attributes, which are specified in the `sf.user.attributes` property.
	
	Default value: *personKeyNav,personKeyNav/userAccountNav*
	
	For example: If you also need to read the *username* of the manager of a company employee, enter the following configuration in the *Properties* tab:
	
	`sf.user.attributes`
	= *username,firstName,lastName,manager/username*
	
	`sf.user.attributes.expand`
	= *personKeyNav,personKeyNav/userAccountNav,manager*
	
	System Role: Source, Target, Proxy
		SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API)

Name	Description	System Type
`aad.user.attributes.expand`	This property allows you to expand the list of attributes specified in the `aad.user.attributes` property with additional user attributes. Once you provide the value of the additional attributes in the `aad.user.attributes.expand` property, you need to extend the read transformation of Microsoft Entra ID with attribute mappings based on the given value. Currently, the read transformation of Microsoft Entra ID is extended with the attribute mappings for manager **id** and **displayName** as follows: Code Syntax `{ "sourcePath": "$.manager.id", "targetPath": "$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']['value']", "optional": true }, { "sourcePath": "$.manager.displayName", "targetPath": "$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']['displayName']", "optional": true }`  To read the manager of the user, you need to provide the manager as a value of the `aad.user.attributes.expand` property in the following format: **`manager($select=id,displayName)`** For more information on the attributes (relationships) that support the **$expand** query parameter, refer to Microsoft Graph REST API v1.0 → *Relationships*. **System Role:** Source, Proxy	Microsoft Entra ID

Name	Description	System Type
`aad.group.attributes.expand`	This property allows you to expand the list of attributes specified in the `aad.group.attributes` property with additional group attributes. Once you provide the value of the additional attributes in the `aad.group.attributes.expand` property, you need to extend the read transformation of Microsoft Entra ID with attribute mappings based on the given value. For more information on the attributes (relationships) that support the **$expand** query parameter, refer to Microsoft Graph REST API v1.0 → *Relationships*. **System Role:** Source, Proxy	Microsoft Entra ID
`RemoteSystemID`	**Note** Only relevant to API **v.1**. Enter the system instance ID, configured for the communication system setting in the SAP Sales Cloud and SAP Service Cloud system. **Possible values:** For example: *IPS* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud
`RecipientPartyID`	**Note** Only relevant to API **v.2**. Enter the recipient system name. **Possible values:** For example: *0011SAP* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`SenderPartyID`	**Note** Only relevant to API **v.2**. Enter the name of the sender system name. It's equal to the value of property `RemoteSystemID` from API v.1. **Possible values:** For example: *IPS* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`TrustAll`	Use this property when you create a connectivity destination in SAP BTP cockpit with authentication type `BasicAuthentication` to configure your provisioning system. Use cases: • If this property is not specified or set to *false*, you need to add a truststore certificate to check for SSL connections. You can either use the default JDK truststore, or provide a custom truststore certificate – if you use a custom domain instead of the default Identity Authentication one. For more information, see: Use Destination Certificates (Cockpit) Use Custom Domain in Identity Authentication • If the property is enabled (set to *true*), the server certificate will be ignored, thus – not checked for SSL connections. → Remember For productive scenarios, we recommend that you do not use this property (or set it to *false*) because the SSL server certificate cannot be verified, and thus the server is not authenticated. Enable the property only for testing purposes. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Source, Target, Proxy	All systems

Name	Description	System Type
`uaa.origin`	It denotes the `origin` attribute in the system transformation. The value of this property is the location of your Cloud Foundry identity provider. If not sure about the value, ask your Cloud Foundry system administrator. **Possible values:** Text/numeric string Source, Target, Proxy	Cloud Foundry UAA Server
`uaa.origin.filter.enabled`	This flag property depends on `uaa.origin`. If the flag is set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `uaa.origin`. **Possible values:** *true* or *false* - If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `uaa.origin`. - If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. - If set to *true* but the `uaa.origin` property is missing, the provisioning job will fail. **System Role:** Source, Proxy	Cloud Foundry UAA Server
`uaa.patch.response.with.resource`	Use this property if you want to retrieve a group whose membership was modified. **Note** This property is usable only when you have configured membership modifications via `Add/Remove Member` UAA endpoints. That is, when the `scim.support.patch.operation` property is set to *false*. **Possible values:** - *true* – the Identity Provisioning service will return the modified group via the `GET /Groups` endpoint of UAA. To learn how, see Retrieve . - *false* – no modified groups will be returned by the service. **System Role:** Proxy	Cloud Foundry UAA Server

Name	Description	System Type
`uaa.group.prefix`	This property distinguishes Cloud Foundry UAA Server groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **UAA_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the Cloud Foundry UAA Server source system and will be provisioned to the target system with the following name pattern: **`UAA_<GroupDisplayName>`**. This way Cloud Foundry UAA Server groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the Cloud Foundry UAA Server groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **UAA_** prefix in their display name will be provisioned to Cloud Foundry UAA Server. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to Cloud Foundry UAA Server. **System Role:** Source and Target	Cloud Foundry UAA Server
`xsuaa.origin`	Holds the identity provider of a user in SAP BTP XS Advanced UAA (Cloud Foundry). You can find it in the SAP BTP cockpit. Go to your Cloud Foundry subaccount, choose *Trust Configuration* and see the value under *Origin Key*. For more information, see Configure Single and Multiple Origins [page 1051] **Possible values:** Text/numeric string For example: *myaccount-xsuaa.accounts.ondemand.com* **System Role:** Source, Target, Proxy	SAP BTP XS Advanced UAA (Cloud Foundry)

Name	Description	System Type
`xsuaa.origin.filter.enabled`	This flag property depends on `xsuaa.origin`. If the flag is set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `xsuaa.origin`. Possible values: *true* or *false* • If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `xsuaa.origin`. • If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. • If set to *true* but the `xsuaa.origin` property is missing, the provisioning job will fail. **System Role:** Source, Proxy	SAP BTP XS Advanced UAA (Cloud Foundry)
`xsuaa.patch.response.with.resource`	Use this property if you want to retrieve a group whose membership was modified. **Note** This property is usable only when you have configured membership modifications via *Add/Remove Member* UAA endpoints. That is, when the `scim.support.patch.operation` property is set to *false*. **Possible values:** • *true* – the Identity Provisioning service will return the modified group via the `GET /Groups` endpoint of UAA. To learn how, see Retrieve . • *false* – no modified groups will be returned by the service. **System Role:** Proxy	SAP BTP XS Advanced UAA (Cloud Foundry)
`workzone.user.filter`	When specified, only those SAP Build Work Zone, advanced edition users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:** Source	SAP Build Work Zone, advanced edition

Name	Description	System Type
`workzone.group.filter`	When specified, only those SAP Build Work Zone, advanced edition groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Build Work Zone, advanced edition
`workzone.group.prefix`	This property distinguishes SAP Build Work Zone, advanced edition groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: WORKZONE_ You can use the example value or provide your own. • When set in the source system, the prefix will be prepended to the name of the groups that are read from the SAP Build Work Zone, advanced edition source system and will be provisioned to the target system with the following name pattern: WORKZONE_GroupDisplayName. This way SAP Build Work Zone, advanced edition groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Build Work Zone, advanced edition groups will be read and provisioned to the target system with their actual display names. • When set in the target system, only groups containing the WORKZONE_ prefix in their display name will be provisioned to SAP Build Work Zone, advanced edition. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Build Work Zone, advanced edition. System Role: Source and Target	SAP Build Work Zone, advanced edition

Name	Description	System Type
`workzone.content.type`	This property makes a SAP Build Work Zone, advanced edition connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Build Work Zone, advanced edition could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Build Work Zone, advanced edition

Name	Description	System Type
`workzone.support.patch.operation`	The default value of this property is *false*. But for SAP Build Work Zone, advanced edition proxy systems, this property appears during creation and its predefined value is *true*. That means, when the Identity Provisioning identifies a changed entity in the back-end system, it will execute the updates as PATCH requests instead of PUT. That is, only changes will be written in SAP Build Work Zone, advanced edition, instead of provisioning the whole entity data. **Additional Information:** There are different cases when an entity should be updated in the target system: • In the source system, some of the entity attributes have been changed, or new attributes have been added. • In the source system, a condition or a filter is set for this entity not to be read anymore. • The whole entity has been deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value for proxy systems: *true* Default value for target systems: *false* **System Role:** Target, Proxy	SAP Build Work Zone, advanced edition

Name	Description	System Type
`workzone.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Build Work Zone, advanced edition. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	SAP Build Work Zone, advanced edition

Name	Description	System Type
`workzone.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Build Work Zone, advanced edition target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. **Possible values:** Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: `displayName` **System Role:** Target	SAP Build Work Zone, advanced edition
`fsm.group.filter`	When specified, only those SAP Field Service Management groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Field Service Management
`fsm.user.filter`	When specified, only those SAP Field Service Management users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:** Source, Proxy	SAP Field Service Management
`fsm.content.type`	This property makes the SAP Field Service Management connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Field Service Management could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Field Service Management

Name	Description	System Type
`fsm.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP Field Service Management target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: `displayName`. **System Role:** Target	SAP Field Service Management
`fsm.include.if.match.wildcard.header`	Makes the SAP Field Service Management connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Field Service Management system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Field Service Management

Name	Description	System Type
`fsm.support.patch.operation`	The default value of this property is *false*. But for SAP Field Service Management proxy systems, this property appears during creation and its predefined value is *true*. That means, when the Identity Provisioning identifies a changed entity in the back-end system, it will execute the updates as PATCH requests instead of PUT. That is, only changes will be written in SAP Field Service Management, instead of provisioning the whole entity data. Note that only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". **Possible values:** Default value: *false* Predefined value (during system creation): *true* **System Role:** Target, Proxy	SAP Field Service Management

Name	Description	System Type
`fsm.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Field Service Management. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* Default value: *userName* **System Role:** Target	SAP Field Service Management

Name	Description	System Type
`ias.api.version`	Defines the version of Identity Authentication SCIM API. **Possible values:** • *1* - Identity Authentication SCIM API is used. • *2* - Identity Directory SCIM API is used. Default value: *2* **System Role:** Source, Target, Proxy	Identity Authentication

Name	Description	System Type
`ias.user.filter`	This property filters users by attributes from the SCIM core schema, the Enterprise user resource schema and the Custom defined schema. For example: `userName`, `emails.value`, `addresses.country`, `employeeNumber`, `costCenter`, `department` and others. For more information on the attributes defined in the SCIM core schema and the Enterprise user resource schema, see Identity Directory Service Schema View You can set a single attribute or multiple ones as search criteria in the following value pattern: Single attribute: *<user_attribute> eq "<value>"* Multiple attributes: *<user_attribute1> eq "<value1>" and/or <user_attribute2> eq "<value2>"* **Possible values:** For example: • Single attribute: *userName eq "Sebastian"* • Multiple attributes (with **OR**): *userName eq "Sebastian" or addresses.country eq "France"* • Multiple attributes (with **AND**): *userName eq "Sebastian" and addresses.country eq "France"* • Multiple attributes (with brackets): *userName eq "Sebastian" or (addresses.country eq "France" and emails.value eq "sebastian123@mail.com")* • Multiple attributes (enterprise attributes): *urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:department eq "Dev" and urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:organization eq "Technology"* **System Role:** Source, Proxy	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`ias.group.filter`	This property filters groups by display name. You can set a single display name or multiple ones as filter criteria. If you enter multiple display names (using **OR** operator), the filter will search for any of them. Single attribute: *displayName eq "<group_name>"* Multiple attributes: *displayName eq "<group_name1>" or displayName eq "<group_name2>"* **Possible values:** For example: • Single attribute: *displayName eq "FellowshipTeam1"* • Multiple attributes: *displayName eq "FellowshipTeam1" or displayName eq "JuniorTest3"* **System Role:** Source, Proxy	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`ias.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with "scope": "createEntity", such as: `{ "constant":true, "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']", "scope":"createEntity" }` • If set to *false*, Identity Provisioning sends a PUT request to the user or group resource in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Users and groups can be updated in the target system in various cases, such as: • In the source system, some user or group attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users or groups not to be read anymore. • A user or a group is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**.	Identity Authentication (SCIM API version 2)

Name	Description	System Type
	Possible values: • *true* • *false* Default value: *false* **System Role:** Target, Proxy	
`ias.user.groups.paging.enabled`	This property enables paging of user's groups. The maximum number of user's groups returned per request is 1 000. To read more than 1 000 user's groups, paging must be enabled. **Possible values:** • *true* - Paging is enabled. You can read more than 1 000 user's groups in one request. • *false* - Paging is disabled. You can read up to 1 000 user's groups in one request. Default value: *false* **System Role:** Source, Proxy	Identity Authentication (SCIM API version 2)
`ias.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 20 000. To read more than 20 000 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. You can read more than 20 000 group members in one request. • *false* - Paging is disabled. You can read up to 20 000 group members in one request. Default value: *false* **System Role:** Source, Proxy	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`ias.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`ias.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. **If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find a user on the target system via this filter, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is set during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *phoneNumbers[0].value*. If the service finds an existing user with such *phoneNumber*, it updates this user with the data of the conflicting one. If a user with such *phoneNumber* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, phoneNumbers[0].value*. If the service finds an existing user with both these *userName* and *phoneNumber*, it updates this user with the data of the conflicting one. If such a user is not found, that	Identity Authentication (SCIM API version 2)

Name	Description	System Type
	means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, emails[0].value, phoneNumbers[0].value*. If the service finds an existing user with these *userName*, *email* and *phoneNumber*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *phoneNumbers[0].value* • *userName, phoneNumbers[0].value* • *userName, emails[0].value, phoneNumbers[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	

Name	Description	System Type
`ias.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In such cases, the existing group only needs to be updated. This property defines the unique attribute(s) by which the existing group will be searched and resolved. The default value is *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']*. When set, you can expect the following behavior: • If a group with the given *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* is found in the target system, the group that you try to provision will overwrite the existing one. • If a group with the given *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* is not found in the target system, the group that you try to provision will not be created in the target system. In scenarios where groups are provisioned from SAP Integrated Business Planning version 2 and SAP S/4HANA Cloud Public Edition version 3, the uniqueness of the group is resolved by a combination of three attributes: *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],* *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],* *['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']* For the conflict to be resolved, an existing group must match all three attributes. If the property is not specified, the search is done by the default attribute: *['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']* **System Role:** Target	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`ias.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	Identity Authentication (SCIM API version 2)

Name	Description	System Type
`aad.user.filter.group.filter.combine`	Filters Microsoft Entra ID users based on their group assignments. When set to *true*, this property combines user and group filters defined on the `aad.user.filter` and `aad.group.filter` properties to further narrow the search results. This way, only users that meet the following filtering criteria are returned: • Users that match the user filter and at the same time are members of groups that match the group filter. • Members of the filtered groups that match the user filter. **Note** To make the `aad.user.filter.group.filter.combine` property work, ensure that both user and group entities are read, that is, neither of them is ignored in the transformation code. **Example** 1. You have the following users, located in two cities with one or more assigned groups: **User**: David Thompson from London with assigned **Groups**: Marketing and Sales **User**: Julie Armstrong from New York with assigned **Groups**: Employee **User**: John Smith from New York with assigned **Groups**: Marketing and Sales 2. You have defined the following filtering criteria: `aad.user.filter` = *city eq "New York"* `aad.group.filter` = *displayName eq “Marketing”* `aad.user.filter.group.filter.combine` = *true* 3. You get the following result: Only user John Smith is returned as it matches	Microsoft Entra ID

Name	Description	System Type
	the user filter and at the same time is a member of the group that matches the group filter. Although David Thompson matches the group filter, he doesn't match the user filter. Although Julie Armstrong matches the user filter, shed doesn't match the group filter. When set to *false*, user and group filters are not combined. For more information, see: Identity Provisioning: How to Get Users Based on Group Assignments from MS Entra ID **Possible values:** • *true* When this property is set to **true**, it is expected that filtering criteria are defined for `aad.user.filter` and `aad.group.filter` properties. If one or both are not defined in the UI, be aware of the following behavior: • Only `aad.user.filter` is defined: Users that match the user filter and are members of any group will be returned. If a user matches the user filter but is not a member of any group, this user will not be returned. • Only `aad.group.filter` is defined: Users that are members of the groups matching the group filter will be returned. • None of the properties are defined: Users that are members of any group will be returned. When this property is set to *true* and filtering criteria are defined for `aad.user.filter` and `aad.group.filter` properties, if you are searching for a specific user or group using Identity Provisioning service API, be aware of the following behavior: • When searching for specific user with `GET .../Users/UserId` request,	

Name	Description	System Type
	filtering criteria defined on both properties are not considered. The user is returned with all the groups he or she is a member of. • When searching for specific group with `GET ...Groups/GroupId` request, filtering criteria defined on both properties are not considered. The group is returned with all its group members. • *false* - default value **System Role**: Source, Proxy	
`s4hana.pp.user.filter`	When specified, only those SAP S/4HANA for procurement planning users matching the filter expression will be read. **Possible values:** Example: *name.familyName eq "Smith" and addresses.country eq "US"* **System Role:** Source, Proxy	SAP S/4HANA for procurement planning
`s4hana.pp.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP S/4HANA for procurement planning
`s4hana.pp.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP S/4HANA for procurement planning

Name	Description	System Type
`s4hana.pp.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	SAP S/4HANA for procurement planning

Name	Description	System Type

`ias.user.automatic.conflict.resolution`	Controls whether automatic conflict resolution is switched on or off in Identity Authentication (target system) when provisioning is triggered from source systems containing different users with the same user identifiers (IDs).
	
	For example, when SAP SuccessFactors and SAP SuccessFactors Learning are configured as source systems for provisioning users to Identity Authentication, it could happen that different SAP SuccessFactors and SAP SuccessFactors Learning users have the same user IDs. In this case, when the first user is created in Identity Authentication, after triggering a provisioning job, the second (conflicting) user will either overwrite the already existing one (automatic conflict resolution is switched on) or will fail and won't be created (automatic conflict resolution is switched off).
	
	To control this behavior, you can use the `ias.user.automatic.conflict.resolution` property in the target Identity Authentication system. This property is not added by default.
	
	Possible values:
	
	• *true* - If the property is set to true, or is not set at all, the automatic conflict resolution is switched on. This means that Identity Provisioning takes into account the unique attribute(s) defined on the `scim.user.unique.attribute` property (when using SCIM API version 1) or `ias.user.unique.attribute` property (when using SCIM API version 2) and tries to find an already existing user in Identity Authentication matching these attributes.
	  • If a user is found, the provisioning of a new (conflicting) user is resolved as follows: the conflicting user overwrites the existing one.
	  • If a user is not found, the provisioning of a conflicting user fails, and it is not created in Identity Authentication.
		Identity Authentication

Name	Description	System Type
	• *false* - If the property is set to false, the automatic conflict resolution is switched off. This means that Identity Provisioning does not take into account the unique attribute(s) defined on the `scim.user.unique.attribute` property (when using SCIM API version 1) or `ias.user.unique.attribute` property (when using SCIM API version 2) and fails the provisioning of a conflicting user. This user is not created in Identity Authentication and does not overwrite the existing one. In the Job Log, an error code `409, uniqueness` will be displayed. Default value: *true* **System Role:** Target	

Name	Description	System Type
`ias.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when Identity Authentication is based on Identity Directory SCIM API (in short, SCIM API version 2). **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the Identity Authentication target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will	Identity Authentication

Name	Description	System Type
	be sent to the Identity Authentication target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in Identity Authentication, the maximum number of members which can be removed per one **PATCH** request is 50. **System Role:** Target	

Name	Description	System Type
`idds.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when Identity Authentication and Identity Provisioning (where Local Identity Directory is configured), are running on the same infrastructure, that is, the infrastructure of Identity Authentication. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the Local Identity Directory target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by add-	Local Identity Directory

Name	Description	System Type
	ing another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 **PUT** request with 800 group members will be sent to the Local Identity Directory target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in Local Identity Directory, the maximum number of members which can be removed per one **PATCH** request is 50. **System Role:** Target	

Name	Description	System Type
`xsuaa.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1 900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the XSUAA target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the XSUAA target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members.	SAP BTP XS Advanced UAA (Cloud Foundry)

Name	Description	System Type
	System Role: Target	

Name	Description	System Type
`ias.user.update.instead.delete`	When using SCIM API version 2, this property allows you to update user attributes with PATCH request in Identity Authentication target system and to preserve the user record instead of deleting it. This behavior is supported only when the scope of the attribute is set to **deleteEntity**. In addition to configuring this property, you also need to adapt the write transformation. For example, if you want to disable a user account in Identity Authentication, you need to do the following: 1. Set `ias.user.update.instead.delete` =*true* 2. Adapt the write transformation as follows: `{ "user":{ "mappings":[{ "constant":"urn:ietf:params:scim:api:messages:2.0:PatchOp", "targetPath":"$.schemas[0]", "scope":"deleteEntity" }, { "constant":"replace", "targetPath":"$.Operations[0].op", "scope":"deleteEntity" }, { "constant":"active", "targetPath":"$.Operations[0].path", "scope":"deleteEntity" }, { "constant":false, "targetPath":"$.Operations[0].value", "scope":"deleteEntity"`	Identity Authentication

Name	Description	System Type

```
            },
...
```

In this case, the PATCH operation will replace *true* with *false* as the value of the `active` user attribute. As a result, when the PATCH operation is executed, the user record in the target system will no longer be managed by Identity Provisioning as it is considered deleted.

For more information, see: Transformation Expressions [page 391] → *Scope* → *deleteEntity* → *Identity Authentication (SCIM API version 2)*

Possible values:

- *true*
- *false*

Default value: *false*

When the property is set to *true*, adapt the write transformation with the attribute name and the attribute value you want to update:

```
{
   "user":{
      "mappings":[
         {

"constant":"urn:ietf:params:sci
m:api:messages:2.0:PatchOp",

"targetPath":"$.schemas[0]",

"scope":"deleteEntity"
         },
         {

"constant":"replace",

"targetPath":"$.Operations[0].o
p",

"scope":"deleteEntity"
         },
         {

"constant":"<attribute_name>",

"targetPath":"$.Operations[0].p
ath",

"scope":"deleteEntity"
         },
         {

"constant":<attribute_value>,
```

Name	Description	System Type

	<pre>"targetPath":"$.Operations[0].value",
	"scope":"deleteEntity"
	},
	...</pre>
	System Role: Target	

`lms.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** • *userName eq "testName"* • *externalID eq "testID"* • *active eq "true"* • *sourceSystem eq "Learning"* - indicates that the user is created directly in SAP SuccessFactors Learning with no involvement of Identity Provisioning. • *sourceSystem eq "Identity Provisioning"* - indicates that the user is created in SAP SuccessFactors Learning by Identity Provisioning. **System Role:** Source	SAP SuccessFactors Learning
`lms.content.type`	This property makes the SAP SuccessFactors Learning connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP SuccessFactors Learning could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP SuccessFactors Learning

Name	Description	System Type
`lms.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that such user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). If the service finds such user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find such a user, the creation will fail. **Default behavior**: The property is missing during system creation. Its default value is *userName*. This means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. **Possible values:** Default value: *userName* **System Role:** Target	SAP SuccessFactors Learning
`lms.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* **System Role:** Target, Proxy	SAP SuccessFactors Learning

Name	Description	System Type
`lms.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP SuccessFactors Learning

Name	Description	System Type
`lms.instance.host`	Enter the host of your SAP SuccessFactors Learning instance. This property must be configured if you what to use client certificate authentication for the communication between Identity Provisioning and SAP SuccessFactors Learning. **System Role:** Source, Target, Proxy	SAP SuccessFactors Learning
`ias.support.bulk.operation`	This property enables bulk operations for users and groups. When bulk operations are enabled, Identity Provisioning creates, updates, and deletes multiple users and groups in one request. When bulk operations are not enabled, Identity Provisioning creates, updates, and deletes one user at a time. For more information, see: Identity Directory SCIM API. **Possible values:** • *true* - bulk operations are enabled • *false* - bulk operations are not enabled Default value: *false* **System Role:** Target	Identity Authentication (using SCIM API version 2)
`ias.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, Identity Provisioning will replace it with the default value (20). **System Role:** Target	Identity Authentication (using SCIM API version 2)

Name	Description	System Type
`idds.support.bulk.operation`	This property enables bulk operations for users and groups. When bulk operations are enabled, Identity Provisioning creates, updates, and deletes multiple users and groups in one request. When bulk operations are not enabled, Identity Provisioning creates, updates, and deletes one user at a time. For more information, see: Identity Directory SCIM API. **Possible values:** • *true* - bulk operations are enabled • *false* - bulk operations are not enabled Default value: *false* **System Role:** Target	Local Identity Directory
`idds.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, Identity Provisioning will replace it with the default value (20). **System Role:** Target	Local Identity Directory

Name	Description	System Type
`concur.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** Examples when SAP Concur connector is configured for version 2: • *userName eq "johnsmith@example.com"* As the userName must be unique across SAP Concur, this filter returns only the user matching this userName. • *companyId eq "aa067ada-71a9-4f57-8e98-9300b1c3171d"* This filter returns all users in the company with this companyId. • *externalId eq "0fe44868-31a7-4930-9ah30-757tg2513b64"* This filter returns a user with the specified value, that is, the userUUID generated for the user in Identity Authentication. • *employeeNumber eq "Concur Administrator"* This filter returns a user with the specified employee number. The employeeNumber could also be a number having six or more digits. Examples when SAP Concur connector is configured for version 3: • *userName eq "JohnSmith"* • *userName sw "John"* • *externalId eq "0fe44868-31a7-4930-9ah30-757tg2513b64"* • *urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber eq "00102345"* **System Role:** Source, Proxy	SAP Concur (using SAP Concur Identity v4 API)

Name	Description	System Type
`concur.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP Concur (using SAP Concur Identity v4 API)
`concur.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Concur (using SAP Concur Identity v4 API)

Name	Description	System Type
`concur.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. You can set any combination of the supported unique attributes, separated by commas: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value=*userName,urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber*. If the service finds an existing user with both these userName and employeeNumber, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values** for version 2: • *userName* • *externalId* or another SCIM attribute, or a conjunction of SCIM attributes **Possible values** for version 3: • *userName* • *externalId* • *urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber* Default value: *userName* **System Role:** Target	SAP Concur (using SAP Concur Identity v4 API and SAP Concur SCIM API)

Name	Description	System Type
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 **System Role:** Source, Target, Proxy	SAP Concur
`concur.api.version`	Defines the version of SAP Concur API. **Possible values:** • *1* - User v1 API is used. • *2* - Identity v4 API is used. • *3* - SCIM v4 API is used. Default value: *3* **System Role:** Source, Target, Proxy	SAP Concur

Name	Description	System Type
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token. The Company Request Token is generated in the SAP Concur Company Request Token self-service tool. **System Role:** Source, Target, Proxy	SAP Concur
`concur.company.id`	Your company UUID The Company ID is generated in the SAP Concur Company Request Token self-service tool. **System Role:** Target, Proxy	SAP Concur

Name	Description	System Type
`concur.company.domain`	Your company domain The username and the company domain are concatenated in the SAP Concur default transformations in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: *johnsmith@example.com* **System Role:** Target, Proxy	SAP Concur
`ariba.applications.patch.group.members.of.nested.groups`	If you set this property to *true*, Identity Provisioning will update only user members of a group in SAP Ariba Applications target system. The update will be executed on batches via PATCH requests. This will preserve the group hierarchy with nested groups in the SAP Ariba Applications backend. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Ariba Applications

Name	Description	System Type
`ariba.applications.patch.group.members.above.threshold`	This property is relevant only when `ariba.applications.patch.group.members.of.nested.groups` is set to *true*. It defines the maximum number of user members of a group that are included in one PATCH request. If the maximum value of 200 000 is exceeded, the system sets automatically the default value. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *50* Minimum value: *1* Maximum value: *50* **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **System Role:** Target	SAP Ariba Applications
`cflp.providerId`	Your SAP Build Work Zone, standard edition provider ID The provider ID is specified in the Channel Manager of theSAP Build Work Zone, standard edition when defining a new content provider. For more information about configuring the content provider to use the Identity Provisioning service, see Configure Integration with the Identity Provisioning Service **Possible values:** The value of your SAP Build Work Zone, standard edition provider ID For example: *ABC123* **System Role:** Target, Proxy	SAP Build Work Zone, standard edition

Name	Description	System Type
`cflp.user.filter`	When specified, only those SAP Build Work Zone, standard edition users matching the filter expression will be read. By default, users are always filtered by the *providerId*. If another filtering attribute is defined, for example the email of the user, both filters are combined. **Possible values:** • *emails.value eq "john.smith@example.com"* > **Note** > Although, the email is supported as a filtering attribute, it is not returned when searching for the user. • *urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq "ABC123"* Combining filter attributes is allowed using the and operator, for example: *emails.value eq "john.smith@example.com" and urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq "ABC123"* **System Role:** Proxy	SAP Build Work Zone, standard edition
`cflp.group.filter`	When specified, only those SAP Build Work Zone, standard edition groups matching the filter expression will be read. By default, groups are always filtered by the *providerId*. **Possible values:** • *externalId eq 12345678* • *urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq 'ABC123'* • *meta.isIAG eq true* This filtering attribute indicates whether the group will be used in a hybrid scenario with SAP Cloud Identity Access Governance. **System Role:** Proxy	SAP Build Work Zone, standard edition

Name	Description	System Type
`cflp.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. **Possible values:** SAP Build Work Zone, standard edition supports the following unique attributes which are automatically filled in when the target system is added in the service UI: **`emails[0].value, ['urn:ietf:params:scim:schemas:extension:2.0:mapping'] ['providerId'],externalId`** **Note** SAP Build Work Zone, standard edition, only supports **`externalId`** of type UUID. - If the user has an **`externalId`**, the conflict is resolved by **`externalId`** and **`providerId`**. - If the user doesn't have an **`externalId`**, the conflict is resolved by **`email`** and **`providerId`**. For the conflict to be resolved, an existing user matching both unique attributes should be found. Whether the existing user will be updated or a new one will be created by Identity Provisioning depends on the following conditions - was the user created by the Identity Provisioning service, what combination of unique attributes exist for the user, and has any of the provisioning systems (source or target) been reset. For more information, see Step 4 of the relevant SAP Build Work Zone, standard edition documentation. **→ Recommendation** We recommend that you do not modify the value of the `cflp.user.unique.attribute` property. Otherwise, user creation fails.	SAP Build Work Zone, standard edition

Name	Description	System Type
	System Role: Target	
`cflp.group.unique.attribute`	If Identity Provisioning tries to provision a group that already exists in the target system (a conflicting group), this property defines the unique attributes by which the existing group will be searched and resolved. **Possible values:** SAP Build Work Zone, standard edition supports a pair of unique attributes which is automatically filled in when the target system is added in the service UI: *externalId, ['urn:ietf:params:scim:schemas:extension:2.0:mapping']['providerId']* For the conflict to be resolved, an existing group matching both unique attributes should be found. In this case, Identity Provisioning updates the group. This means, the conflicting group overwrites the existing one. If the group matches only one of the unique attributes, the conflict is not resolved, and the group creation fails. → Recommendation We recommend that you do not modify the value of the `cflp.group.unique.attribute` property. Otherwise, the group creation fails. **System Role:** Target	SAP Build Work Zone, standard edition

Name	Description	System Type
`cflp.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values:** integer Default and maximum value: *5000* Minimum value: *1* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1 900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Build Work Zone, standard edition target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP Build Work Zone, standard edition target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members.	SAP Build Work Zone, standard edition

Name	Description	System Type
	Note If the maximum value of *5000* is exceeded, the system will automatically use the default value. **System Role:** Target	
`cflp.support.bulk.operation`	This property enables bulk operations for users and groups. When the property is enabled (set to *true*), the following operations can be executed by Identity Provisioning service in a single request: • Create or delete multiple users • Create, update, or delete multiple groups When the property is disabled (set to *false*), the following operations can be executed by Identity Provisioning service for a single entity at a time: • Create or delete a user • Create, update, or delete a group **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Build Work Zone, standard edition
`cflp.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP Build Work Zone, standard edition

Name	Description	System Type
`xsuaa.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find such a user, the creation will fail. According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both attributes: *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,origin*. If the service finds an existing user with both attributes: *userName* and *origin*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value*	SAP BTP XS Advanced UAA (Cloud Foundry)

Name	Description	System Type
	• *userName,emails[0].value* • *userName,origin* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	
`fsm.group.prefix`	This property distinguishes SAP Field Service Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`FSM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Field Service Management source system and will be provisioned to the target system with the following name pattern: **`FSM_<GroupDisplayName>`**. This way SAP Field Service Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Field Service Management groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`FSM_`** prefix in their display name will be provisioned to SAP Field Service Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Field Service Management. **System Role:** Source and Target	SAP Field Service Management

Name	Description	System Type
`sf.user.read.deactivatedafter`	This property filters SAP SuccessFactors inactive users from a particular date on. It is an optional property which does not appear by default at system creation. It accepts a value in the **`yyyy-MM-dd`** format. For example: **`2023-07-17`** The `sf.user.read.deactivatedafter` property is supported for SAP SuccessFactors version 2 using SAP SuccessFactors Workforce SCIM API. It works together with the `sf.user.filter` property which is added at system creation with the default value: *active eq true*. Using it can further narrow down the filtering results. To filter active users along with inactive ones from a particular date on, the following configuration must be in place: • Set the `sf.user.read.deactivatedafter` value to a date in the expected format. For example: *2023-07-17* • `sf.user.filter` = *active eq true* As a result, Identity Provisioning reads SAP SuccessFactors active users and the users set to inactive from that date on using the 2023-07-17T00:00:00Z date-time format. Depending on the value you define for `sf.user.filter`, expect the following results: • `sf.user.filter` = *active eq false* All inactive users will be returned. • `sf.user.filter` = *active eq false and userName sw "Test_"* All inactive users with username starting with Test_ will be returned. **Note** When you filter by `sf.user.filter` = *active eq false* along with the property `sf.user.read.deactivatedafter`, the users that match the two critera will be read twice.	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
	• `sf.user.filter` = *active eq true and userName sw "Test_"* Inactive users from the provided date on and all active users with username starting with Test_ will be returned. **System Role:** Source, Proxy	
`cc.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails.value`**, and **`externalId`**, according to the API syntax of SAP Commerce Cloud. **Possible values:** text/ numeric string For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "P000252"* > **Note** > These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP Commerce Cloud
`cc.group.filter`	When specified, only those groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1" or "Students2018"* **System Role:** Source, Proxy	SAP Commerce Cloud

Name	Description	System Type
`cc.group.prefix`	This property distinguishes SAP Commerce Cloud groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Commerce Cloud source system and will be provisioned to the target system with the following name pattern: **`CC_<GroupDisplayName>`**. This way SAP Commerce Cloud groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Commerce Cloud groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`CC_`** prefix in their display name will be provisioned to SAP Commerce Cloud. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Commerce Cloud. **System Role:** Source, Target	SAP Commerce Cloud

Name	Description	System Type
`cc.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Note** When executing a remove operation, all members of a group are removed without considering the number of deleted group members in the source system. **Additional Information:** There are different cases when an entity should be updated in the target system: • In the source system, some of the entity attributes have been changed, or new attributes have been added. • In the source system, a condition or a filter is set for this entity not to be read anymore. • The whole entity has been deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of	SAP Commerce Cloud

Name	Description	System Type
	your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value for proxy systems: *true* Default value for target systems: *false* **System Role:** Proxy, Target	
`cc.include.if.match.wildcard.header`	Makes the SAP Commerce Cloud connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Commerce Cloud system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Commerce Cloud

Name	Description	System Type
`cc.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In this case, the existing group only needs to be updated. This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is *displayName*. Currently, it is the only unique attribute that is supported. When set, you can expect the following behavior: • If a group with the given *displayName* is found in the target system, the group that you try to provision will overwrite the existing one. • If a group with the given *displayName* is not found in the target system, the group that you try to provision will not be created in the target system. If the property is not specified, the search is done by the default attribute: `displayName` **System Role:** Target	SAP Commerce Cloud

Name	Description	System Type
`cc.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find such a user, the creation will fail. The property is automatically added during system creation. If the service finds an existing user by at least one of the uniqueness criteria, which are *email*, *userName*, or *externalId*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the update of the conflicting user fails. If more than one users with these unique attributes are found, the update fails. **Possible values:***emails[0].value, userName, externalId* Default value: *emails[0].value, userName, externalId* **System Role:** Target	SAP Commerce Cloud
`cc.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP Commerce Cloud

Name	Description	System Type
`cc.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when SAP Commerce Cloud is based on SAP Commerce Cloud SCIM API (in short, SCIM API version 2). **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Commerce Cloud target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be	SAP Commerce Cloud

Name	Description	System Type
	sent to the SAP Commerce Cloud target system to update the group. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in SAP Commerce Cloud, the maximum number of members which can be removed per one **PATCH** request is 98. **System Role:** Target	
`cc.patch.group.members.of.nested.groups`	If you set this property to *true*, Identity Provisioning will update only user members of a group in SAP Commerce Cloud target system. The update will be executed on batches via PATCH requests. This will preserve the group hierarchy with nested groups in the SAP Commerce Cloud backend. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Commerce Cloud

Name	Description	System Type
`maco.roles.prefix`	This property distinguishes SAP Market Communication for Utilities roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SMC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP Market Communication for Utilities source system and will be provisioned to the target system with the following name pattern: **`SMC_<role_name>`** . This way SAP Market Communication for Utilities roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Market Communication for Utilities roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **`SMC_`** prefix in their role name will be provisioned to SAP Market Communication for Utilities. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be provisioned to SAP Market Communication for Utilities. **System Role:** Source and Target	SAP Market Communication for Utilities

Name	Description	System Type
`maco.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Market Communication for Utilities target or proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Possible values:** • *true* – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • *false* – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* **System Role:** Target, Proxy	SAP Market Communication for Utilities
`maco.roles.filter`	Enter OData filtering for reading roles in the SAP Market Communication for Utilities system. To learn what criteria you can use, see: OData URI Conventions → 4.5 Filter System Query Option **System Role:** Source, Proxy	SAP Market Communication for Utilities
`maco.roles.page.size`	This property indicates how many business roles (considered as *groups*) per page to be read from your SAP Market Communication for Utilities source system. **Possible values:** Integer number For example, if you set the property's value = *30*, the Identity Provisioning will read 30 roles (groups) at once, then – another 30, and so on. **System Role:** Source, Proxy	SAP Market Communication for Utilities

Name	Description	System Type
`maco.skip.read.archived`	In the event of archived (disabled) entities in a source SAP Market Communication for Utilities system, you can choose whether the provisioning jobs to continue reading such entities or to skip them. In the source systems, this property is activated by default. If you want to always read disabled entities, set the property to *false*, or delete it. **Possible values:** • *true* • *false* Default value: *true* **System Role:** Source, Target, Proxy	SAP Market Communication for Utilities
`maco.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Market Communication for Utilities
`maco.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20). **System Role:** Target	SAP Market Communication for Utilities

Name	Description	System Type
`sf.api.version`	Handles the version of the API which is consumed by the SAP SuccessFactors system. **Possible values:** • *1* - SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. • *2* - SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used. Default value: *1* **System Role:** Source, Target, Proxy	• SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API) • SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)
`sf.company.id`	Enter the Company ID of your SAP SuccessFactors system. The Company ID is a short string of characters that identifies each SAP SuccessFactors system. It is like a username for your organization. All users of the same system share the same Company ID. This property must be configured if you what to use client certificate authentication for the communication between Identity Provisioning and SAP SuccessFactors. **System Role:** Source, Target, Proxy	• SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API) • SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a `PATCH` request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, `PUT` operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. **Note** Updating the user attributes: `name` and `manager`, is not supported with PATCH operation. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false*	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
	System Role: Target	
`sf.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* **System Role:** Target, Proxy	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)
`sf.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `sf.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **System Role:** Target	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sf.content.type`	This property makes the SAP SuccessFactors connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP SuccessFactors could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP SuccessFactors (using version 1 - SAP SuccessFactors HCM Suite OData API)

Name	Description	System Type
`sf.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when SAP SuccessFactors is based on SAP SuccessFactors Workforce SCIM API (in short, SCIM API). **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1 900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP SuccessFactors target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP SuccessFactors target system to update the group.	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
	Note If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **System Role:** Target	
`sf.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 100. To read more than 100 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **System Role:** Source, Proxy	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)
`sf.patch.group.members.of.nested.groups`	If you set this property to *true*, Identity Provisioning will update only user members of a group in SAP SuccessFactors target system. The update will be executed on batches via PATCH requests. This will preserve the group hierarchy with nested groups in the SAP SuccessFactors backend. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP SuccessFactors (using version 2 - SAP SuccessFactors Workforce SCIM API)

Name	Description	System Type
`sac.group.prefix`	This property distinguishes SAP Analytics Cloud groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SAC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Analytics Cloud source system and will be provisioned to the target system with the following name pattern: **`SAC_<GroupDisplayName>`**. This way SAP Analytics Cloud groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Analytics Cloud groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`SAC_`** prefix in their display name will be provisioned to SAP Analytics Cloud. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Analytics Cloud. **System Role:** Source and Target	SAP Analytics Cloud

Name	Description	System Type
`cpq.group.prefix`	This property distinguishes SAP CPQ groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CPQ_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP CPQ source system and will be provisioned to the target system with the following name pattern: **`CPQ_<GroupDisplayName>`**. This way SAP CPQ groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP CPQ groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`CPQ_`** prefix in their display name will be provisioned to SAP CPQ. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP CPQ. **System Role:** Source and Target	SAP CPQ
`cpq.group.members.paging.enabled`	This property enables the complete retrieval of group members through additional sequential requests. The maximum number of group members returned per request is 100 as defined in `cpq.group.members.page.size`. For more information, see `cpq.group.members.page.size`. Possible Values: • *true* - Paging is enabled. • *false* - Paging is disabled. Default Value: *true* **System Role:** Source, Proxy	SAP CPQ

Name	Description	System Type
`cpq.group.members.page.size`	When the `cpq.group.members.paging.enabled` property is set to true, this setting defines the size of the paged members request. **Note** If you configure `cpq.group.members.page.size` to a number greater than the default value, the complete member retrieval is disabled. Default Value: *100* The number of group members that SAP CPQ returns per request when reading a group. **System Role:** Source, Proxy	SAP CPQ
`cpq.user.filter`	When specified, only those SAP CPQ users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"** **System Role:** Source, Proxy	SAP CPQ

Name	Description	System Type
`scp.group.prefix`	This property distinguishes SAP BTP Account Members (Neo) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SCP_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP BTP Account Members (Neo) source system and will be provisioned to the target system with the following name pattern: **`SCP_<GroupDisplayName>`**. This way SAP BTP Account Members (Neo) groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP BTP Account Members (Neo) groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`SCP_`** prefix in their display name will be provisioned to SAP BTP Account Members (Neo). Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP BTP Account Members (Neo). **System Role:** Source and Target	SAP BTP Account Members (Neo)

Name	Description	System Type
`c4c.user.filter`	When specified, only those SAP Sales Cloud and SAP Service Cloud, formerly known as SAP Cloud for Customer (in short, C4C) users matching the filter expression will be read. Supported user filters in connector version 4: • userName eq "Smith" • userName sw "Sm" • userName eq "Smith" and emails.value eq "smith@example.com" Supported user filter in connector version 3: • addresses.country eq "USA" **System Role:** Source, Proxy	SAP Sales Cloud and SAP Service Cloud
`c4c.group.filter`	When specified, only those SAP Sales Cloud and SAP Service Cloud groups matching the filter expression will be read. SAP Sales Cloud and SAP Service Cloud is formerly known as SAP Cloud for Customer (in short, C4C). Example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`c4c.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *1000* Minimum value: *1* Maximum value: *1000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1 900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Sales Cloud and SAP Service Cloud target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group member changes processed per batch. • PUT request: If you have a group with 1 000 members and the threshold is not set or its value is above *1000*, one PUT request will be sent to SAP Sales Cloud and SAP Service Cloud. But if you set the threshold to 500, 2 PATCH requests will be sent instead, each adding 500 members. **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members.	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
	Note If the maximum value of *1000* is exceeded, the system will automatically use the default value. **System Role:** Target	
`xsuaa.group.prefix`	This property distinguishes SAP BTP XS Advanced UAA (Cloud Foundry) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **XSUAA_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP BTP XS Advanced UAA (Cloud Foundry) source system and will be provisioned to the target system with the following name pattern: **`XSUAA_<GroupDisplayName>`**. This way SAP BTP XS Advanced UAA (Cloud Foundry) groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP BTP XS Advanced UAA (Cloud Foundry) groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **XSUAA_** prefix in their display name will be provisioned to SAP BTP XS Advanced UAA (Cloud Foundry). Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP BTP XS Advanced UAA (Cloud Foundry). **System Role:** Source and Target	SAP BTP XS Advanced UAA (Cloud Foundry)

Name	Description	System Type
`cflp.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Note** Updating users and groups returns 404 Not Found. Users and groups can be updated in the target system in various cases, such as: • In the source system, some user or group attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users or groups not to be read anymore. • A user or a group is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**.	SAP Build Work Zone, standard edition

Name	Description	System Type
	Possible values: • *true* • *false* Default value for proxy systems: *true* Default value for target systems: *false* **System Role:** Target, Proxy	
`sac.api.version`	Defines the version of SAP Analytics Cloud SCIM API. **Possible values:** • *1* - SAP Analytics Cloud SCIM API version 1 is used. • *2* - SAP Analytics Cloud SCIM API version 2 is used. Default value: *1* **System Role:** Source, Target, Proxy	SAP Analytics Cloud

Name	Description	System Type
`sac.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. - If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. - If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** - *true* - *false* Default value: *false* **System Role:** Target, Proxy	SAP Analytics Cloud

Name	Description	System Type
`sac.include.if.match.wildcard.header`	This property makes the SAP Analytics Cloud connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. The header could be used by an SAP Analytics Cloud system for entity versioning. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Analytics Cloud
`sac.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP Analytics Cloud target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. Default value: *displayName* If the property is not specified, the search is done by the default attribute: `displayName`. **System Role:** Target	SAP Analytics Cloud

Name	Description	System Type
`sac.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Analytics Cloud. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* Default value: *userName* **System Role:** Target	SAP Analytics Cloud

Name	Description	System Type
`sac.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP Analytics Cloud
`sac.user.filter`	When specified, only those SAP Analytics Cloud users matching the filter expression will be read. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** For example: *userName eq "SmithJ"* **System Role:** Source	SAP Analytics Cloud
`sac.group.filter`	When specified, only those SAP Analytics Cloud groups matching the filter expression will be read. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Analytics Cloud

Name	Description	System Type
`sac.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with PATCH requests, and below which they are provisioned with PUT request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *200000* For example: • PATCH requests: If you have a group with 700 members and you update the group by adding another 1 200 members, setting this property to 900 results in the following: As 1900 (the target count of the members) is above the threshold number of 900, 2 PATCH requests will be sent to the SAP Analytics Cloud target system. The first request will add 900 group members and the second request will add 300 group members. The threshold number you set defines the maximum number of group members processed per batch. • PUT request: If you have a group with 700 members and you update the group by adding another 100 members, setting this property to 900 results in the following: As 800 (the target count of the members) is below the threshold number of 900, 1 PUT request with 800 group members will be sent to the SAP Analytics Cloud target system to update the group.	SAP Analytics Cloud

Name	Description	System Type
	Note If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. **Note** Regardless of the threshold number you define, when removing group members in SAP Analytics Cloud, the maximum number of members which can be removed per one **PATCH** request is 98. **System Role:** Target	
`sac.patch.group.members.of.nested.groups`	If you set this property to *true*, Identity Provisioning will update only user members of a group in SAP Analytics Cloud target system. The update will be executed on batches via PATCH requests. This will preserve the group hierarchy with nested groups in the SAP Analytics Cloud backend. **Note** You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Analytics Cloud
`ep.user.filter`	When specified, only those SAP Enterprise Portal users matching the filter expression will be read. For more information, see Filtering.	SAP Enterprise Portal
`ep.group.filter`	When specified, only those SAP Enterprise Portal groups matching the filter expression will be read. For more information, see Filtering.	SAP Enterprise Portal

Name	Description	System Type
`bn.user.filter`	When specified, only those SAP Business Network users matching the filter expression will be read. **Possible values:** • *userName eq "Julie Armstrong"* • *userName sw "J"* • *name.familyName eq "Armstrong"* • *emails eq "julie.armstrong@example.com"* **System Role:** Source	SAP Business Network
`bn.group.filter`	When specified, only those SAP Business Network groups matching the filter expression will be read. **Possible values:** *displayName eq "Employees"* **System Role:** Source, Proxy	SAP Business Network
`bn.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. Default value: *userName* If the service finds an existing user by userName, it updates this user with the data of the conflicting one. If the service does not find an existing user by userName, the creation of the conflicting user fails. **System Role**: Target	SAP Business Network
`bn.include.if.match.wildcard.header`	Makes the connector send the `If-Match` HTTP header with a value of "*" for every request to the target system. This header could be used by a SCIM system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Business Network

Name	Description	System Type
`bn.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set `"scope": "createEntity"`. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Note** Updating a group by removing all its members doesn't work. When executing a remove operation, groups must have at least one member. Users and groups can be updated in the target system in various cases, such as: • In the source system, some user or group attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users or groups not to be read anymore. • A user or a group is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity scope` in the transformation of your target or	SAP Business Network

Name	Description	System Type
	proxy system. See:Transformation Expressions [page 391] → *deleteEntity*. **Possible values:** • *true* • *false* Default value for proxy systems: *true* Default value for target systems: *false* **System Role**: Target, Proxy	
`bn.content.type`	This property makes SAP Business Network connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Business Network could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Business Network
`bn.api.key`	An API Key represents the unique key that identifies a particular application as a legitimate consumer of an API. **System Role:**Source, Target, Proxy	SAP Business Network
`bn.realm.id`	The realm name is part of the URL you use to access SAP Business Network. **System Role:**Source, Target, Proxy	SAP Business Network

Name	Description	System Type
`abap.host.timezone`	Specifies the time zone of SAP Application Server ABAP on-premise systems. The value is used for calculating the correct assignments validity in case your SAP AS ABAP and Identity Provisioning tenant are running in different time zones. **Possible values:** The value should be provided in the following format: **`UTC+/- offset`**. For example: **`UTC+02:00`**, **`UTC-04:00`**, **`UTC+03:30`**. Internet Assigned Numbers Authority (IANA) Time Zone database format is also supported. For more information, see RFC 6557: Procedures for Maintaining the Time Zone Database . **System Role:** Source	SAP Application Server ABAP

Name	Description	System Type
`pdw.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in Procurement Data Warehouse. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Default value: **userName** Possible values: • **emails[0].value** • **userName,emails[0].value** **Note** If this property is missing, or you've deleted it, and the service does not find such a *userName*, it will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is unsuccessful too, the creation of the conflicting user fails. **System Role:** Target	Procurement Data Warehouse

Name	Description	System Type
`pdw.group.prefix`	This property distinguishes procurement data warehouse groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`PDW_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the procurement data warehouse source system and will be provisioned to the target system with the following name pattern: **`PDW_<GroupDisplayName>`**. This way procurement data warehouse groups in the target system will be distinguished from groups provisioned from other applications. • When **set in the target system**, only groups containing the **`PDW_`** prefix in their display name will be provisioned to procurement data warehouse. Groups without this prefix in the display name won't be provisioned. If the property is not set, the procurement data warehouse groups will be read and provisioned to the target system with their actual display names. **System Role:** Source, Target	Procurement Data Warehouse
`pdw.support.bulk.operation`	Set this property to *true* if you want to enable SCIM bulk operations for provisioning users. That means, the Identity Provisioning service can write, update, and delete a potentially large collection of users in a single request. For more information, see: SCIM Protocol: Bulk Operations If not specified, the default value is *false*. **Note** SCIM bulk operations are not supported for provisioning groups to procurement data warehouse. **System Role:** Target	Procurement Data Warehouse

Name	Description	System Type
`pdw.bulk.operations.max.count`	If you have enabled the SCIM bulk operations, you can use this property to set the number of users to be provisioned per request. Default value: **`20`** **Note** The value must not exceed the number of entities defined by the procurement data warehouse system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Request Entity Too Large*). **System Role:** Target	Procurement Data Warehouse
`pdw.user.filter`	When specified, only those procurement data warehouse users matching the filter expression will be read. For example: - *userName eq "Julie Armstrong"* - *userName sw "J"* - *emails eq "julie.armstrong@example.com"* **System Role:** Source	Procurement Data Warehouse
`pdw.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because a SCIM system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	Procurement Data Warehouse

Name	Description	System Type
`s4hana.afc.group.filter`	When specified, only those SAP Advanced Financial Closing groups matching the filter expression will be read. Supported operators: **eq** (equal), **sw** (starts with) and **co** (contains) **Possible values:** For example: *displayName eq "Administrators"* **System Role:** Source, Proxy	SAP Advanced Financial Closing
`s4hana.afc.user.filter`	When specified, only those SAP Advanced Financial Closing users matching the filter expression will be read. Supported operators: **eq** (equal), **sw** (starts with) and **co** (contains) **Possible values:** For example: • *userName eq "Julie Armstrong"* • *emails eq "julie.armstrong@example.com"* • *name.familyName sw "A"* • *name.givenName co "Ju"* **System Role:** Source, Proxy	SAP Advanced Financial Closing
`s4hana.afc.content.type`	This property makes a SAP Advanced Financial Closing connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Advanced Financial Closing could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Advanced Financial Closing

Name	Description	System Type
`s4hana.afc.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Advanced Financial Closing target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value: *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Advanced Financial Closing
`s4hana.afc.include.if.match.wildcard.header`	Makes the SAP Advanced Financial Closing connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Advanced Financial Closing system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Advanced Financial Closing

Name	Description	System Type
`s4hana.afc.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Advanced Financial Closing

Name	Description	System Type
`s4hana.afc.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Advanced Financial Closing target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *userName* • *emails[0].value* • *userName,emails[0].value* Default value: *userName* **System Role:** Target	SAP Advanced Financial Closing

Name	Description	System Type
`s4hana.afc.group.prefix`	This property distinguishes SAP Advanced Financial Closing groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`AFC_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Advanced Financial Closing source system and will be provisioned to the target system with the following name pattern: **`AFC_<GroupDisplayName>`**. This way SAP Advanced Financial Closing groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Advanced Financial Closing groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`AFC_`** prefix in their display name will be provisioned to SAP Advanced Financial Closing. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Advanced Financial Closing. **System Role:** Source and Target	SAP Advanced Financial Closing

Name	Description	System Type
`s4hana.pp.group.prefix`	**Note** SAP S/4HANA for procurement planning does not support groups. Therefore, configuring the `s4hana.pp.group.prefix` property is irrelevant. This property distinguishes the groups of a given provisioning system by specific prefix that you provide. It is optional and does not appear by default at system creation. • When **set in the source system**, the prefix is prepended to the name of the groups and they are provisioned to the target system with the following name pattern: **`<YOUR_PREFIX>_<GroupDisplayName>`**. This way those groups are distinguished from groups provisioned from other applications. If the property is not set, the groups are read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing **`YOUR_PREFIX_`** prefix in their display name are provisioned there. Groups without this prefix in the display name are not provisioned. If the property is not set, all groups are provisioned to the target system. **System Role:** Source and Target	SAP S/4HANA for procurement planning

Name	Description	System Type
`s4hana.cloud.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP S/4HANA Cloud Public Edition target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. **Note** You can configure this property only when the integration between a human resource (HR) system and SAP S/4HANA Cloud Public Edition target system is **OFF**. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP S/4HANA Cloud Public Edition

Name	Description	System Type
`s4hana.onprem.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP S/4HANA On-Premise target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID*, it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP S/4HANA On-Premise

Name	Description	System Type
`ibp.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Integrated Business Planning target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP Integrated Business Planning

Name	Description	System Type
`maco.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Market Communication for Utilities target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP Market Communication for Utilities

Name	Description	System Type
`marketing.cloud.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Marketing Cloud target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP Marketing Cloud

Name	Description	System Type
`a4c.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP BTP ABAP environment target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID* **System Role:** Target	SAP BTP ABAP environment

Name	Description	System Type
`c4c.group.prefix`	This property distinguishes SAP Sales Cloud and SAP Service Cloud groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`C4C_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Sales Cloud and SAP Service Cloud source system and will be provisioned to the target system with the following name pattern: **`C4C_<GroupDisplayName>`**. This way SAP Sales Cloud and SAP Service Cloud groups in the target system will be distinguished from groups provisioned from other applications. • When **set in the target system**, only groups containing the **`C4C_`** prefix in their display name will be provisioned to SAP Sales Cloud and SAP Service Cloud. Groups without this prefix in the display name won't be provisioned. If the property is not set, the SAP Sales Cloud and SAP Service Cloud groups will be read and provisioned to the target system with their actual display names. **System Role:** Source, Target	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`s4hana.cloud.roles.prefix`	This property distinguishes SAP S/4HANA Cloud Public Edition roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`S4HANA_CLOUD_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP S/4HANA Cloud Public Edition source system and will be provisioned to the target system with the following name pattern: **`S4HANA_CLOUD_<role_name>`** . This way SAP S/4HANA Cloud Public Edition roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP S/4HANA Cloud Public Edition roles will be read and provisioned to the target system with their actual role names. • When **set in the target system**, only roles containing the **`S4HANA_CLOUD_`** prefix in their role name will be provisioned to SAP S/4HANA Cloud Public Edition. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be provisioned to SAP S/4HANA Cloud Public Edition. **System Role:** Source and Target	SAP S/4HANA Cloud Public Edition

Name	Description	System Type
`ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see Thresholds Prevent Unintended Deletion of Users when Provisioning with SAP Cloud Identity Services. The property is optional and is defined on the target systems only. It is not added at system creation. The expected value is a positive integer without any separators, such as a space, comma, or period. Controlling the deletion works as follows: 1. You add the `ips.delete.threshold.users` property on the target system before running a job and define a threshold value, for example: *500*. 2. You run a read or resync job that is expected to delete a huge number of users. As a result, expect the following behavior: • If the number of the users to be deleted is lower or equal (for example: *400* or *500*) to the defined threshold value of *500*, Identity Provisioning continues with the deletion. • If the number of the users to be deleted is greater (for example: *1000*) than the defined threshold value of *500*, Identity Provisioning does not delete any users. Instead, the service marks the expected to be deleted users as failed in the job statistics. An error message in the job logs explains that users cannot be deleted as the defined threshold is exceeded. **System Role:** Target	All systems

Name	Description	System Type
`ips.delete.threshold.groups`	Use this property to control the number of groups or group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups or group assignments, for example by adding a filter or condition. For more information, see Thresholds Prevent Unintended Deletion of Users when Provisioning with SAP Cloud Identity Services. The property is optional and is defined on the target systems only. It is not added at system creation. The expected value is a positive integer without any separators, such as a space, comma, or period. Controlling the deletion works as follows: 1. You add the `ips.delete.threshold.groups` property on the target system before running a job and define a threshold value, for example: *500*. 2. You run a read or resync job that is expected to delete a huge number of groups. As a result, expect the following behavior: • If the number of the groups to be deleted is lower or equal (for example: *400* or *500*) to the defined threshold value of *500*, Identity Provisioning continues with the deletion. • If the number of the groups to be deleted is greater (for example: *1000*) than the defined threshold value of *500*, Identity Provisioning does not delete any groups. Instead, the service marks the expected to be deleted groups as failed in the job statistics. An error message in the job logs explains that groups cannot be deleted as the defined threshold is exceeded. **System Role:** Target	• Identity Authentication • Local Identity Directory • SAP Advanced Financial Closing • SAP Advanced Workflow • SAP Analytics Cloud • SAP Ariba Applications • SAP BTP Account Members (Neo) • SAP BTP Java/HTML5 apps (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Business Network • SAP Central Business Configuration • SAP Commerce Cloud • SAP Concur • SAP CPQ • SAP Data Custodian • SAP Document Center • SAP Fieldglass • SAP Field Service Management • SAP HANA Database • SAP Jam Collaboration • SAP S/4HANA for procurement planning • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors • SAP SuccessFactors Learning • Sales Cloud – Analytics & AI • Cloud Foundry UAA Server • Google G Suite • LDAP Server • Microsoft Active Directory • Microsoft Entra ID • SCIM System • SSH Server (Beta)

Name	Description	System Type
`ips.delete.threshold.roles`	Use this property to control the number of roles or user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of roles or user assignments of a role, for example by adding a filter or condition. For more information, see Thresholds Prevent Unintended Deletion of Users when Provisioning with SAP Cloud Identity Services. The property is optional and is defined on the target systems only. It is not added at system creation. The expected value is a positive integer without any separators, such as a space, comma, or period. Controlling the deletion works as follows: 1. You add the `ips.delete.threshold.roles` property on the target system before running a job and define a threshold value, for example: *500*. 2. You run a read or resync job that is expected to delete a huge number of roles. As a result, expect the following behavior: • If the number of the roles to be deleted is lower or equal (for example: *400* or *500*) to the defined threshold value of *500*, Identity Provisioning continues with the deletion. • If the number of the roles to be deleted is greater (for example: *1000*) than the defined threshold value of *500*, Identity Provisioning does not delete any roles. Instead, the service marks the expected to be deleted roles as failed in the job statistics. An error message in the job logs explains that roles cannot be deleted as the defined threshold is exceeded. **System Role:** Target	SAP BTP ABAP environment SAP Application Server ABAP SAP Integrated Business Planning SAP Market Communication for Utilities SAP Marketing Cloud SAP S/4HANA Cloud Public Edition SAP S/4HANA On-Premise

Name	Description	System Type
`ioa.content.type`	This property makes an intelligent opportunity analyzer connector to send a specified value for the *Content-Type* HTTP header. This is needed because intelligent opportunity analyzer could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	Intelligent Opportunity Analyzer
`ioa.include.if.match.wildcard.header`	Makes the intelligent opportunity analyzer connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an intelligent opportunity analyzer system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	Intelligent Opportunity Analyzer
`ioa.user.filter`	When specified, only those intelligent opportunity analyzer users matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"* • **System Role:** Source, Proxy	Intelligent Opportunity Analyzer

Name	Description	System Type
`ioa.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in intelligent opportynity analyzer. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attributes. This property defines by which unique attributes the existing user to be searched and resolved. Intelligent opportynity analyzer supports two user unique attributes for managing conflict resolution: *username* and *email*. Both of the attributes are mandatory. The email is a multivalue attribute, indicating that a user may have multiple unique emails. According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[*].value*. If the service finds an existing user with such emails (at least one identical email is needed), it updates this user with the data of the conflicting one. If a user with such emails is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, emails[*].value*. If the service finds an existing user with both userName and email, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Note** The uniqueness of a user in the target system is determined not only by the individual attributes or the combination of both, but also by considering whether one or multiple existing users in the target system share the same values for these unique attributes. For more information, see **User Update and Unique-**	Intelligent Opportunity Analyzer

Name	Description	System Type
	ness in SAP Ariba Category Management [page 1012]. **Possible values:** • *userName* • *emails[*].value* • *userName, emails[*].value* Default value: *userName* **System Role:** Target	
`awf.domain`	The domain name is the name of your SAP Advanced Workflow tenant. If you don't know your tenant name, contact your supervisor or administrator, or refer to the email notification you received when your account was created. **System Role:** Source, Target, Proxy	SAP Advanced Workflow
`awf.user.filter`	When specified, only those SAP Advanced Workflow users matching the filter expression will be read. **Possible values:** • *userName eq "Julie Armstrong"* • *userName sw "J"* • *name.familyName eq "Armstrong"* • *emails eq "julie.armstrong@example.com"* • *userName eq "Julie Armstrong" and emails.value eq "julie.armstrong@example.com"* **System Role:** Source	SAP Advanced Workflow

Name	Description	System Type
`awf.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Advanced Workflow system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Advanced Workflow

Name	Description	System Type
`awf.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Advanced Workflow

Name	Description	System Type
`awf.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Advanced Workflow. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **Default behavior**: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. Default value: *userName* **System Role:** Target	SAP Advanced Workflow
`cim.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** For example: *name.familyName eq "SmithJ"* **System Role:** Source, Proxy	SAP Ariba Central Invoice Management
`cim.group.filter`	When specified, only those groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Ariba Central Invoice Management. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[*].value*. If the service finds an existing user with at least one of the emails of the user in the source system, it updates this existing user with the data of the conflicting one. If a user with such an email is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[*].value*. If the service finds an existing user by *userName* and at least one of the emails of the user in the source system, it updates this user with the data of the conflicting one. If a user with such *userName* and *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • **Possible values:** • *userName* • *emails[*].value* • *userName,emails[*].value* Default value: *userName* **System Role:** Target	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Central Invoice Management target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.include.if.match.wildcard.header`	Makes the SAP Central Invoice Management connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Central Invoice Management system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Ariba Central Invoice Management
`cim.content.type`	This property makes a SAP Central Invoice Management connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Central Invoice Management could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.group.prefix`	This property distinguishes SAP Central Invoice Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CIM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Central Invoice Management source system and will be provisioned to the target system with the following name pattern: **`CIM_<GroupDisplayName>`**. This way SAP Central Invoice Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Central Invoice Management groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`CIM_`** prefix in their display name will be provisioned to SAP Central Invoice Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Central Invoice Management. **System Role:** Source and Target	SAP Ariba Central Invoice Management
`cim.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, Identity Provisioning will replace it with the default value (20). **System Role:** Target	SAP Ariba Central Invoice Management

Name	Description	System Type
`cim.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: User Management (SCIM) for SAP Ariba Central Invoice Management **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Ariba Central Invoice Management
`ecp.user.filter`	When specified, only those SAP SuccessFactors Employee Central Payroll users matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *userName eq "JohnSmith"* • Value = *userName sw "J"* • Value = *emails.value eq "john.smith@example.com"* **System Role:** Source, Proxy	SAP SuccessFactors Employee Central Payroll
`ecp.group.filter`	When specified, only those groups matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *displayName eq "ProjectTeam1"* • Value = *displayName sw "P"* **System Role:** Source, Proxy	SAP SuccessFactors Employee Central Payroll

Name	Description	System Type
`ecp.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP SuccessFactors Employee Central Payroll. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. Possible values: *userName* **System Role:** Target	SAP SuccessFactors Employee Central Payroll
`ecp.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP SuccessFactors Employee Central Payroll target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP SuccessFactors Employee Central Payroll

Name	Description	System Type
`ecp.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP SuccessFactors Employee Central Payroll

Name	Description	System Type
`ecp.include.if.match.wildcard.header`	Makes the SAP SuccessFactors Employee Central Payroll connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP SuccessFactors Employee Central Payroll system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP SuccessFactors Employee Central Payroll
`ecp.content.type`	This property makes a SAP SuccessFactors Employee Central Payroll connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP SuccessFactors Employee Central Payroll could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP SuccessFactors Employee Central Payroll

Name	Description	System Type
`ecp.group.prefix`	This property distinguishes SAP SuccessFactors Employee Central Payroll groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **ECP_** You can use the example value or provide your own. • When set in the source system, the prefix will be prepended to the name of the groups that are read from the SAP SuccessFactors Employee Central Payroll source system and will be provisioned to the target system with the following name pattern: ECP_GroupDisplayName. This way SAP SuccessFactors Employee Central Payroll groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP SuccessFactors Employee Central Payroll groups will be read and provisioned to the target system with their actual display names. • When set in the target system, only groups containing the ECP_ prefix in their display name will be provisioned to SAP SuccessFactors Employee Central Payroll. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP SuccessFactors Employee Central Payroll. **System Role:** Source and Target	SAP SuccessFactors Employee Central Payroll
`ecp.sap-client`	Use this property to specify the SAP client number (a three-digit number) of your SAP SuccessFactors Employee Central Payroll system. For example: **102**	SAP SuccessFactors Employee Central Payroll

Name	Description	System Type
`cm.user.filter`	When specified, only those SAP Ariba Category Management users matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"* • *emails.value eq "john.doe@example.com" or emails.value eq "john.d@example.com" or emails.value eq "j.doe@example.com"* **System Role:** Source, Proxy	SAP Ariba Category Management

Name	Description	System Type
`cm.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Ariba Category Management. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attributes. This property defines by which unique attributes the existing user to be searched and resolved. SAP Ariba Category Management supports two user unique attributes for managing conflict resolution: *username* and *email*. The username is a mandatory attribute, while the email is an optional, multivalue attribute, indicating that a user may have multiple unique emails. According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[*].value*. If the service finds an existing user with such emails (at least one identical email is needed), it updates this user with the data of the conflicting one. If a user with such emails is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName, emails[*].value*. If the service finds an existing user with both userName and email, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Note** The uniqueness of a user in the target system is determined not only by the individual attributes or the combination of both, but also by considering whether one or multiple existing users in the target system share the same values for these unique attributes. For more information, see **User Update and Unique-**	SAP Ariba Category Management

Name	Description	System Type
	ness in SAP Ariba Category Management [page 1012]. **Possible values:** • *userName* • *emails[*].value* • *userName, emails[*].value* Default value: *userName* **System Role:** Target	

Name	Description	System Type
`cm.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Ariba Category Management

Name	Description	System Type
`cm.include.if.match.wildcard.header`	Makes the SAP Ariba Category Management connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Ariba Category Management system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Ariba Category Management
`cm.content.type`	This property makes a SAP Ariba Category Management connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Ariba Category Management could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Ariba Category Management
`hana.cloud.db.group.filter`	When specified, only those SAP HANA Cloud Database Services groups matching the filter expression will be read. For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP HANA Cloud Database Services
`hana.cloud.db.user.filter`	When specified, only those SAP HANA Cloud Database Services users matching the filter expression will be read. For example: *userName eq "SmithJ"* **System Role:** Source, Proxy	SAP HANA Cloud Database Services

Name	Description	System Type
`hana.cloud.db.content.type`	This property makes a SAP HANA Cloud Database Services connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP HANA Cloud Database Services could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP HANA Cloud Database Services
`hana.cloud.db.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP HANA Cloud Database Services target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP HANA Cloud Database Services

Name	Description	System Type
`hana.cloud.db.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP HANA Cloud Database Services. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *urn:ietf:params:scim:schemas:extension:sap:2.0:U ser:userId*. If the service finds an existing user with such *urn:ietf:params:scim:schemas:extension:sap:2.0:U ser:userId*, it updates this user with the data of the conflicting one. If a user with such attribute value is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,urn:ietf:params:scim:schemas:extension:sap:2.0:User:userId*. If the service finds an existing user with such *userName* or *urn:ietf:params:scim:schemas:extension:sap:2.0:User:userId*, it updates this user with the data of the conflicting one. If a user with such *userName* or *urn:ietf:params:scim:schemas:extension:sap:2.0:User:userId* is not found, the creation of the conflicting user fails. **Possible values:** • *userName* • *urn:ietf:params:scim:schemas:extension:sap:2.0:User:userId* • *userName,urn:ietf:params:scim:schemas:extension:sap:2.0:User:userId* Default value: *userName* **System Role:** Target	SAP HANA Cloud Database Services

Name	Description	System Type
`hana.cloud.db.authenticationType`	Specifies the method by which users authenticate when connecting to the database. **Possible values:** JWT (Users authenticate via JWT tokens issued by an identity provider.) **System Role:** Target, Proxy	SAP HANA Cloud Database Services
`hana.cloud.db.instance.id`	Refers to a unique identifier associated with a specific database instance within the SAP HANA Cloud. **System Role:** Source, Target	SAP HANA Cloud Database Services
`hana.cloud.db.instance.type`	Refers to the type of instance being configured or used within the SAP HANA Cloud. The value can be set to: • **hdb** - SAP HANA Database • **hdlre** - SAP HANA Data Lake Relational Engine Default value: **hdb** **System Role:** Source, Target	SAP HANA Cloud Database Services
`hana.cloud.db.providerName`	Specifies the identity provider (IdP) that is responsible for handling authentication requests. **System Role:** Target	SAP HANA Cloud Database Services

Name	Description	System Type
`hana.cloud.db.group.prefix`	(Optional) This property distinguishes SAP HANA Cloud Database Services groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`HANA_Cloud_DB_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP HANA Cloud Database Services source system and will be provisioned to the target system with the following name pattern: **`HANA_Cloud_DB_<GroupDisplayName>`**. This way SAP HANA Cloud Database Services groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP HANA Cloud Database Services groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`HANA_Cloud_DB_`** prefix in their display name will be provisioned to SAP HANA Cloud Database Services. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP HANA Cloud Database Services. **System Role:** Source, Target	SAP HANA Cloud Database Services
`en.user.filter`	When specified, only those SAP Enable Now users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:**Source, Proxy	SAP Enable Now

Name	Description	System Type
`en.group.filter`	When specified, only those SAP Enable Now groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:** Source, Proxy	SAP Enable Now
`en.content.type`	This property makes a SAP Enable Now connector to send a specified value for the *Content-Type* HTTP header. This is needed because SAP Enable Now could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* Default value: *application/scim+json* **System Role:** Target, Proxy	SAP Enable Now
`en.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. Default value: *userName* If the service finds an existing user by userName, it updates this user with the data of the conflicting one. If the service does not find an existing user by userName, the creation of the conflicting user fails. **System Role**: Target	SAP Enable Now

Name	Description	System Type
`en.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Enable Now target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Enable Now
`en.include.if.match.wildcard.header`	Makes the SAP Enable Now connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Enable Now system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Enable Now

Name	Description	System Type
`en.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target	SAP Enable Now

Name	Description	System Type
`en.group.prefix`	(Optional) This property distinguishes SAP Enable Now groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`EN_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Enable Now source system and will be provisioned to the target system with the following name pattern: **`EN_<GroupDisplayName>`**. This way SAP Enable Now groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Enable Now groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`EN_`** prefix in their display name will be provisioned to SAP Enable Now. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Enable Now. **System Role:** Source, Target	SAP Enable Now
`sig.user.filter`	When specified, only those SAP Signavio Process Transformation Suite users matching the filter expression will be read. **Possible values:** For example: *userName eq "SmithJ"* **System Role:**Source, Proxy	SAP Signavio Process Transformation Suite
`sig.group.filter`	When specified, only those SAP Signavio Process Transformation Suite groups matching the filter expression will be read. **Possible values:** For example: *displayName eq "ProjectTeam1"* **System Role:**Source, Proxy	SAP Signavio Process Transformation Suite

Name	Description	System Type
`sig.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system via this filter, the creation will fail. **Default behavior**: This property is missing during system creation. Its default value is *userName*. This means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. Default value: *userName* **System Role:** Target	SAP Signavio Process Transformation Suite
`sig.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `sig.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Signavio Process Transformation Suite

Name	Description	System Type
`sig.include.if.match.wildcard.header`	Makes the SAP Signavio Process Transformation Suite connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Signavio Process Transformation Suite system for entity versioning. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Signavio Process Transformation Suite
`sig.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Signavio Process Transformation Suite

Name	Description	System Type
`sig.content.type`	Makes the connector send a specified value for the *Content-Type* HTTP header. This is needed because an SAP Signavio Process Transformation Suite system could potentially not implement the protocol in the specification, which states that a system must accept *application/scim+json* as a value of the *Content-Type* header. **Possible values:** For example: *application/json* If the property is not specified, the default value is taken: *application/scim+json* **System Role:** Target, Proxy	SAP Signavio Process Transformation Suite
`sig.tenant.id`	The identifier of your SAP Signavio Process Transformation Suite tenant. **System Role:** Source, Target, Proxy	SAP Signavio Process Transformation Suite
`sig.group.members.paging.enabled`	Enables paging of group members. **Possible values:** • *true* • *false* **Default value:** *true* **System Role:** Source, Proxy	SAP Signavio Process Transformation Suite
`sig.user.groups.paging.enabled`	Enables paging of user's groups. **Possible values:** • *true* • *false* **Default value:** *true* **System Role:** Source, Proxy	SAP Signavio Process Transformation Suite
`sig.group.members.page.size`	The number of group members that SAP Signavio Process Transformation Suite returns per request when reading a group. **Default value:** 1000 **System Role:** Source, Proxy	SAP Signavio Process Transformation Suite

Name	Description	System Type
`s4hana.cloud.group.members.page.size`	The number of group members that SAP S/4HANA Cloud Public Edition returns per request when reading a group. **Default value:** 20000 **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)
`ibp.group.members.page.size`	The number of group members that SAP Integrated Business Planning returns per request when reading a group. **Default value:** 20000 **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)
`ibp.user.groups.page.size`	The number of user groups that SAP Integrated Business Planning returns per request when reading a group. **Default value:** 20000 **System Role:** Source, Proxy	SAP Integrated Business Planning (using version 2 - SCIM Interface for IAM)
`s4hana.cloud.user.groups.page.size`	The number of user groups that SAP S/4HANA Cloud Public Edition returns per request when reading a group. **Default value:** 20000 **System Role:** Source, Proxy	SAP S/4HANA Cloud Public Edition (using version 3 - System for Cross-domain Identity Management (SCIM) API)
`sig.user.groups.page.size`	The number of user groups that SAP Signavio Process Transformation Suite returns per request when reading a user. **Default value:** 1000 **System Role:** Source, Proxy	SAP Signavio Process Transformation Suite

Name	Description	System Type
`sig.group.prefix`	This property distinguishes SAP Signavio Process Transformation Suite groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SIG_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Signavio Process Transformation Suite source system and will be provisioned to the target system with the following name pattern: **`SIG_<GroupDisplayName>`**. This way SAP Signavio Process Transformation Suite groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Signavio Process Transformation Suite groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`SIG_`** prefix in their display name will be provisioned to SAP Signavio Process Transformation Suite. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Signavio Process Transformation Suite. **System Role:** Source, Target	SAP Signavio Process Transformation Suite

Name	Description	System Type
`rgm.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). SAP Revenue Growth Management supports the following unique attributes which are automatically filled in during system creation: **`userName,emails[0].value,externalId`**. If the service finds an existing user by at least one of the unique attributes, it updates this user with the data of the conflicting one. If such a user is not found, the update of the conflicting user fails. If more than one users with these unique attributes are found, the update fails. Default value: *userName,emails[0].value,externalId* System Role: Target	SAP Revenue Growth Management
`rgm.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails[0].value`**, and **`externalId`**, according to the API syntax of SAP Revenue Growth Management. **Possible values:** text/ numeric string For example: • *userName eq "johnbrown" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName sw "J" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* > **Note** > These combinations are valid for both 'or' and 'and' operators. **System Role:** Source, Proxy	SAP Revenue Growth Management

Name	Description	System Type
`rgm.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In this case, the existing group only needs to be updated. This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is **`['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']`**. Currently, it is the only unique attribute that is supported. When set, you can expect the following behavior: • If a group with the given unique attribute is found in the target system, the group that you try to provision will overwrite the existing one. • If a group with the given unique attribute is not found in the target system, the group that you try to provision will not be created in the target system. **Possible values:** If the property is not specified, the search is done by the default attribute: `['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']` **System Role:** Target	SAP Revenue Growth Management
`rgm.group.filter`	When specified, only those SAP Revenue Growth Management groups matching the filter expression will be read. **Possible values:** For example: *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group:name eq "ProjectTeam1" or "Students2018"* **System Role:** Source, Proxy	SAP Revenue Growth Management

Name	Description	System Type
`rgm.group.prefix`	This property distinguishes SAP Revenue Growth Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`RGM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Revenue Growth Management source system and will be provisioned to the target system with the following name pattern: **`RGM_<GroupDisplayName>`**. This way SAP Revenue Growth Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Revenue Growth Management groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`RGM_`** prefix in their display name will be provisioned to SAP Revenue Growth Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Revenue Growth Management. **System Role:** Source and Target	SAP Revenue Growth Management

Name	Description	System Type
`rgm.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false* **System Role:** Target, Proxy	SAP Revenue Growth Management
`rgm.userImport.api.dependency.name`	This property holds the value of the dependency name used in the configuration of the SAP Revenue Growth Management consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. For more information, see Integrating Applications. Possible values: Text/numeric string **System Role:** Source, Target, Proxy	SAP Revenue Growth Management

Name	Description	System Type
`c4c.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Sales Cloud and SAP Service Cloud. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • userName • emails[0].value • userName,emails[0].value Default value: *userName* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud

Name	Description	System Type
`c4c.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Sales Cloud and SAP Service Cloud target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. **Possible values:** Default value (when not specified): *displayName* If the property is not specified, the search is done by the default attribute: *displayName* **System Role:** Target	SAP Sales Cloud and SAP Service Cloud
`ariba.applications.api.dependency.name`	This property holds the value of the dependency name used in the configuration of the SAP Ariba Applications consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. For more information, see Integrating Applications. This property is mandatory when using the next-generation SCIM API provided by SAP Ariba Applications. Possible values: Text/numeric string **System Role:** Source, Target, Proxy	SAP Ariba Applications

Name	Description	System Type
`ad.group.flatten.page.size`	This property controls the page size used during Microsoft Active Directory group member flattening. When flattening is enabled (`ad.group.flatten=true` - meaning all nested group members, including users and subgroups, are retrieved), this property specifies how many users and groups are requested from AD in a single page. **Possible values**: • Minimum value: 100 • Maximum value: 1000 If the value is missing, null, or invalid, it defaults to 1000. Default value: 1000 **System Role:** Source	Microsoft Active Directory

1.3.6 Transformations

Transformations help you transform user and group attributes from the data model of the source system to the data model of the target system.

Identity Provisioning provides a default transformation logic for every supported provisioning system. Source systems apply read transformations, target systems apply write transformations, while proxy systems apply both – read and write proxy transformations.

During a provisioning job, the read transformation of the source system converts the system specific JSON representation of users and groups to one common JSON format (also called internal JSON). This common JSON format is then used as a source for passing the data to the target system, which applies the write transformation.

The following examples illustrates how the last name user attribute is read from the SAP S/4HANA Cloud Public Edition source system, transformed and prepared as the family name user attribute for the Identity Authentication target system using both - graphical and JSON text editor.

Graphical Editor

Source System-Specific JSON	Common JSON

Common JSON	Target System-Specific JSON

JSON Text Editor

Source System-Specific JSON	Common JSON	Target System-Specific JSON
Code Syntax { "sourcePath":"$.personalInformation.lastName", "targetPath":"$.name.familyName" },	Code Syntax { "sourcePath":"$.name.familyName", "targetPath":"$.name.familyName" },	Code Syntax { "sourcePath":"$.name.familyName", "targetPath":"$.name.familyName" },

You can adapt the transformation logic, for example, to read only the entities that should be provisioned to the target system. This filter can speed up the processing of the entities and their provisioning to the target system.

Every time you modify the transformation of a provisioning system and save your changes, a new version is created and displayed in the *Transformation History* screen. It lists all versions - from the initial to the current one, and gives you additional information about the last modification date, the person who modified it and a description.

Identity Provisioning provides graphical and JSON text editor for managing provisioning system transformations.

Transformation Types [page 390]
Learn about the types of JSON transformations needed for the provisioning jobs.

Transformation Expressions [page 391]

Transformation Functions [page 428]

Transformation Variables [page 490]

Transformation Conditions [page 496]
A condition defines a JSON filter expression that can be applied to entity types (such as users, groups, and roles) or within attribute mappings. It can be combined with strings, constants, variables, and functions, or used within functions.

Transformation Examples [page 501]
The following examples explain how transformations work.

Transformation Editors [page 505]
Identity Provisioning provides graphical and JSON text editor for managing provisioning system transformations.

1.3.6.1 Transformation Types

Learn about the types of JSON transformations needed for the provisioning jobs.

Context

Two types of transformations occur before the provisioning of entities:

- **Read Transformation** – from the *source system* to the provisioning framework. It reads the data in the source system and transfers it to an intermediate JSON data in the provisioning framework. The reading of entities from the source system can be complete (full read) or partial (delta read). For more information, see Manage Full and Delta Read [page 2459].
- **Write Transformation** – from the provisioning framework to the *target system*. It prepares the data to be written to the target system.

Both transformations result in JSON data.

Every supported system holds and requires specific JSON data. To convert the source JSON data to an intermediate JSON version (which can be used for transformation to a supported target system), the Identity

Provisioning administrator can use the suggested JSON transformation logic on the *Transformations* tab, and adapt it to the required transformation.

All transformations from the source systems transform their specific JSON data to intermediate data according to the *System for Cross-domain Identity Management* (SCIM 2.0) specification.

> ⓘ Note
>
> *Proxy systems* contain both *Read* and *Write* transformations.

Example

If the source JSON data contains the attribute **name**, the read transformation converts this attribute to *name23* in the intermediate JSON data. Then, the write transformation should use the attribute *name23* (instead of **name**) as *sourcePath* attribute.

1.3.6.2 Transformation Expressions

The transformation logic is based on JSON. The order of the expressions in the file is decisive for how the transformation is executed. The transformation actions are performed in the sequence defined in the transformation logic.

There is a different transformation logic for every entity (users, groups, roles). Below are listed some of the JSON expressions you can use.

Transformation Expression	Usage

applyOnElements	Use this JSON expression when the value referenced by the *sourcePath* is a multivalue structure (a list or an array), and you want to apply a function to its elements instead of to the whole structure.
	
	You can use the *applyOnElements* expression in any function, for any provisioning system.
	
	For example, you can see it in the default write transformation of the *SAP Application Server ABAP* proxy system. In this case, the **decode** function reads all members of a user list and converts this list into a byte array. Then, the **toString** function reads this byte-array and converts it back into a string (a list of usernames).
	
	Example
	
	`// Function toString will be applied to all members read from a user list.`
	`...`
	`{`
	`"sourcePath": "$.members[*].value",`
	`"preserveArrayWithSingleElement": true,`
	`"optional": true,`
	`"targetPath": "$.USERLIST[?(@.USERNAME)]",`
	`"functions": [`
	`{`
	`"function": "decode",`
	`"algorithm": "base32",`
	`"skipPadding": true`
	`},`
	`{`
	`"function": "toString",`
	`"applyOnElements": true`
	`}`
	`]`
	`}`
	`...`
	
	Possible values:
	
	• *true*
	• *false*
	
	Data type: Boolean

Transformation Expression	Usage
applyOnJsonAttribute	This expression is deprecated. You can use the new one – *applyOnAttribute*. **Data type**: String

Transformation Expression	Usage

applyOnAttribute	Use this JSON expression when the structure referenced by the *sourcePath* is a complex one (a map), and you want to apply a function to a single member of this map.
	
	In the example below, all occurrences of "SAP" in the values of attribute COMPOSITE_PRIVILEGE are replaced with "test" in the transformation result.
	
	Example
	Privileges in the source system:
	
	`{ "PRIVILEGES": [ { "COMPOSITE_PRIVILEGE": "SAP_01_COMP" }, { "COMPOSITE_PRIVILEGE": "SAP_02_COMP" } ] }`
	
	Example
	Source system transformation:
	
	`{ "mappings": [ { "sourcePath": "$.PRIVILEGES", "targetPath": "$.groups", "functions": [ { "function": "replaceString", "applyOnElements": true, "target": "SAP", "replacement": "test", "applyOnAttribute": "COMPOSITE_PRIVILEGE" } ] } ] }`

Transformation Expression	Usage
	Example Transformation result: `{ "groups": [ { "COMPOSITE_PRIVILEGE": "test_01_COMP" }, { "COMPOSITE_PRIVILEGE": "test_02_COMP" } ] }` **Data type**: String

Transformation Expression	Usage

assignToAttribute	Use this JSON expression when the structure referenced by *targetPath* is a complex one (a map), and you want to assign the result of this mapping to a specific map entry.
	
	In the example below, all occurrences of "SAP" in the values of attribute COMPOSITE_PRIVILEGE are replaced with "test", and the result is assigned to the value of attribute "ASSIGNMENT".
	
	Example
	Privileges in the source system:
	
	`{ "PRIVILEGES": [ { "COMPOSITE_PRIVILEGE": "SAP_01_COMP" }, { "COMPOSITE_PRIVILEGE": "SAP_02_COMP" } ] }`
	
	Example
	Source system transformation:
	
	`{ "mappings": [ { "sourcePath": "$.PRIVILEGES", "targetPath": "$.groups", "functions": [ { "function": "replaceString", "applyOnElements": true, "target": "SAP", "replacement": "test", "applyOnAttribute": "COMPOSITE_PRIVILEGE", "assignToAttribute": "ASSIGNMENT" } ] } ] }`

Transformation Expression	Usage
	Example Transformation result: `{ "groups": [ { "ASSIGNMENT": "test_01_COMP", "COMPOSITE_PRIVILEGE": "SAP_01_COMP" }, { "ASSIGNMENT": "test_02_COMP", "COMPOSITE_PRIVILEGE": "SAP_02_COMP" } ] }` **Data type**: String

Transformation Expression	Usage

condition	A condition specifies a JSON filter expression. It can be applied on a single mapping entity or on the whole entity type. You can use conditions on strings, constants, variables and functions.
	• Condition with **strings**
	Example
	`{ "mappings": [ … { "condition": "$.memberOf contains 'group1'", "constant": "NewDisplayName", "targetPath": "$.displayName" } ] }`
	• Condition with **constants** – AS ABAP (proxy system)
	Example
	`{ "condition": "($.emails.length() > 0) && ($.name.familyName EMPTY false)", "mappings": [ { "sourcePath": "$", "targetPath": "$" }, … }`
	• Condition with format **variables** – SAP S/4HANA Cloud Public Edition (source system)
	Example
	`{ "user": { "condition": "($.validityPeriod.startDate <= '${currentDate}') && ($.validityPeriod.endDate > '${currentDate}')", "mappings": [ {`

Transformation Expression	Usage

```
                "sourcePath":
"$.personID",

"targetVariable":
"entityIdSourceSystem"
            },
```

- Conditions in **functions** – Microsoft Active Directory (target system)

Example

```
"group": {
...
      {
        "sourcePath":
"$.members[*]",
        "targetVariable":
"membersVariable",

"preserveArrayWithSingleElement"
: true,
        "optional": true,
        "functions": [
          {
            "condition":
"@.type != 'Group'",
            "entityType":
"user",
            "applyOnElements":
true,
            "type":
"resolveEntityIds"
          },
          {
            "condition":
"@.type == 'Group'",
            "entityType":
"group",
            "applyOnElements":
true,
            "type":
"resolveEntityIds"
          },
          {
            "condition":
"(@.type != 'Group') &&
('%ldap.attribute.user.id%' !=
'%ldap.attribute.dn%')",
            "function":
"concatString",
            "applyOnElements":
true,
            "applyOnAttribute":
"value",
            "prefix":
"%ldap.attribute.user.id%=",
            "suffix":
",%ldap.user.path%"
```

Transformation Expression	Usage

```
          },
          {
            "condition":
"(@.type == 'Group') &&
('%ldap.attribute.group.id%' !=
'%ldap.attribute.dn%')",
            "function":
"concatString",
            "applyOnElements":
true,
            "applyOnAttribute":
"value",
            "prefix":
"%ldap.attribute.group.id%=",
            "suffix":
",%ldap.group.path%"
          }
        ]
...
```

- Conditions with **functions**

  ### Example

  ```
  {
    "user": {
      "condition": "($.emails
  EMPTY false) &&
  isValidEmail($.emails[0].value)"
  ,
      "mappings": [
        {
          "sourceVariable":
  "entityIdTargetSystem",
          "targetPath": "$.id"
        },
   .....
  }
  ```

- Conditions and **skipOperations**

  ### Example

  #### Code Syntax

  ```
  "condition":"$.groups empty
  false",
  "skipOperations":[
     "update"
  ],
  ```

  First, the condition is evaluated. Users and groups who do not match the condition are skipped. After the condition is evaluated, the skip operation determines

Transformation Expression	Usage
	whether the remaining users will be skipped or provisioned. **Data type**: String

constant	Set a constant if the target system requires attributes that are not defined in the source system.
	
	You can also use schemas to organize and combine multiple constants.
	
	Example
	
	``
	{
	    "targetPath":
	"$.emails[0].type",
	    "constant": "work"
	},
	``
	
	Data type:
	
	- String
	- Integer
	- Boolean
	- JSONObject
	- StringArray
	- IntegerArray
	- BooleanArray
	- JSONObjectArray

Transformation Expression	Usage

correlationAttribute	Correlation attributes are used in the *"user"* mappings of the *Read Transformations* (in source and proxy systems). They mark attributes that are unique for a user in multiple source systems where this user is read from.
	
	The purpose of `correlationAttribute` is to properly count managed identities (users) during the reading process. This is essential because the calculated value is compared to the customer's licensing quota.
	
	• *Use Case 1* – Same attribute in different systems
	
	Example
	Mapping from the *Microsoft Active Directory* read transformation:
	
	`{ "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "correlationAttribute": true },`
	
	Example
	Mapping from the *SAP S/4HANA On-Premise* read transformation:
	
	`{ "sourcePath": "$.userAssignment.userID", "optional": true, "targetPath": "$.userName", "correlationAttribute": true },`
	
	Example
	Mapping from the *LDAP Server* read transformation:
	
	`{ "sourcePath": "$.%ldap.attribute.user.id%[0]", "targetPath": "$.userName", "correlationAttribute": true`

Transformation Expression	Usage

```
    },
```

Result: If the Identity Provisioning reads a user whose username is one and the same in all the three systems (as listed above), the service will consider and count these "3 users" as one managed identity.

- *Use Case 2* – Different attributes from several systems

Example

Mapping from the *Microsoft Active Directory* read transformation:

```
      {
        "sourcePath":
"$.sAMAccountName[0]",
        "targetPath":
"$.userName",
        "correlationAttribute":
true
      },
```

Example

Mapping from the *SAP Analytics Cloud* read transformation:

```
    {
       "sourcePath": "$.emails",
       "targetPath": "$.emails",

"preserveArrayWithSingleElement"
: true
    },
    {
       "sourcePath": "$.emails[?
(@.primary== true)].value",
       "correlationAttribute":
true
    },
```

Example

Mapping from the *Identity Authentication* read transformation:

```
    {
       "sourcePath":
"$.userName",
       "targetPath":
"$.userName",
       "optional": true,
       "correlationAttribute":
true
```

Transformation Expression	Usage

	<pre> },
	     ...
	    {
	       "sourcePath":
	"$.emails[*].value",
	
	"preserveArrayWithSingleElement"
	: true,
	       "targetPath": "$.emails[?
	(@.value)]"
	    },
	    {
	       "sourcePath": "$.emails[?
	(@.primary== true)].value",
	       "correlationAttribute":
	true
	    },</pre>
	Result: If the Identity Provisioning reads a user with a certain username from one system, then it reads a user with a particular e-mail from another system, and then finds a user with the same username and e-mail in a third system (as listed above), the service will consider and count these "3 users" as one managed identity.
	
	Possible values:
	
	• *true*
	• *false*
	
	Data type: Boolean

Transformation Expression	Usage

defaultValue	This JSON expression returns the default value of an attribute when it is set as optional and there is no specific value provided in the `sourcePath`. The **defaultValue** expression comes in handy in the following cases:
	• When an attribute of a previously provisioned entity is later deleted from the source system. After a new provisioning job, the target system will try to get some value for this missing attribute, and thus it will write its default one.
	• When the system transformation contains a *valueMapping* operation. If the value of the mapped attribute is not found as a key in the `"valueMappings"` definitions, or some of the source paths does not return a value, the JSON transformation will use the default one.
	The default value of an attribute can be a *string*, *integer*, *Boolean*, *array*, or empty (null).
	You can add `"defaultValue"` for any attribute, in the transformation of any provisioning system. For example, you can find it in the default transformation of the **Identity Authentication** target system:
	Example
	`...`
	`{`
	`"sourcePath": "$.userType",`
	`"targetPath": "$.userType",`
	`"defaultValue": "employee",`
	`"optional": true`
	`},`
	`...`
	Data type:
	• String
	• Integer
	• Boolean
	• JSONObject
	• StringArray
	• IntegerArray
	• BooleanArray
	• JSONObjectArray

Transformation Expression	Usage

ignore	Use the *ignore* expression if you would like to exclude certain parts of the transformation from being considered during the provisioning. Similar to *condition*, you can set *ignore* on various levels, including on entire entity types such as users or roles, or specific mapping entities. This is applicable for both source and target systems.
	
	Note
	Note that if an entity type is set to be ignored in the read transformations, you won't get any data in the job log statistics for this entity type.
	
	Example
	`"group": { "ignore": true, "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetVariable": "entityIdSourceSystem" }, { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.displayName" }, ...`
	
	Example
	`"user": { "mappings": [ { "ignore": true, "sourcePath": "$.sAMAccountName[0]", "targetVariable": "entityIdSourceSystem" }, { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName" }, ...`
	
	Possible values:
	• *true*

Transformation Expression	Usage
	• *false* **Data type**: Boolean

Transformation Expression	Usage

preserveArrayWithSingleElement	This JSON expression converts an array into a single element. That means, when the Identity Provisioning service reads an array that contains only one element, then in the target system:
	• If **"preserveArrayWithSingleElement"** is set to *true*, this expression will keep the array with the single element as is.
	Example
	The following mapping keeps the array of group members, resolving their IDs, even if the array contains only one member.
	`{ "sourcePath": "$.members[*].value", "preserveArrayWithSingleElement": true, "optional": true, "targetPath": "$.members[?(@.value)]", "functions": [ { "type": "resolveEntityIds" } ] } ...`
	• If **"preserveArrayWithSingleElement"** is set to *false*, this expression will convert the array into the relevant single element.
	Example
	The following mapping converts the array into a single element (a group member), and resolves its ID.
	`{ "sourcePath": "$.members[*].value", "preserveArrayWithSingleElement": false, "optional": true, "targetPath": "$.members[?(@.value)]", "functions": [ { "type": "resolveEntityIds"`

Transformation Expression	Usage
	 **Possible values:** • *true* • *false* **Data type**: Boolean

Transformation Expression	Usage
scope	You can set a scope for an entity attribute, based on its lifecycle. A scope can have the following values: • *createEntity* – An entity attribute is processed only during creation. Transformation mappings without scope are always processed during the creation. **Note** The `createEntity` scope currently applies only to **write** and **proxy write** transformations. **Example** The following mapping provides an initial password during the creation of a user. `{ "user": { "mappings": [ { "scope": "createEntity", "targetPath": "$.Password", "constant": "Initial1" } ] }, ...` • *patchEntity* – When using the *ipsproxy* application and a system that supports SCIM PATCH operation, you may need to perform certain transformations over the PATCH request. To do this, use the `patchEntity` scope in the system transformation. Only mappings with this scope will be processed. **Note** • The Identity Provisioning service supports PATCH requests only for groups, group members (assignments), and users. • The `patchEntity` scope is only applicable for write transformations in **proxy systems**.

Transformation Expression	Usage

	Example
	The following mapping decodes the group ID and preserves the patch request body (payload) into the target system.
	`{ "scope": "patchEntity", "sourceVariable": "entityIdTargetSystem", "targetVariable": "entityIdTargetSystem", "functions": [ { "type": "decode", "algorithm": "base32", "skipPadding": true }, { "function": "toString" } ] }, { "scope": "patchEntity", "sourcePath": "$", "targetPath": "$" },`
	• *deleteEntity* – If an entity has been deleted from the source system or has been set a condition for it not to be read anymore, this entity can "stay" in the target system for the following reasons:
	  • The target system does not support deletion of entities.
	  • You do not want to delete it but only temporary disable/deactivate it.
	  • You want to neither delete it, nor deactivate it but only remove its permissions, or exclude it from some corporate groups.
	If you have to fulfill some of these scenarios for an entity, use the `deleteEntity` scope. It prevents from deleting the entity from the target or proxy system as only updating its status instead. Also, bear in mind the following:
	  • For the affected entity, all transformation mappings that do not contain this scope will be ignored.
	  • If a condition exists on entity type level, it will be ignored as well.
	  • If the `deleteEntity` scope is included in a proxy write transformation, it is taken into account only

Transformation Expression	Usage
	when used in the transformation mapping for the **entityIdTargetSystem** variable. Use this scope for the following systems: • Cloud Foundry UAA server • Identity Authentication • Local Identity Directory • Microsoft Entra ID • Sales Cloud – Analytics & AI • SAP Advanced Financial Closing • SAP Analytics Cloud • SAP Ariba Applications • SAP BTP Account Members (Neo) • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Business Network • SAP Build Work Zone, advanced edition • SAP Build Work Zone, standard edition • SAP Central Business Configuration • SAP Commerce Cloud • SAP SuccessFactors Incentive Management • SAP Concur version 2 • SAP CPQ • SAP Data Custodian • SAP Enterprise Portal • SAP Fieldglass • SAP Field Service Management • SAP Intelligent Agriculture • SAP Jam Collaboration • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors Learning • SAP SuccessFactors version 2 • SAP S/4HANA for procurement planning • SCIM System **Example** **Concur**: The following mapping disables the user account: `{ "user": { "mappings": [ { "scope": "deleteEntity", "constant": "US",`

Transformation Expression	Usage

```
          "targetPath":
"$.Custom21"
        },
        {
          "scope":
"deleteEntity",
          "constant": "",
          "targetPath":
"$.Password"
        },
        {
          "scope":
"deleteEntity",
          "constant": "DEFAULT",
          "targetPath":
"$.LedgerCode"
       },
       {
          "constant": "N",
          "targetPath":
"$.Active",
          "scope": "deleteEntity"
       },
...
```

Example

Microsoft Entra ID: The following mapping disables the user account:

```
{
   "user": {
    "mappings": [

      {
          "constant": false
          "targetPath":
"$.accountEnabled",
          "scope":
"deleteEntity",
        },
...
```

Example

Identity Authentication (SCIM API version 1): The following mapping disables the user account and unassigns the user from all the groups it was a member of:

```
{
   "user": {
    "mappings": [
      {
        "sourceVariable":
"entityIdTargetSystem",
```

Transformation Expression	Usage

```
        "targetPath": "$.id",
        "scope": "deleteEntity"
      },
      {
         "constant": false,
         "targetPath":
"$.active",
         "scope": "deleteEntity"
       },
       {
         "constant": [],
         "targetPath":
"$.corporateGroups",
         "scope": "deleteEntity"
       },
       {
         "constant": [],
         "targetPath":
"$.groups",
         "scope": "deleteEntity"
       },
...
```

Example

Identity Authentication (SCIM API version 2): The following mapping disables the user account.

Disabling a user account is done with a PATCH operation which replaces the value of the `active` user attribute **`true`** with **`false`**. For this, you also need to set `ias.user.update.instead.delete=true` in the Identity Authentication target system.

For more information, see: List of Properties [page 80]

```
{
   "user":{
      "mappings":[
         {

"constant":"urn:ietf:params:scim
:api:messages:2.0:PatchOp",

"targetPath":"$.schemas[0]",

"scope":"deleteEntity"
         },
         {

"constant":"replace",

"targetPath":"$.Operations[0].op
",
```

Transformation Expression	Usage

```
"scope":"deleteEntity"
        },
        {
           "constant":"active",

"targetPath":"$.Operations[0].pa
th",

"scope":"deleteEntity"
        },
        {
           "constant":false,

"targetPath":"$.Operations[0].va
lue",

"scope":"deleteEntity"
        },
...
```

Example

SAP Jam: The following mapping disables the user account in the target system:

```
 "user": {
       "mappings": [

           {

"sourceVariable":
"entityIdTargetSystem",
                "targetPath":
"$.id",
                "scope":
"deleteEntity"
           },
           {
                "constant":
false,
                "targetPath":
"$.active",
                "scope":
"deleteEntity"
           },
...
```

Possible values:

- *createEntity*
- *patchEntity*
- *deleteEntity*

Data type: String

Transformation Expression	Usage

skipOperations	If you want the provisioning job to not execute operations of a certain type on groups and users , use the `skipOperations` expression. You can apply it when you need to avoid creating, deleting, or updating entities.
	
	You can use `skipOperations` only in target system transformations.
	
	• In the following example, the transformation does not allow updating groups in the target system. This approach is valuable when you have done group changes in the target system, and after a new *Read* or *Resync* job, you want these changes to be kept instead of being overwritten by the groups in the source system.
	
	Example
	
	`"group": { "skipOperations": [ "update" ], "mappings": [ {`
	
	• In the following example, the transformation does not allow creating and deleting users in the target system:
	
	Example
	
	`{ "user": { "skipOperations": [ "create", "delete" ], "mappings": [ {`
	
	You can set the transformation to skip the "`create`" operation if you're sure that all entities from the source system already exist in the target – independently from the Identity Provisioning service. That means, they have been created in the target system manually or via a script. Thus, by skipping the "`create`" operation, the identity provisioning job will only provision the changes instead of creating the users all over again in the target. The Identity Provisioning service will skip creating the existing entities and will try to update them. There are two options for resolving the existing users by the service.
	Option 1: If the update operation is performed using a PATCH request, or a PUT request when the system

Transformation Expression	Usage

	is SCIM-based, the Identity Provisioning service will search and resolve existing users based on the system's default or predefined unique attributes.
	For more information about the SCIM-based systems, see System Types [page 70].
	For more information about the unique attributes of your system, see List of Properties [page 80].
	Option 2: In all other cases that differ from the above mentioned (the target system is LDAP-based, RFC-based, SOAP or OData-based), the existing users are resolved by retrieving their IDs. In order for the *skip create* operation to be executed without an error, you need to make a few adjustments in your source and target transformations. This way, the service will search and retrieve the IDs of the entities correctly. An example how to modify your source and target transformations is included below.
	In the following detailed example, *SAP SuccessFactors* is a source system and *SAP S/4HANA Cloud Public Edition*, which is SOAP-based system, is a target. You want all users that exist on both systems to be skipped during creation and to only be updated on the target. If there are users existing only in the source system, they will not be created in the target. To do that:
	1. Open your *SAP SuccessFactors* admin console. For every user that you want to be provisioned and updated in *SAP S/4HANA Cloud Public Edition*, you need to set up one of its predefined custom attributes (*custom01* – *custom15*), entering the *SAP S/4HANA Cloud Public Edition* unique identifier for that user (which is the value of the `personID` attribute). For example, you can do that in the **custom10** attribute.
	2. Then go to the administration console for SAP Cloud Identity Services, and in the *Properties* tab update the `sf.user.attributes` property, adding **custom10** to the list of attributes.
	3. In the *SAP SuccessFactors* source system, add the following extra user mapping. It maps **custom10** to a custom attribute in *SAP S/4HANA Cloud Public Edition*, for example **custom_user_ID**:
	✤ Example
	`{`
	`"user": {`

Transformation Expression	Usage

```
        "mappings": [
           {
            "sourcePath":
"$.custom10",
            "targetPath":
"$.custom_user_ID",
            "optional": true
           },
...
```

4. In the *SAP S/4 HANA Cloud* target system, replace the following user mapping:

Example

```
{
    "user": {
        "mappings": [
          {
             "targetPath":
"$.personID",

"sourceVariable":
"entityIdTargetSystem"
           },
...
```

with:

Example

```
    {
        "sourcePath":
"$.custom_user_ID",
        "targetVariable":
"entityIdTargetSystem"
      },
      {
        "targetPath":
"$.personID",
        "sourcePath":
"$.custom_user_ID"
      },
```

5. (Optional) If there are users that exist only in the source system and you want them to be reported as skipped directly, without being processed further by the Identity Provisioning, adjust the *SAP S/4 HANA Cloud* target transformation by adding the following condition:

Example

Transformation Expression	Usage

	<pre>{
	"user": {
	"condition":
	"$.custom_user_ID EMPTY
	false",
	"mappings": [
	. . .</pre>
	6. Run the first *Read* provisioning job.
	7. Check in the administration console for SAP Cloud Identity Services if the relevant "marked" users are updated, and that the rest are not. Also, check that users that exist only in *SAP SuccessFactors* (if any) are not created in *SAP S/4 HANA Cloud*.
	Such transformations adjustmants are not needed if your target system is SAP Application Server ABAP. In that case the Identity Provisioning service will search and resolve the existing users in the target system by `userName`.
	Note
	If an entity does not exist in the target system (which means, a retrieved ID does not match any target entity), it will neither be created, nor updated.
	Possible values:
	• *create*
	• *update*
	• *delete*
	Data type: String

sourcePath	The *sourcePath* expression denotes the path to an attribute in the input JSON message (could be the source system JSON data or the intermediate one).
	Example
	<pre>{
	"sourcePath":
	"$.name.familyName",
	"targetPath": "$.name.familyName"
	},</pre>
	Data type: String

Transformation Expression	Usage
targetPath	The *targetPath* expression denotes the path where the attribute should be stored in the output JSON message (could be the intermediate or the target system JSON data). **Example** `{ "targetPath": "$.name.familyName", "sourcePath": "$.sn[0]" },` **Data type**: String

Transformation Expression	Usage

type	The type of action to be performed in the mapping. It could be *set*, *remove*, *rename* and *valueMapping*.
	• The *set* type maps an attribute from the source system to an attribute in the target JSON data. If no type is defined, `"type": "set"` is used by default.
	Example
	`{ "type": "set", "targetPath": "$.groups" }`
	• The *remove* type deletes an attribute during transformation. This attribute is not present in the target JSON data.
	Example
	`{ "type": "remove", "targetPath": "$.groups" }`
	• The *rename* type renames the last element of a complex targetPath.
	In the example below, the last element `.lastName` of the targethPath `$.name.lastName` will be renamed with the provided constant value `familyName`. This will result in the following targetPath: `"$.name.familyName",`.
	Code Syntax
	`{ "targetPath": "$.name.lastName", "constant": "familyName", "type": "rename", "optional": true }`
	• The *valueMapping* type allows multiple entity attributes (read from the source system) to be mapped to a single target attribute.
	For example, you can set a mapping condition for a user attribute **user.timeZoneCode**. After the provisioning job, its value will be mapped to a new attribute –

Transformation Expression	Usage
	timezone. The example below provides a number of world locations and their relevant timezone. **Note** If the value of **user.timeZoneCode** is not found as a key in the `valueMappings` definitions, or some of the source paths does not return a value, the JSON transformation will use the default one. (In the example below, the default value is *Europe/Berlin*.) **Example** JSON code for mapping user timezone: `"user": { ... { "type": "valueMapping", "sourcePaths": ["$.user.timeZoneCode"], "targetPath": "$.timezone", "defaultValue": "Europe/Berlin", "valueMappings": [{ "key": ["WDFT"], "mappedValue": "Europe/Berlin" }, { "key": ["ISRAEL"], "mappedValue": "Asia/Jerusalem" }, { "key": ["RUS03"], "mappedValue": "Europe/Moscow" }, { "key": ["AUSNSW"], "mappedValue": "Australia/Sydney" }, { "key": ["UTC+4"], "mappedValue": "Asia/Dubai" }, { "key": ["BRAZIL"], "mappedValue": "America/Sao_Paulo" }, { "key": ["BRZLEA"], "mappedValue": "America/Sao_Paulo" }, { "key": ["MSTNO"], "mappedValue": "America/Phoenix" }, { "key": ["EST"], "mappedValue": "America/New_York" },`

Transformation Expression	Usage
	 **Possible values:** • *set* • *remove* • *rename* • *valueMapping* **Data type**: String

Transformation Expression	Usage
valueMappings	Provides a list with mapped values. It can only be used when *type* is set to **`valueMapping`**. The list contains the keys, which are read from the source system and mapped to values in a single target attribute. The example below provides the list of world locations and their relevant timezone. **Example** JSON code for mapping user timezone: `"user": { ... { "type": "valueMapping", "sourcePaths": ["$.user.timeZoneCode"], "targetPath": "$.timezone", "defaultValue": "Europe/Berlin", "valueMappings": [{ "key": ["WDFT"], "mappedValue": "Europe/Berlin" }, { "key": ["ISRAEL"], "mappedValue": "Asia/Jerusalem" }, { "key": ["RUS03"], "mappedValue": "Europe/Moscow" }, { "key": ["AUSNSW"], "mappedValue": "Australia/Sydney" }, { "key": ["UTC+4"], "mappedValue": "Asia/Dubai" }, { "key": ["BRAZIL"], "mappedValue": "America/Sao_Paulo" }, { "key": ["BRZLEA"], "mappedValue": "America/Sao_Paulo" }, { "key": ["MSTNO"], "mappedValue": "America/Phoenix" }, { "key": ["EST"], "mappedValue": "America/New_York" }, { "key": ["UTC"], "mappedValue": "Etc/UTC" }, { "key": ["UTC+3"], "mappedValue": "Asia/Riyadh" },`

Transformation Expression	Usage
	 Data type: JSONObjectArray

Transformation Expression	Usage
sourcePaths	Specifies paths to attributes in the input JSON message from the source system. The *sourcePaths* can only be used with the *valueMappings* expression, which requires the type to be set to **`valueMapping`**. The number of values in the key arrays must correspond to the number of sourcePaths. In the following example, the value pairs US and New York, US and Dallas, Germany and Berlin in the key arrays correspond to the two sourcePaths: country and city. The *mappedValue* is the value to be written to the *targetPath* attribute, such as timezone, provided that each key value matches the corresponding attribute value (e.g., **`US`** for **`country`** and **`New York`** for **`city`**). **Code Syntax** `{ "sourcePaths": ["$.country", "$.city"], "defaultValue": "UTC", "targetPath": "$.timezone", "type": "valueMapping", "valueMappings": [{ "key": ["US", "New York"], "mappedValue": "EST" }, { "key": ["US", "Dallas"], "mappedValue": "CST" }, { "key": ["Germany", "Berlin"], "mappedValue": "CET" }] },` **Note** Paths to the country and city attributes are provided as exemplary values. These attribute paths might be system-specific. For example, in SAP AS ABAP, the "$.country" path is "$.ADDRESS.COUNTRY". **Data type**: StringArray

Transformation Expression	Usage
optional	Specifies whether attribute's availability is mandatory or optional for a given system. • If set to *true*, this means that the attribute is optional and even if it is missing, provisioning won't fail. • If set to *false* or not set at all, this means that the attribute is mandatory and if it is missing, provisioning will fail. For example, the default read transformation of SAP SuccessFactors shows that if the first name of a user is missing in the source system, this user will be read and provisioned to a target system. However, if the last name of a user is missing, provisioning will fail as this is a mandatory attribute. **Code Syntax** `{ "sourcePath": "$.firstName", "optional": true, "targetPath": "$.name.givenName" }, { "sourcePath": "$.lastName", "targetPath": "$.name.familyName" },` **Possible values:** • *true* • *false* **Data type**: Boolean
sourceVariable	The *sourceVariable* expression denotes a variable that is valid only within a given provisioning system. It shows where the variable will be read from. For more information, see Transformation Variables [page 490] **Data type**: String
targetVariable	The *targetVariable* expression denotes a variable that is valid only within a given provisioning system. It shows where the variable will be written to. For more information, see Transformation Variables [page 490] **Data type**: String

1.3.6.3 Transformation Functions

A function is a hardcoded piece of transformation logic that receives a value denoted by the input specified by a source path or a source variable. As a result, the value is replicated into the target path or target variable, accordingly.

The Identity Provisioning service uses two types of functions: *conditional* [page 429] and *mapping* [page 434] functions. The conditional functions are functions which can be used only in conditional statements. The mapping functions are used in entity transformations and are included as mappings.

Functions can also be chained – that means, the output of one function is the input for the next one. See an example with such functions in the **encode / decode** section below.

For more information, see the tables below.

Conditional Functions

Function	Parameters	Description

isValidEmail	• JSON path attribute which holds the email value
	Required: Yes
	Type: String
	• Possible values:
	  • `$.emails[0].value`
	  • `$.emails[*].value`
		This function verifies whether an e-mail address is valid by checking if the given String value matches the following regex pattern:
		`"[a-zA-Z0-9!#$%&‘'*+/=?^_`{\|}~-]+(?>\\.[a-zA-Z0-9!#$%&‘'*+/=?^_`{|}~-]+)*@(?>[a-zA-Z0-9][a-zA-Z0-9-]*[a-zA-Z0-9]?\\.)+[a-zA-Z0-9](?>[a-zA-Z0-9-]*[a-zA-Z0-9])?"`
		After the check, the function returns a Boolean result.
		This function can be used only as part of a conditional statement.
		EXAMPLE 1:
		In this example, the source JSON code contains the following e-mail address of a user:
		`{ "userName": "test", "emails": [ { "value": "example@company.com", "primary": true } ] }`
		The condition with function *isValidEmail* is the following:
		`{ "condition": "isValidEmail($.emails[0].value)", "mappings": [ {`

Function	Parameters	Description

		<pre>"sourcePath":
		"$.userName",
		
		"targetPath":
		"$.userName"
		},
		{
		
		"sourcePath":
		"$.emails[*].value",
		
		"preserveArrayWithSi
		ngleElement": true,
		
		"targetPath":
		"$.emails[?
		(@.value)]"
		}
		]
		}</pre>
		EXAMPLE 2:
		
		In cases where users have multiple emails, the following condition will validate each email in the emails array:
		
		<pre>{
		"condition":
		"isValidEmail($.emai
		ls[*].value)",
		"mappings": [
		{
		......</pre>

Function	Parameters	Description
isApplicationSpecificGroup	Not applicable	This function verifies whether a group is associated with a particular application configured in SAP Cloud Identity Services - Identity Authentication. It checks if the property `ips.application.id` is set for the provisioning system and whether its value matches the group attribute `$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`. After the check, the function returns a Boolean result. This function can be used only as part of a conditional statement. The function is part of the default write transformation of some target systems (like SAP Advanced Financial Closing).
isRegularGroup	Not applicable	This function verifies whether a group is regular user group. It checks consecutively the values of the group attributes `supportedOperations` and `applicationId` and returns a Boolean result. If one or both of the attributes are missing, the returned result is `true`. Otherwise, the returned value is `false`. This function can be used only as part of a conditional statement. The function is part of the default write transformation of some target systems (like SAP Advanced Financial Closing).

Function	Parameters	Description

isAttributeWithOptionalPrefix	• `attribute-jsonpath` - JSON path attribute
	Required: Yes
	Type: String
	• `property-key` - specifies a property in the system configuration
	Required: Yes
	Type: String
		This function checks whether an attribute value starts with an optional prefix.
		
		The syntax used by the function is as follows:
		
		`isAttributeWithOptionalPrefix(attribute-jsonpath, property-key)`
		
		For example:
		
		`"condition": "isAttributeWithOptionalPrefix($.displayName, s4hana.afc.group.prefix)"`
		
		After the check, the function returns a Boolean result.
		
		The returned result is `true` when one of the following conditions is fulfilled:
		
		• the attribute `attribute-jsonpath` is missing
		• the property `property-key` is missing
		• the value of the attribute `attribute-jsonpath` starts with the value of the property `property-key`
		
		Otherwise, the returned value is `false`.
		
		The function is part of the default write transformation of some target systems (like SAP Advanced Financial Closing).

Function	Parameters	Description

isAttributeWithMandatoryPrefix	• `attribute-jsonpath` - JSON path attribute
	Required: Yes
	Type: String
	• `property-key` - specifies a property in the system configuration
	Required: Yes
	Type: String
		This function checks whether an attribute value starts with a predefined mandatory prefix.
		
		The syntax used by the function is the following:
		
		`isAttributeWithMandatoryPrefix(attribute-jsonpath, property-key)`
		
		For example:
		
		`"condition": "isAttributeWithMandatoryPrefix($.displayName, s4hana.afc.group.prefix)"`
		
		After the check, the function returns a Boolean result.
		
		The returned result is `true` when all of the following conditions are fulfilled:
		
		• the attribute `attribute-jsonpath` is present
		• the property `property-key` is present
		• the value of the attribute `attribute-jsonpath` starts with the value of the property `property-key`
		
		If one or more of the conditions are not fulfilled the returned value is `false`.
		
		The function is part of the default write transformation of some target systems (like SAP Advanced Financial Closing).

Mapping Functions

Function	Parameters	Description

concatString	• **prefix**
	Required: No
	Type: String
	• **suffix**
	Required: No
	Type: Integer; String; Boolean
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function concatenates a string with a prefix or a suffix.
		
		EXAMPLE 1:
		
		In the following transformation example, function *concatString* will be applied to all source logon names (SAM-account user names) read from *Microsoft AD*, adhering a prefix **ips_** and a suffix **123** in the target system. For example, a *sAMAccountName* name **johnsmith** from the source system will be provisioned as **ips_johnsmith123** in the target system.
		
		Example
		
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "concatString", "prefix": "ips_", "suffix": 123 } ] } ... }`
		
		EXAMPLE 2:

Function	Parameters	Description
		In the following transformation example, function *concatString* will be applied to all source user IDs in a source system, converting them into uniform e-mails in the *Microsoft Entra ID* target system. In this case, the *concatString* function takes the value of the *aad.domain.name* property (which is the name of a verified Microsoft Entra ID domain) and adheres it to the *userId*. For example, a source user ID **johnsmith123** can produce a target principal name **johnsmith123@mail.acme.com**. Example `{ "sourcePath": "$.userId", "targetPath": "$.emails[0].value", "correlationAttribute": true, "functions": [ { "function": "concatString", "suffix": "@%aad.domain.name%" } ] }, ...`

Function	Parameters	Description

convertCountryCode	• **outputFormat**
	Required: Yes
	Possible values:
	  • `fullName`
	  • `alpha2`
	  • `alpha3`
	  • `numeric`
	• **inputAttributes**
	Required: Yes
	Possible values:
	  • Single value or list of address attributes which will be used. The function requires attribute `country`.
	  • `issuingCountry`
	• **outputAttribute**
	Required: Yes
	Possible values: `country`
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function converts the countries into format compliant with *ISO 3166-1*.
		
		`{ "sourcePath": "$.addresses", "preserveArrayWithSingleElement": true, "optional": true, "targetPath": "$.addresses", "functions": [ { "type": "convertCountryCode", "outputFormat": "alpha2", "inputAttributes": ["country"], "outputAttribute": "country" } ] }`
		
		EXAMPLE:
		
		In the following transformation example, function *convertCountryCode* will be applied to all source countries read from the source system, converting them in the wanted ISO format. For example, the `country` name *United States* from the source system will be provisioned in the target system as:
		• *US* if the `outputFormat` is *alpha2*;
		• *USA* if the `outputFormat` is *alpha3*;
		• *840* if the `outputFormat` is *numeric*;
		• *United States* if the `outputFormat` is *fullName*.

Function	Parameters	Description
convertCountryRegion	• **outputFormat** Required: Yes Possible values: • `fullName` • `alpha2` • **inputAttributes** Required: Yes Possible values: • `country` • `region` • **outputAttribute** Required: Yes Possible values: `region` • **condition** Required: No Type: String • **applyOnElements** Required: No Type: Boolean Possible values: • true • false • **applyOnAttribute** Required: No Type: String • **assignToAttribute** Required: No Type: String	This function converts the countries into format compliant with *ISO 3166-2*. `{ "condition": "($.addresses[*].region EMPTY false) && ($.addresses[*].country EMPTY false)", "sourcePath": "$.addresses", "preserveArrayWithSingleElement": true, "optional": true, "targetPath": "$.addresses", "functions": [{ "type": "convertCountryRegion", "outputFormat": "alpha2", "inputAttributes": ["region","country"], "outputAttribute": "region" }] }`  EXAMPLE:  In the following transformation example, function *convertCountryRegion* will be applied to all source regions read from the source system, converting them in the wanted ISO format. For example, the `region` name *US-AL* or only *AL* from the source system will be provisioned to the target system as:  • *US-AL* if the `outputFormat` is *alpha2*;

Function	Parameters	Description
		• *Alabama* if the `outputFormat` is *fullName*.

Function	Parameters	Description

convertLocaleCode	• **outputFormat**
	Required: Yes
	Type: String
	Possible values:
	• `bcp47`
	• `iso639`
		This function converts the locale code from the source format into the format required by the target system.
		
		For example, SAP Concur (connector version 3) expects locale codes in *BCP 47* format (like `en-US`, `de-DE`), while Identity Authentication (connector version 2) uses *ISO 639* language codes (such as `EN`, `DE`).
		
		Code Syntax
		`{`
		`"sourcePath":"$.locale",`
		`"targetPath":"$.locale",`
		`"optional":true,`
		`"functions":[`
		`{`
		`"type":"convertLocaleCode",`
		`"outputFormat":"bcp47"`
		`}`
		`]`
		`},`
		
		When converting from or to *ISO 639*, the function works only with the default language codes used in Identity Authentication. You can view them in the SAP Cloud Identity Services administration console under: *Applications & Resources* > *Master Data* > *Languages*. For more information, see Languages Default Master Data
		
		Languages that do not have a defined mapping, such as EO (Esperanto), IA (Interlingua), IO (In-

Function	Parameters	Description
		terlingue), are mapped to English by default.

Function	Parameters	Description

convertTimezoneCode	• **outputFormat**
	Required: Yes
	Type: String
	Possible values:
	• `iana`
	• `sap`
		This function converts the value of a `timezone` attribute into another format, specified by the JSON modifier `"outputFormat"`.
		
		The `"outputFormat"` modifier has two possible values:
		
		• `iana`, which follows the convention **`{AREA}/{LOCATION}`**
		• `sap`, which uses abbreviations
		
		The function retrieves the value of the `timezone` from the specified source path and searches for it within a predefined list of timezones and their corresponding world locations:
		
		Code Syntax
		
		`WET,Europe/Lisbon`
		`WET,Atlantic/Canary`
		`WET,Atlantic/Faroe`
		`WET,Atlantic/Madeira`
		`WAT,Africa/Lagos`
		`WAT,Africa/Algiers`
		`WAT,Africa/Bangui`
		`WAT,Africa/Brazzaville`
		`WAT,Africa/Douala`
		`WAT,Africa/Kinshasa`
		`WAT,Africa/Libreville`
		`WAT,Africa/Luanda`
		`WAT,Africa/Malabo`
		`WAT,Africa/Ndjamena`
		`WAT,Africa/Niamey`
		`WAT,Africa/Porto-Novo`
		`ART,America/Argentina/Buenos_Aires`
		`ART,America/Argentina/Catamarca`

Function	Parameters	Description
		UTC-4,America/Grenada UTC-4,America/Guadeloupe UTC-4,America/Guyana UTC-4,America/Kralendijk UTC-4,America/La_Paz UTC-4,America/Lower_Princes UTC-4,America/Marigot UTC-4,America/Martinique UTC-4,America/Montserrat UTC-4,America/Port_of_Spain UTC-4,America/Puerto_Rico UTC-4,America/Santo_Domingo UTC-4,America/St_Barthelemy UTC-4,America/St_Kitts UTC-4,America/St_Lucia UTC-4,America/St_Thomas UTC-4,America/St_Vincent UTC-4,America/Tortola UTC-3,Etc/GMT+3 UTC-3,America/Cayenne UTC-3,America/Paramaribo UTC-3,Antarctica/Palmer UTC-3,Antarctica/Rothera UTC-2,Etc/GMT+2 UTC-2,America/Noronha UTC-2,Atlantic/South_Georgia UTC-1,Etc/GMT+1 UTC-1,Atlantic/Cape_Verde Depending on the search result, you can expect the following behavior: • If the value of the `timezone` attribute is

Function	Parameters	Description

		found in the predefined list of mapped values, it is provisioned in the specified format.
		
		Note
		When the conversion is set to `iana` output format, the value of the `timezone` attribute is converted to its default world region mapping value set for the system, which is the first matching timezone entry from the list. This could result in a changed timezone value during the initial provisioning, in which the `"outputFormat"` modifier is set to `iana` output format.
		
		• If there is not `timezone` attribute value in the specified source path or it is not found in the predefined list, the function returns the default value for the specified output format, as follows:
		  • for `iana` output format - the value `Europe/Berlin`
		  • for `sap` output format - the value `CET`
		
		EXAMPLE 1:
		
		In the following transformation example, function *convertTimezoneCode* will be applied to the timezone attribute values from the specified source path, converting them in `sap` output format.

Function	Parameters	Description

		For example, the time zone **America/Phoenix** will be provisioned as MSTNO.
		
		`{ "mappings": [ { "sourcePath": "$.timezone", "targetPath": "$.timezone", "functions": [ { "type": "convertTimezoneCode", "outputFormat": "sap" } ] } ] }`
		
		EXAMPLE 2:
		
		In the following transformation example, function *convertTimezoneCode* will be applied to the timezone attribute values from the specified source path, converting them in iana output format.
		
		For example, the time zone **AST** will be provisioned as America/Halifax, which is the default value set for the relevant timezone.
		
		`{ "mappings": [ { "sourcePath": "$.timezone", "targetPath": "$.timezone", "functions": [ { "type": "convertTimezoneCode", "outputFormat": "iana"`

Function	Parameters	Description

		<pre>}
		]
		}
		]
		}</pre>

Function	Parameters	Description

compositeId	• **separator**
	Required: Yes
	Possible values: : (colon)
	• **subId**
	Required: Yes
	Type: String; JSONPath expression
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function appends the value referred by the source path to the value of the `subId` parameter, separated by ":".
		
		Example
		Input JSON code before transformation:
		`{ "qualifierId": "johnsmith" }`
		
		Example
		Transformation using the function:
		`{ "sourcePath": "$.qualifierId", "targetPath": "$['composite_id.custom_separator.colon']", "functions": [ { "function": "compositeId", "separator": ":", "subId": "e0123456" } ] }, ...`
		
		Example
		After the function execution, the output JSON results to:
		`{ "composite_id.default_separator": "johnsmith:e0123456",`

Function	Parameters	Description
		"composite_id.custom_separator.colon": "johnsmith:e0123456", "composite_id.custom_separator.dash": "johnsmith-e0123456" }

Function	Parameters	Description

copyMapEntry	• **sourceKey**
	Required: Yes
	Type: String
	• **targetKey**
	Required: Yes
	Type: String
		This function copies a key-value pair from the source JSON and creates a similar one in the target JSON. The nelwy created pair consists of the specified `targetKey` String and the value copied from the initial pair. The two key-value pairs are written into the target system.
		
		EXAMPLE:
		
		For example, if the source entity contains the following roles:
		
		`{ "role": [{"roleName": "ROLE1"}, {"roleName": "ROLE2"}] }`
		
		After applying the function:
		
		`{ "sourcePath": "$.user.role", "optional": true, "targetPath": "$.groups", "preserveArrayWithSingleElement": true, "functions": [ { "function": "copyMapEntry", "sourceKey": "roleName", "targetKey": "value" } ] }`
		
		Two pairs with `targetKey` **`"value"`** are added to the target JSON and the result is:
		
		`{ "groups": [{"roleName": "ROLE1", "value":"ROLE1"}, {"roleName": "ROLE2", "value":"ROLE2"}] }`

Function	Parameters	Description

decode	• **algorithm**
	Required: Yes
	Possible values:
	• base32
	• base64
	• **skipPadding**
	Required: No
	Type: Boolean
	Possible values:
	• true
	• false
	Default value: false
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	• true
	• false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		The function **decode** is part of the Write transformation of some proxy systems (like AS ABAP).It decodes the string value specified by the sourcePath or sourceVariable mapping attribute, by using specified decoding algorithm.
		
		Function result: Byte array
		
		EXAMPLE:
		
		For example, if the input JSON code contains the following user name:
		
		`{ "USERNAME": "JOHN*SMITH/Junior" }`
		
		The base32 encoded result will be the following id:
		
		Example
		
		`{ "id": "JJHUQTRKKNGUSVCIF5FHK3TJN5ZA====" }`
		
		The *decode* function reads the **id** and converts it into a byte array. Afterward, the *toString* function reads this byte array and converts it into the original **USERNAME** string. The base32 padding symbols (==) are skipped.
		
		Example
		
		`// Write Transformation { "user": { "mappings": [ { "sourcePath": "$.id",`

Function	Parameters	Description

		<pre>"targetPath": "$.USERNAME",
		"functions": [
		{
		"function": "decode",
		"algorithm": "base32",
		"skipPadding": true
		},
		{
		"function": "toString"
		}
		]
		},
		...</pre>

Function	Parameters	Description

elementAt	• **index**
	Required: Yes
	Type: Integer
		This function is used to retrieve a specific element from an array based on its index. The index indicates the element you want to access.
		
		Using the **elementAt** function with index 0 in this example results in requesting the first email within an array of primary emails. After evaluating the sourcePath, it returns all primary emails. Applying the **elementAt** function with index 0 then retrieves the first primary email from this array.
		
		Code Syntax
		
		`{`
		
		`"condition":"$.emails[?(@.primary == true)].value != []",`
		
		`"sourcePath":"$.emails[?(@.primary == true)].value",`
		
		`"preserveArrayWithSingleElement":true,`
		
		`"optional":true,`
		
		`"targetPath":"$.email",`
		`"functions":[`
		`{`
		
		`"function":"elementAt",`
		
		`"index":0`
		`}`
		`]`
		`},`

Function	Parameters	Description

encode	• **algorithm**
	Required: Yes
	Possible values:
	  • base32
	  • base64
	• **skipPadding**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	Default value: false
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		The function **encode** is part of the Read transformation of some proxy systems (like AS ABAP). It encodes the value specified by the sourcePath or sourceVariable mapping attribute, by using specified encoding algorithm.
		
		The function can accept a Byte array or everything that has a string representation. The string is assumed in UTF-8 character encoding.
		
		Function result: String
		
		EXAMPLE:
		
		For example, if the input JSON code contains the following user name:
		
		`{ "USERNAME": "JOHN*SMITH/Junior" }`
		
		The base32 encoded result will be the following id:
		
		Example
		
		`{ "id": "JJHUQTRKKNGUSVCIF5FHK3TJN5ZA====" }`
		
		The *encode* function reads the **USERNAME** string and writes the encoded value into the **id** path. The base32 padding symbols (==) are skipped.
		
		Example
		
		`// Read Transformation { "user": {`

Function	Parameters	Description
		"mappings": [{ "sourcePath": "$.USERNAME", "targetPath": "$.id", "targetVariable": "entityIdSourceSystem", "functions": [{ "function": "encode", "algorithm": "base32", "skipPadding": true }] }, ...

Function	Parameters	Description

getMatchedRegexGroup	• **regex**
	Required: Yes
	Type: String
	• **groupIndex**
	Required: Yes
	Type: Integer
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function checks whether a given string matches the provided regular expression (regex), and returns the required group.
		
		For example, when the value of groupIndex is:
		• *0* – the function returns the entire string
		• Positive number – the function returns a specific group from the string. For instance, `groupIndex` = *3* will return the third group.
		
		Example
		Initial user data:
		`{ "distinguishedName": [ "CN=test10,OU=subUsers,OU=testUsers" ] }`
		
		Example
		Transformation in the source system:
		`{ "group": { "mappings": [ { ... "sourcePath": "$.distinguishedName[0]", "functions": [ { "function": "getMatchedRegexGroup", "regex": "(?`

Function	Parameters	Description

		<pre>i)cn=.*?,
		(.*?),OU=testUser
		s",
		
		"groupIndex": 1
		}
		],
		
		"targetPath": "$
		['urn:sap:cloud:s
		cim:schemas:exten
		sion:ad:2.0:User'
		]['nestedPath']"
		}
		]
		}</pre>
		Example
		Nested path extracted from the user DN, after the transformation:
		<pre>{
		
		"urn:sap:cloud:sc
		im:schemas:extens
		ion:ad:2.0:User":
		{
		
		"nestedPath":
		"OU=subUsers"
		}
		}</pre>

Function	Parameters	Description

manipulateDate	• **sourceDateFormat**
	Required: No
	Type: Date; Time
	• **targetDateFormat**
	Required: No
	Type: Date; Time
	• **years**
	Required: No
	Type: Integer
	• **months**
	Required: No
	Type: Integer
	• **days**
	Required: No
	Type: Integer
	• **hours**
	Required: No
	Type: Integer
	• **minutes**
	Required: No
	Type: Integer
	• **seconds**
	Required: No
	Type: Integer
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function converts one date format into another after JSON-Path transformations.
		
		Use cases:
		• A Java date format can be converted into another Java date format.
		Example: "**2018-02-28 11:00:00.000**" to "**02/28/2018**"
		• A date format based on *Unix Time Stamp* can be converted into a Java one. That means, if the source system stores a date as a number of milliseconds, after the transformations this number will be converted and written in the target system as a human readable date.
		Example: "**Date(1519809649123-0240)**" to "**2018-02-28 UTC+1**"
		
		Note
		Bear in mind the following restrictions about *Unix Time Stamp* format:
		• It is mainly applicable for SAP SuccessFactors connectors.
		• If the source date format contains a timezone (GMT, EST, ACT, etc.), after converting from *Unix Time Stamp*, the date will be displayed as a UTC offset.
		• During calculation, the timezone is ignored – the milliseconds are converted to a "pure"

Function	Parameters	Description
		date. The timezone is displayed (as UTC offset) but not taken into account. The *manipulateDate* function supports the following operations: • (**Java**) Incrementing the date by the "**+**" sign or when there is no sign • (**Java**) Decrementing the date by the "**–**" sign • (**Unix Time Stamp**) Converting a number of milliseconds into a human readable date **Note** The parameters `sourceDateFormat` and `targetDateFormat` accept values in short or full date & time format. For example: *yyyy-MM-dd'T'HH:mm:ss'Z'*, **`d MMM uuuu`**, or **`HH:mm dd/MM/yyyy`**. **Example** **Reads and writes the current date in standard Java date format** `{ "targetPath": "$.EmployeeType.ValidityPeriod.StartDate", "sourceVariable": "currentDate", "functions": [ { "function": "manipulateDate",`

Function	Parameters	Description

		"targetDateFormat" : "MM/dd/yyyy",
		
		"sourceDateFormat" : "yyyy-MM-dd HH:mm:ss.SSS",
		
		"years":
		
		"months":
		// You can also, for example, increment the date with 3 days and 2 hours
		
		"days": "3"
		
		"hours": "+2"
		
		"minutes":
		
		"seconds":
		}
		...
		}

		Example **Reads a given date in Unix Time Stamp format (in milliseconds) and writes the converted value in the target system as a standard Java date format** { "targetPath": "$.EmployeeType.ValidityPeriod.StartDate", "sourcePath": "$date", "functions": [{ "function": "manipulateDate", "sourceDateFormat": "Date(milliseconds)",

Function	Parameters	Description

		<pre>"targetDateFormat": "yyyy-MM-dd HH:mm:ss.SSS"
		}
		...
		}</pre>

Function	Parameters	Description

matchRegex	• **regex**
	Required: Yes
	Type: String
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function checks whether a given string matches the provided regular expression and returns a Boolean result.
		
		Example
		Checks whether the value of attribute "COMPOSITE_PRIVILEGE" matches the regular expression "*_COMP", and assigns the result (true or false) to attribute "composite".
		
		`{ "mappings": [ { "sourcePath": "$.PRIVILEGES", "targetPath": "$.groups", "functions": [ { "function": "matchRegex", "regex": ".*_COMP", "applyOnAttribute": "COMPOSITE_PRIVILEGE", "assignToAttribute": "composite" } ] } ] }`

Function	Parameters	Description

putIfAbsent	• **key**
	Required: Yes
	Type: String
	• **defaultValue**
	Required: Yes
	Type: String; Array; Integer; another value type
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function works on user attributes of type array (list of elements), as each element consists of key-value pairs. If an element key misses a value, the putIfAbsent function will set a default value for this key.
		
		Example
		This function is part of the default **Identity Authentication** target and proxy write transformation. In this case, the user attribute "**addresses**" is a list of addresses. The **putIfAbsent** function is applied on every single address (element) of this list.
		
		`...`
		`{`
		`"sourcePath": "$.addresses",`
		`"targetPath": "$.addresses",`
		`"preserveArrayWithSingleElement": true,`
		`"defaultValue": [],`
		`"optional": true,`
		`"functions": [`
		`{`
		`"function": "putIfAbsent",`
		`"key": "type",`
		`"defaultValue": "work"`
		`}`
		`]`
		`},`
		`...`

Function	Parameters	Description

putIfPresent	• **key**
	Required: Yes
	Type: String
	• **defaultValue**
	Required: Yes
	Type: String; Array; Integer; another value type
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function works on user attributes of type **array** (list of elements), as each element consists of *key-value* pairs.
		
		• If an element key has a value but it's different than the default one, the **putIfPresent** function will set a default value for this key.
		• If an element has a value and it's equal to the default one, the **putIfPresent** function keeps this value as is.
		
		Example
		This function is part of the default **Identity Authentication** target and proxy write transformation. In this case, the user attribute "**addresses**" is a list of addresses. The **putIfPresent** function is applied on every single address (element) of this list.
		
		`...`
		`{`
		`"sourcePath": "$.addresses",`
		`"targetPath": "$.addresses",`
		`"preserveArrayWithSingleElement": true,`
		`"defaultValue": [],`
		`"optional": true,`
		`"functions": [`
		`{`
		`"condition": "(@.type NIN ['work', 'home'])",`
		`"function": "putIfPresent",`

Function	Parameters	Description
		"key": "type", "defaultValue": "work" }] }, ...

Function	Parameters	Description

randomPassword	• **passwordLength**
	Required: Yes
	Type: Integer
	• **minimumNumberOfLowercaseLetters**
	Required: Yes
	Type: Integer
	• **minimumNumberOfUppercaseLetters**
	Required: Yes
	Type: Integer
	• **minimumNumberOfDigits**
	Required: Yes
	Type: Integer
	• **minimumNumberOfSpecialSymbols**
	Required: Yes
	Type: Integer
	• **specialSymbols**
	Required: No
	Possible values: List of allowed special symbols (no comma separation)
	Default value: ~!@#$%^&*()_+
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function generates a random password. It picks characters from four character sets - digits, lowercase letters, uppercase letters, and special symbols.
		
		Bear in mind the following tips:
		• The password length must be supplied along with the number of characters from each set. If a value "**0**" is supplied for a given parameter, no characters will be picked from the corresponding character set.
		• If the summed up number of characters (from all sets) exceeds the total password length, the function execution will result in error.
		• If the summed up number of characters (from all sets) is less than the total password length, the remaining characters will be randomly picked from all character sets.
		• A custom character set is supplied by the `specialSymbols` parameter.
		• If a custom set of special symbols is supplied, the parameter `minimumNumberOfSpecialSymbols` cannot have a value of "**0**".
		
		Note
		The **randomPassword** function does not require `sourcePath`, `sourceVariable`, or `constant` to be specified in the mapping.
		
		Example

Function	Parameters	Description

		{
		"user": {
		"mappings": [
		{
		"targetPath": "$.password",
		"functions": [
		{
		"function": "randomPassword",
		"passwordLength": 16,
		"minimumNumberOfLowercaseLetters": 4,
		"minimumNumberOfUppercaseLetters": 4,
		"minimumNumberOfDigits": 4,
		"minimumNumberOfSpecialSymbols": 4,
		"specialSymbols": ",.<>/?~`!@#"
		}
		...
		}

Function	Parameters	Description

renameMapEntry	• **sourceKey**
	Required: Yes
	Type: String
	• **targetKey**
	Required: Yes
	Type: String
		This function reads the `sourceKey` String from the source JSON and renames it with the given `targetKey` String in the target JSON.
		
		EXAMPLE:
		
		For example, if the source entity contains the following roles:
		
		`{ "role": [{"roleName": "ROLE1"}, {"roleName": "ROLE2"}] }`
		
		After applying the function:
		
		`{ "sourcePath": "$.user.role", "optional": true, "targetPath": "$.groups", "preserveArrayWithSingleElement": true, "functions": [ { "function": "renameMapEntry", "sourceKey": "roleName", "targetKey": "value" } ] }`
		
		The `sourceKey` String in the target JSON is replaced with the one given in the `targetKey` and the result is:
		
		`{ "groups": [{"value":"ROLE1"}, {"value":"ROLE2"}] }`

Function	Parameters	Description

replaceString	• **target**
	Required: Yes
	Type: String; number
	• **replacement**
	Required: Yes
	Type: String; number
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function reads strings from the source system and then replaces each substring that matches the value of the target parameter with the replacement one.
		
		For example, let's say the source system contains a string "*National College of Linguistics and History*". The `target` substring is "**National**" and the `replacement` substring is "**European**". Then, in the target system the main string will be written as "*European College of Linguistics and History*".
		
		Example
		
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "replaceString", "target": "iag", "replacement": "ips" } ] } ... }`

Function	Parameters	Description

replaceFirstString	• **regex**
	Required: Yes
	Type: String; number
	• **replacement**
	Required: Yes
	Type: String; number
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function replaces the first substring of a given string that matches the provided regex with the string in replacement.
		
		Example
		
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "replaceFirstString", "regex": "14\\d{1}", "replacement": 123 } ] } ... }`

Function	Parameters	Description

replaceLastString	• **regex**
	Required: Yes
	Type: String; number
	• **replacement**
	Required: Yes
	Type: String; number
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function replaces the last substring of a given string that matches the provided regex with the string in replacement.
		
		Example
		
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountNam e[0]", "targetPath": "$.userName", "functions": [ { "function": "replaceLastStrin g", "regex": "14\ \d{1}", "replacement": 123 } ] } ... }`

Function	Parameters	Description

replaceAllString	• **regex**
	Required: Yes
	Type: String; number
	• **replacement**
	Required: Yes
	Type: String; number
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function replaces each sub-string of the given string that matches the provided regex with the string in replacement.
		
		Example
		
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "replaceAllString", "regex": "14\\d{1}", "replacement": 123 } ] } ... }`

Function	Parameters	Description

resolveEntityIds	**entityType**
	Required: No
	Possible values:
	• `user`
	• `group`
	Default value: `user`
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	• true
	• false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
	• **sourceSystemName**
	Required: No
	Type: String
	• **targetSystemName**
	Required: No
	Type: String
		This function resolves the value of a source system attribute to an existing back-end key in the target system. It should be used only in the transformation mappings of the target system.
		
		For example, it can resolve the value of a source system member attribute to the ID of an existing SCIM resource that represents this member in a SCIM target system.
		
		Example
		`{`
		`"sourcePath": "$.member",`
		`"preserveArrayWithSingleElement": true,`
		`"optional": true,`
		`"targetPath": "$.members[?(@.value)]",`
		`"functions": [`
		`{`
		`"entityType": "group",`
		`"function": "resolveEntityIds"`
		`}`
		`]`
		`...`
		`}`
		
		The `sourceSystemName` and the `targetSystemName` parameters are typically used within this function to resolve group members.
		
		In the following example, we assume that you have created two

Function	Parameters	Description
		source systems reading entities from one and the same user store (for example, Microsoft Entra ID). You provision users from *SourceSystem1* and groups from *SourceSystem2* to one and the same target system. By specifying the `sourceSystemName` as *SourceSystem1*, the user IDs of the group members in *SourceSystem2* will be resolved against the user IDs in the *SourceSystem1*. **Code Syntax** `"functions": [ { "sourceSystemName": "SourceSystem1", "function": "resolveEntityIds" } ] ...`

Function	Parameters	Description

splitStringToArray	• **separator**
	Required: Yes
	Type: String
		This function splits the initial String using the defined separator and produces as a result an array of Strings or objects.
		
		In the following examples, function *splitStringToArray* is applied to the `sourcePath`, read from the source system. Based on the `targetPath` defined, the initial String will be split into array of Strings or objects.
		
		Example 1
		
		In the first example, the initial String we use is:
		
		`"countries": "Serbia,Germany,Spain"`
		
		The transformation using the function is the following:
		
		`{ "sourcePath": "$.countries", "targetPath": "$.countryList", "functions": [ { "function": "splitStringToArray", "separator": "," } ] }`
		
		After the function execution, the output results to the following array of Strings:
		
		`"countryList": [ "Serbia", "Germany",`

Function	Parameters	Description

```
        "Spain"
    ],
```

Example 2

In the second example, we use the same initial String:

```
"countries":
"Serbia,Germany,Spai
n"
```

In this case, the `targetPath` in the transformation using the function supports multiple values:

```
 {

"sourcePath":
"$.countries",

"targetPath":
"$.countryList[?
(@.name)]",

"functions": [

{

    "function":
"splitStringToArray"
,

    "separator":
","

}
                ]
            },
```

After the function execution, the output results to the following array of objects:

```
"countryList": [
        {
            "name":
"Serbia"
        },
        {
            "name":
"Germany"
        },
        {
```

Function	Parameters	Description
		<pre>"name": "Spain" }], </pre>

substring	• **beginIndex**
	Required: Yes
	Type: Integer
	• **endIndex**
	Required: No
	Type: Integer
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function returns a string if `endIndex` is not provided. It begins at the specified `beginIndex` and extends either to the character at index `endIndex - 1` or to the end of this string.
		
		Example
		<pre>{ "user": { "mappings": [{ "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [{ "function": "substring", "beginIndex": 3, "endIndex": 5 }] } ... }</pre>

Function	Parameters	Description

toString	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function accepts a Byte array or a string representation. The string is assumed in UTF-8 character encoding. Function result: **String**.
		
		To see a relevant example, go to function encode and decode.

toUpperCaseString	• **locale**
	Required: No
	Possible values: Abbreviation of locale, such as `de_DE`, `ja_JP`, `ru_RU` and so on.
	Default value: `en_EN`
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function converts all the characters in the given string to upper case, using the provided locale, or if nothing defined – English.
		
		Example
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "toUpperCaseString", "locale": "en_EN" } ] } ... }`

Function	Parameters	Description

toLowerCaseString	• **locale**
	Required: No
	Possible values: Abbreviation of locale, such as `de_DE`, `ja_JP`, `ru_RU` and so on.
	Default value: `en_EN`
	• **condition**
	Required: No
	Type: String
	• **applyOnElements**
	Required: No
	Type: Boolean
	Possible values:
	  • true
	  • false
	• **applyOnAttribute**
	Required: No
	Type: String
	• **assignToAttribute**
	Required: No
	Type: String
		This function converts all the characters in the given string to lower case, using the provided locale, or if nothing defined – English.
		
		Example
		`{ "user": { "mappings": [ { "sourcePath": "$.sAMAccountName[0]", "targetPath": "$.userName", "functions": [ { "function": "toLowerCaseString", "locale": "en_EN" } ] } ... }`

1.3.6.4 Transformation Variables

System variables specify particular attributes of the read and written entities. The variables are used for temporary saving of data in the transformation mappings of the provisioning systems. They do not have representation in the output JSON file. You can define a variable in the context of one provisioning system and specific entity. The value of the defined variable cannot be used in another provisioning system or entity.

The table below includes information about variables that have specific behavior:

Transformation Variables

Variable	Definition & Example	System Types
assignGroup	An optional variable, which enables you to assign groups to a user in the target system. It can be used for standard provisioning with or without configured bulk operation on the target, and real-time provisioning. To enable the group assignment, you need to modify the target system transformation by adding a mapping under the user resource containing the following configuration parts: • **Condition** - Defines for which users the condition will apply. For example, all users with emails. • **Constant** - Holds the IDs of the groups in the target system. Currently, you can only identify groups by ID. • **targetVariable** - Specifies whether you want to assign users to groups or unassign users from groups. Example `{ "user":{ "mappings":[ <Existing transformation> { "condition":"($.emails EMPTY false)", "constant":[ { "id":"00f8ab94-a732-48fa-9169-e51f87b8dcd5" }, { "id":"01231139-4711-4a28-8f9d-6745843ef716" } ], "targetVariable":"assignGroup" } ] }, "group":{ "mappings":[` This mapping will result in assigning all users with emails to two groups in a target system. For more information, see Enabling Group Assignment [page 2445].	Target systems

Variable	Definition & Example	System Types
entityIdSourceSystem	Mandatory for every read transformation (in source and proxy systems). It specifies which attribute of a read entity to be considered as a unique ID in the source system. Use this mapping with caution, as it can overwrite the value of the ID returned by the source system. It is not recommended to change the attribute specified in the source path of the mapping. Such change may cause incorrect deletion of entities from the target system. In case you should change the mapping for the variable, you must reset the source system. For more information, see Reset Identity Provisioning System [page 2485]. **Example** `{ "targetVariable": "entityIdSourceSystem", "sourcePath": "$.name" }`	• Source systems • Proxy systems
entityIdTargetSystem	Mandatory for every write transformation (in target and proxy systems). It specifies which attribute of a written entity to be considered as a unique ID in the target system. This variable is defined by the target system according to the system response during entity creation, or is read from the Identity Provisioning database during entity modification or deletion. It is not recommended to change the attribute specified in the target path of the mapping. Such change may cause incorrect deletion of entities from the target system. In case you should change the mapping for the variable, you must reset the target system. For more information, see Reset Identity Provisioning System [page 2485]. **Example** `{ "sourceVariable": "entityIdTargetSystem", "targetPath": "$.id" }`	• Target systems • Proxy systems

Variable	Definition & Example	System Types
entityBaseLocation	Mandatory only for read transformations in proxy systems. It contains the proxy application URL featuring the entity type endpoint: **https://ipsproxy<proxy_provider_account>-<consumer_account>.<neo_landscape>:443/ipsproxy/api/v1/scim/<system_ID>/Users** Example `{ "sourceVariable": "entityBaseLocation", "targetVariable": "entityLocationSourceSystem", "targetPath": "$.meta.location", "functions": [ { "type": "concatString", "suffix": "${entityIdSourceSystem}" } ] }`	Proxy systems
entityLocationSource-System	Mandatory only for read transformations in proxy systems. It contains the proxy application URL featuring the SCIM 2.0 resource endpoint for an entity: **https://ipsproxy<proxy_provider_account>-<consumer_account>.<neo_landscape>:443/ipsproxy/api/v1/scim/<system_ID>/Users/<user_ID>** Example `"sourceVariable": "entityBaseLocation", "targetVariable": "entityLocationSourceSystem", "targetPath": "$.meta.location", "functions": [ { "type": "concatString", "suffix": "${entityIdSourceSystem}" } ] }`	Proxy systems

Variable	Definition & Example	System Types
currentDate	An optional variable, which contains the current date, in format: *yyyy-MM-dd HH:mm:ss.SSS* You can configure this variable by using property `ips.date.variable.format`, according to the Java Class DateTimeFormatter . **Example** `{ "targetPath": "$.PersonalDetails.ValidityPeriod.StartDate", "sourceVariable": "currentDate", "functions": [ { "type": "manipulateDate", "targetDateFormat": "yyyy-MM-dd" } ] }`	• Source systems • Target systems • Proxy systems

Variable	Definition & Example	System Types
unassignGroup	An optional variable, which enables you to remove the group assignments of a deleted user from the source system. In that case, you need to modify the target system transformation by adding a mapping under the user resource containing the following configuration parts:. • **Constant** - Holds the IDs of the groups in the target system which will be updated. Currently, you can only identify groups by ID. • **targetVariable** - Use **`"unassignGroup"`** to specify that you want to unassign users from the defined groups. • **scope** - Use **`"deleteEntity"`** to define that the deleted user from the source system should be persisted in the target system. **Example** `{ "constant": [ { "id": "groupID" } ], "targetVariable": "unassignGroup", "scope": "deleteEntity" }` This mapping will result in updating the assignments to the defined group in the target system. When using the group unassignment for users that are deleted from the source system, these are two possible scenarios based on the system where the user was created and the value of the property `ips.delete.existedbefore.entities`. For more information, see Enabling Group Assignment [page 2445].	Target systems

1.3.6.5 Transformation Conditions

A condition defines a JSON filter expression that can be applied to entity types (such as users, groups, and roles) or within attribute mappings. It can be combined with strings, constants, variables, and functions, or used within functions.

You can add conditions in both source and target system transformations. When applied in the source transformation, entities that do not meet the condition are skipped after being read. When applied in the target transformation, entities that do not meet the condition are skipped before being written.

You can define conditions using the JSONPath specification in the Identity Provisioning editors: JSON editor and Graphical editor.

Operators and Checks	Description
==	Left-hand value is equal to right-hand value. For example: `"condition": "$.emails[?(@.primary == true)].value == []",` This condition checks if the user has no primary email defined. It evaluates to `true` if the `emails` array contains no entry where `primary` is set to `true`. This condition is used in the default write transformations of SAP Commerce Cloud, where if the user has no primary email, the first email in the list is used instead. The following explains each part of the filter expression: • `$` - Indicates the starting point for the JSONPath expressions. • `emails` - Accesses the emails array within the user entity. • `[?()]` - Starts a filter expression to evaluate the array. • `@` - Refers to the current element within the array. • `@.primary == true` - Filters the array to retrieve only the elements marked as the primary email. • `.value` - After applying the filter condition, this extracts the actual email address. • `== []` - Checks if the value on the left-hand side is equal to an empty array `[]`. → Tip Use this pattern `[?(@. ...)]` for filtering elements within an array based on defined conditions.

Operators and Checks	Description
`!=` or `!==`	Left-hand value is not equal to right-hand value. For example: `"condition": "$.name.familyName != 'Smith'",` This condition checks if the user's `familyName` is not equal to `Smith`. Only users whose `familyName` is different from `Smith` fulfill this condition.
`=~`	Left-hand value matches the regular expression on the right-hand side. For example: `"condition": "$.emails[0].value =~ /.*@example.com/",` This condition checks if the user's first email in the `emails` array ends with `@example.com`. Only users whose first email (`emails[0].value`) contains this domain fulfill this condition. • `/` - Marks the beginning and the end of a regex. • `.*` - Matches any sequence of characters, including an empty sequence.
`&&`	AND: Returns `true` if both expressions are `true`. For example: `"condition": "($.user.validityPeriod.startDate <= '${currentDate}') && ($.user.validityPeriod.endDate > '${currentDate}')",` This condition checks whether the user is within their validity period. Only users whose validity period includes the current date will meet this condition, indicating that they are considered active. This condition is used in the default read transformations of SAP S/4HANA Cloud Public Edition source system to process only active users.

Operators and Checks	Description
`||`	OR: Returns `true` if at least one expression is `true`. For example: `"condition": "((('%c4c.group.prefix%' === 'null') || ($.groups[?(@.display =~ /%c4c.group.prefix%.*/)] empty false)) && $.userName empty false && ($.userType === 'Employee' || $.userType === 'employee'))",` Simplified pattern: `(<group prefix check> || <group presence check>) && <username presence check> && (<user type 'Employee' check> || <user type 'employee' check>)` This condition checks if the group prefix is null, or if there is at least one group in the user's groups array whose display name starts with the specified prefix. Additionally, it ensures that the `userName` is not empty and that the `userType` is either `"Employee"` or `"employee"`, allowing case insensitivity in the first letter only. This condition is used in the default write transformations of SAP Sales Cloud and SAP Service Cloud connector version 4 target system.
`empty true`	Left-hand value is considered empty (null, empty string, empty array). For example: `"condition": "($.emails EMPTY true) \|\| isValidEmail($.emails[0].value)",` This condition checks if an email is either missing (that is, the `emails` array is empty) or the first email in the array is valid. This condition is used in the default write transformations of SAP Advanced Workflow target system to ensure that an email is either provided and valid or missing.

Operators and Checks	Description
`empty false`	Left-hand value is not considered empty. For example: `"condition": "($.emails EMPTY false) && ($.userName EMPTY false) && isValidEmail($.emails[0].value)",` This condition checks if all parts are `true`. It expects at least one email to be present, the `userName` field to be filled, and the first email address in the `emails` array to be valid. This condition is used for the user entity in the default write transformations of Identity Authentication version 2 and Local Identity Directory target systems.

The following examples show how you can use conditions for filtering users based on group assignments.

Check if Users are Assigned to a Group with Specific Prefix

Example

Code Syntax

```
{
   "user":{
      "condition":"$.groups[?(@.display =~ /ABC.*/)] empty false",
```

This condition evaluates to `true` if the user is a member of at least one group whose display name begins with ABC.

Check if Users are Not Assigned to a Particular Group

Example

Code Syntax

```
{
   "user":{
      "condition":"$.groups EMPTY true || $.groups[?(@.display === 'XYZ' )]
empty true",
```

This condition evaluates to `true` if the user has no group memberships at all, or if they are not a member of any group named XYZ. You can use it to exclude (skip) users who are specifically assigned to the XYZ group.

Check if Users are Assigned to One or Two Particular Groups

Example

Code Syntax

```
{
   "user":{
      "condition":"($.groups EMPTY false) && ( ($.groups[?(@.display
===ABC' )] != []) || ($.groups[?(@.display ===XYZ')] != []))",
```

This condition evaluates to `true` if the user has at least one group assigned to them, and if they are a member of either the ABC group or the XYZ group or both.

Check for Particular Custom Attribute of Users

Example

Code Syntax

```
"sourcePath": "$['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']
['attributes'][?(@.name=='customAttribute1')]['value']",
```

While not a condition itself, this source path expression can be used to retrieve the value of a given custom attribute (`customAttribute1`) from the user's data. It works by filtering the `attributes` array to find the attribute with the name `customAttribute1`, and then returns the value of that attribute.

Assign User to a Group Based on UserName

Example

Code Syntax

```
{
    "condition": "$.userName =~ /.*explorer.*/",
    "constant": "Explorers",
    "targetPath": "$.groups[0].value"
},
{
    "condition": "$.userName =~ /.*scifi.*/",
    "constant": "Scientists",
    "targetPath": "$.groups[1].value"
}
```

This configuration assigns users to groups based on their `userName`: those with `explorer` in their `userName` are assigned to the `Explorers` group, and those with `scifi` are assigned to the `Scientists` group.

> **Note**
>
> This mapping works for systems that support group assignment via the user entity, for example, Identity Authentication SCIM API version 1. Make sure that the `group ID` in the target system matches the value defined in the constant field (in this case, `Explorers` and `Scientists`).

1.3.6.6 Transformation Examples

The following examples explain how transformations work.

Basic Transformation

The basic transformation copies all attributes from the input JSON messages to the output JSON ones.

> **Code Syntax**

```
{
    "sourcePath": "$",
    "targetPath": "$"
},
```

Source, Intermediate, and Target Data

In this example, the source system JSON data contains the **sn[0]** attribute. The read transformation converts this attribute to **name.familyName** in the intermediate JSON data. Then, the write transformation reads the **name.familyName** attribute and maps it to **name.familyName** in the target system.

Source entity data (from Microsoft Active Directory)

```
{
    "sAMAccountName": ["jsmith"],
    "mail": ["john.smith@company.com"],
    "givenName": ["John"],
    "sn": ["Smith"],
    "memberOf": ["group1"],
    "memberOf_2": ["group21", "group22"],
    "memberOf_3": ["group31", "group32", "group33"]
}
```

Read transformation (intermediate JSON Data)

```
{
    "user": {
        "mappings": [
...
            {
                "sourcePath": "$.%ldap.attribute.user.id%[0]",
                "targetVariable": "entityIdSourceSystem",
                "correlationAttribute": true
            },
            {
                "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
                "constant": "",
                "targetVariable": "nestedPathRegex",
                "functions": [
                    {
                        "function": "concatString",
                        "prefix": "(?i)cn=.*?,(.*?)",
                        "suffix": ",%ldap.user.path%"
                    }
                ]
            },
            {
                "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
                "sourcePath": "$.%ldap.attribute.user.id%[0]",
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:User']['nestedPath']",
                "functions": [
                    {
                        "function": "getMatchedRegexGroup",
                        "regex": "${nestedPathRegex}",
                        "groupIndex": 1
                    }
                ],
                "defaultValue": ""
            },
            {
                "sourcePath": "$.sAMAccountName[0]",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.displayName[0]",
                "optional": true,
                "targetPath": "$.displayName"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.mail[0]",
```

```
                "optional": true,
                "targetPath": "$.emails[0].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.givenName[0]",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.sn[0]",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.memberOf",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.groups[?(@.value)]"
            },
...
```

Write transformation (intermediate JSON Data)

```
{
    "user": {
        "condition": "($.emails.length() > 0) && ($.name.familyName EMPTY
false)",
        "mappings": [
            {
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.corporateGroups"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "constant":
"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
                "targetPath": "$.schemas[1]"
            },
            {
                "sourcePath": "$.userName",
                "optional": true,
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.emails[*].value",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails[?(@.value)]"
            },
            {
                "sourcePath": "$.userType",
                "optional": true,
                "targetPath": "$.userType"
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
```

```
            },
            {
                "sourcePath": "$.name.middleName",
                "optional": true,
                "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.displayName",
                "optional": true,
                "targetPath": "$.displayName"
            },
...
```

Target entity data (result in Identity Authentication)

```
{
    "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:User",
        "urn:ietf:params:scim:schemas:extension:enterprise:2.0:User"
    ],
    "id": "P000100",
    "userName": "jsmith",
    "name": {
        "familyName": "Smith",
        "givenName": "John"
    },
    "emails": [
        {
            "value": "john.smith@company.com",
            "primary": "true",
            "type": "work"
        }
    ],
    "groups": [
        {
            "value": "group1"
        }
    ],
    "groups_2": [
        {
            "value": "group21"
        },
        {
            "value": "group22"
        }
    ],
    "groups_3": [
    {
            "value": "group31"
        },
        {
            "value": "group32"
        },
        {
            "value": "group33"
        }
    ]
}
```

For more information about condition examples, see Transformation Conditions.

1.3.6.7 Transformation Editors

Identity Provisioning provides graphical and JSON text editor for managing provisioning system transformations.

Graphical Editor

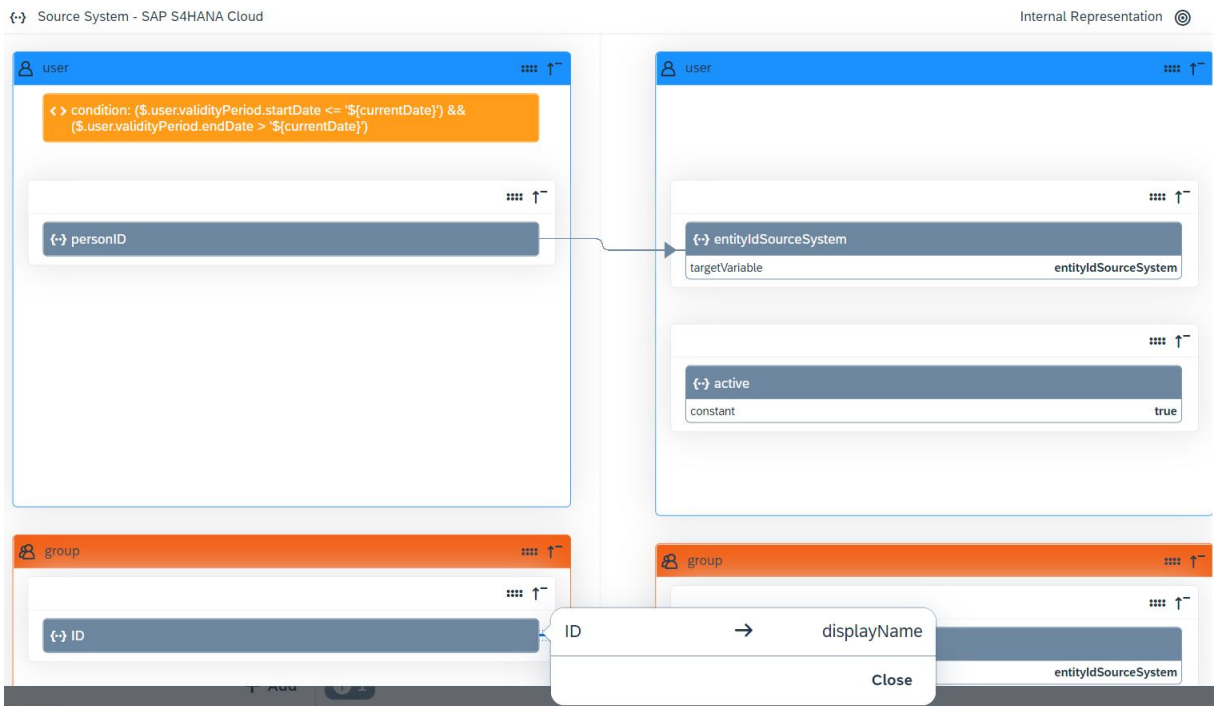
This editor allows you to graphically model the entities (users, groups, roles) and their content (attribute mappings and transformation expressions, like conditions, functions, constants, and others). It offers the following advantages:

- Visualization
  Entities are organized in colored boxes. Every entity has a dedicated color. Users are always blue, groups are orange and roles are green. Source and target path attributes are displayed horizontally (side-by-side). They are connected with an arrow which indicates the direction of reading and writing the data. Color coding makes it easy to identify specific configurations. Ignored entities are greyed out, skipped operations and conditions are displayed in orange.
- Simplification
  Typing code and following JSON syntax rules are no longer needed, except in cases when conditions are defined. Expressions and functions along with their possible values are prefilled and available for selection in dropdown lists. The editor takes care of adding the dot notation, that is, separating child elements with a period (.), enclosing string values within double quotes, prepending the dollar sign ($) to the JSONPath expression.
- Validation
  The JSON validator and the preview ensure that the input is in the expected format.

> ⓘ Note
>
> The graphical editor is available only for Identity Provisioning tenants running on SAP Cloud Identity infrastructure. It is the default editor.

> **Note**
>
> By default, the transformation opens in the graphical editor. However, the availability of the graphical editor depends on the total number of mappings across all entities. The JSON editor is always available.
>
> - 500 mappings or fewer: Both the graphical and JSON editors are available, and you can switch between them.
> - More than 500 mappings: The transformation can be viewed and edited only in the JSON editor. Switching to the graphical editor is not supported.

The following interactive screenshot shows the main elements of the graphical editor. Hover over the image and click highlighted areas for more information.



- #unique_111/unique_111_Connect_42_subsection-im0 [page 507]
- #unique_111/unique_111_Connect_42_subsection-im8 [page 507]
- #unique_111/unique_111_Connect_42_subsection-im1 [page 507]
- #unique_111/unique_111_Connect_42_subsection-im9 [page 507]

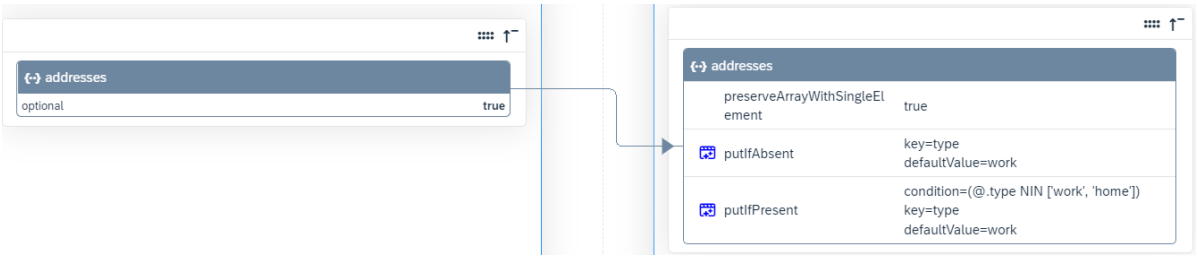
Hover over each element for a description. Click the element for more information.

The following example illustrates how the address attribute mapping from the Identity Authentication write transformation is displayed in the graphical editor. Compare the same attribute with its representation in the JSON editor below.

Attribute Mapping in Graphical Editor



The source path attribute **addresses** in the internal representation (on the left-hand side) and the target path attribute **addresses** in the target system (on the right-hand side) are displayed horizontally. The arrow shows the direction of reading and writing the data. The transformation expressions and functions are listed under the respective `sourcePath` and `targetPath` attribute they are applicable for.

JSON Editor

This editor allows you to work with entities and their transformation mappings in text mode. To add or modify transformations, you need to type. You can also perform operations like select, cut, copy, paste and others. The editor provides line numbering, syntax coloring and syntax validation.

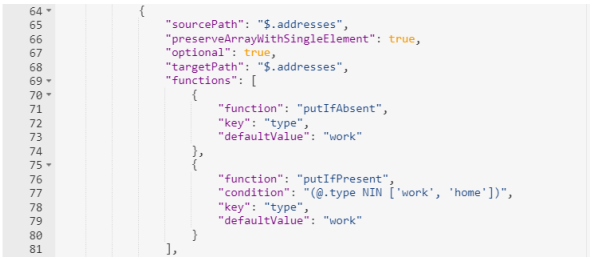
The following example illustrates how the address attribute mapping from the Identity Authentication write transformation is displayed in the JSON editor:

Attribute Mapping in JSON Editor

The source path attribute **addresses** in the internal representation and the target path attribute **addresses** in the target system are displayed vertically - one below the other.

The transformation expressions and functions are listed in individual lines below the respective `sourcePath` and `targetPath` attribute they are applicable for.

Syntax coloring and syntax validation are enabled by default.



```
64      {
65          "sourcePath": "$.addresses",
66          "preserveArrayWithSingleElement": true,
67          "optional": true,
68          "targetPath": "$.addresses",
69          "functions": [
70              {
71                  "function": "putIfAbsent",
72                  "key": "type",
73                  "defaultValue": "work"
74              },
75              {
76                  "function": "putIfPresent",
77                  "condition": "(@.type NIN ['work', 'home'])",
78                  "key": "type",
79                  "defaultValue": "work"
80              }
81          ],
```

Although the graphical and the JSON editors differ in the user experience they provide, other tasks, such as: export and reset transformations remain the same.

1.3.7 Users

Users in SAP Cloud Identity Services fall into three categories: administrators, end users, and technical users.

Administrators

SAP Cloud Identity Services distinguish between two types of administrators: **user administrator** and **system administrator**.

- User administrators are real persons. They manage tenant configurations, applications, corporate identity providers, identity provisioning, users, and groups. The initial administrator of SAP Cloud Identity Services tenants is created as a user administrator.
- System administrators are technical users. They are used for establishing system-to-system communication in provisioning scenarios, accessing real-time provisioning and proxy system APIs, as well as accessing tenant API for running Identity Provisioning jobs. System administrators can also act as user administrators because they have the same authorizations.

End Users

End users use business applications that consume Identity Authentication as identity provider. The service authenticates the users with credentials maintained in Identity Authentication or delegates the authentication request to a 3rd-party identity provider. End users are initially created, imported, or provisioned to the user store of SAP Cloud Identity Services.

There are six user types of end users:

User Type	Description
Customer	External users that are customers for the company. They may need access to some applications.
Employee	Internal company users, mainly users with long-term contracts.

User Type	Description
Partner	External users from a partner company that will need some kind of access.
Public	External users that are not controlled by the company. For example, self-registered.
External	External users that can be a temporary hired employees that need access to some applications, or external users that need access to learning materials and training managed by the company.
Onboardee	An employee user that needs a different authentication, because, for example the user may not exist in the corporate identity provider.
Alumni	External users that were once employed by the company but now they are no more part of it. They may need some kind of access.

Technical Users

Technical users are non-human identities that enable automated system-to-system communication and integration. Unlike administrators and end users, technical users authenticate using credentials such as secrets or certificates rather than passwords. Technical users are managed separately in the administration console via the *Technical Users* tile that appears under *Users & Authorizations*. The following prerequisites must be met, so that an administrator or technical user can manage the technical users:

- You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].
- The administrator or end user is assigned with the respective authorization policy, depending on the tasks they need to perform. For more information, see Configure Technical User Authorizations [page 2318].

> → Remember
>
> The minimal authorization policy required for the creation of a technical user is `CREATE_TECHNICAL_USERS`. The `MANAGE_TECHNICAL_USERS` allows all CRUD operations with a technical user.

For more information about how to create and manage the technical users, see Managing Technical Users [page 2329].

1.3.8 Agents

Agent identity represents AI and automation agents in SAP Cloud Identity Services. Agents can authenticate, receive authorization, and be managed like human users while retaining agent-specific capabilities and security controls.

> ⚠ Caution
>
> This page is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available to users outside of this program.

Agent identity combines multiple identity and access management (IAM) artifacts to provide comprehensive identity management for agents within SAP-centric environments.

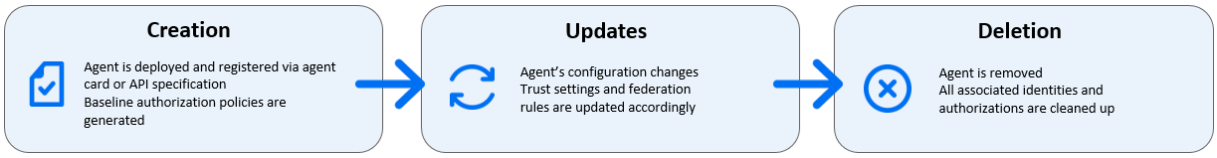
When an agent is built in Joule Studio, the agent automatically appears as an agent identity in the SAP Cloud Identity Services administration console. This allows user administrators to review the agent's authorizations and define who can access the agent.

In development landscapes, Joule Studio includes a feature that automatically assign access, reducing the need to contact user administrators for routine development tasks.

From an identity and access management perspective, an agent is an application registered in SAP Cloud Identity Services. Each deployed agent appears in the *Agents* tile of the SAP Cloud Identity Services administration console, where you can review its authorization policies, inspect which APIs it can call, and control which users or groups can invoke it.

You can't create or delete agents through the administration console. The SAP platform automatically manages their lifecycle in response to deployment events. When an agent is deployed, SAP Cloud Identity Services registers it using the agent's own metadata (its agent card or API specification) and generates baseline authorization policies at that point. When the agent's configuration changes, the system updates trust settings and federation rules in a controlled, traceable manner. When an agent is removed, the system fully cleans up

all associated identities and authorizations. To control which users or user groups can invoke an agent, use the *Agents* tile in the administration console.



Lifecycle of an Agent

SAP supports three categories of agents, each with a different level of administrator control:

- LOB agents
  The system provisions LOB agents as part of SAP line-of-business solutions such as SAP S/4HANA or SAP SuccessFactors. You can adjust authorization rules for these agents but cannot modify the agent registration itself.
- Custom agents
  Customers or partners build agents, for example using Joule Studio. The full range of configuration options is available, including trust settings and federation rules.
- Third-party agents
  Third-party agents are external AI tools that connect to the SAP landscape through the agent gateway. They authenticate and authorize against SAP Cloud Identity Services in the same way as SAP-native agents.

The system manages authorizations in two phases for increased security:

- Central Authorization in SAP Cloud Identity Services: Defines who can access an agent. This allows you to restrict agent access and provides visibility into the authorizations the agent has.
- Principal Propagation: The agent works on behalf of the current user. Each application and back end checks the user's authorizations, ensuring that the agent can only access what the user has permission to access.

This two-phase approach ensures security even when workflows span multiple runtime types.

Agents and Assistants

In Joule, an assistant is a higher-level AI entity that translates user intent into actions by coordinating agents. An assistant and each agent it invokes are separate registered identities in SAP Cloud Identity Services. Each requires its own user access assignment.

Access assignments are not inherited. If an assistant invokes one or more agents, assigning a user to the assistant does not automatically grant them access to those agents. You must assign the user to the assistant and to each agent it invokes separately. If any assignment is missing, the user receives an authorization error when the assistant attempts to invoke the unassigned agent, even if the user has access to all the other entities.

As an IAM administrator, plan your access assignments across the full chain of entities a user needs to reach, not just the entry point. For more information about how to perform these assignments, see Enable Users to Access Agents [page 2338].

What is an Agent Identity?

An agent identity in SAP Cloud Identity Services consists of the following components:

Application Artifact

- Represents a trusted client or system, such as S/4HANA or a dedicated agent application.
- Includes metadata such as redirect URIs, keys, and trust configuration.
- Establishes the technical connection for the SAP landscape.

Agent User (Technical User)

- Every agent has an associated technical user in the directory. This user is not a human user and can't authenticate through a browser (front channel). It authenticates only through back-channel methods such as client credentials, JWT bearer, and token exchange.
- Agents always act on behalf of a human user. The agent user is used to assign authorization policies and user groups to the agent. These assignments define what the agent can do.
- In a future release, agents will be able to act on their own behalf without a human user context.

Dual Authorization Model

- Agents act on behalf of a human user. For an action to succeed, both the agent and the user must have the necessary authorizations. The agent can access only the APIs defined by its authorization policies. The target application also applies the user's own authorization checks. An action succeeds only when both the agent's scope and the user's permissions allow it.

The system creates or deletes agents automatically when you subscribe or unsubscribe to an application or use an AI tool to create an agent.

Core Use Cases

Agent Acting for Present Human Users

When a human user is present and delegates permissions:

- The human-in-the-loop flow requests user approval.
- The agent requests a user token through the token exchange flow.
- The token includes user context for authorized actions.

> ⓘ Planned
>
> Additional use cases are planned for future releases. These use cases include agents acting on your behalf when you're offline (using stored delegation relationships) and unattended agents acting on their own behalf without you in the loop. These use cases aren't currently supported.

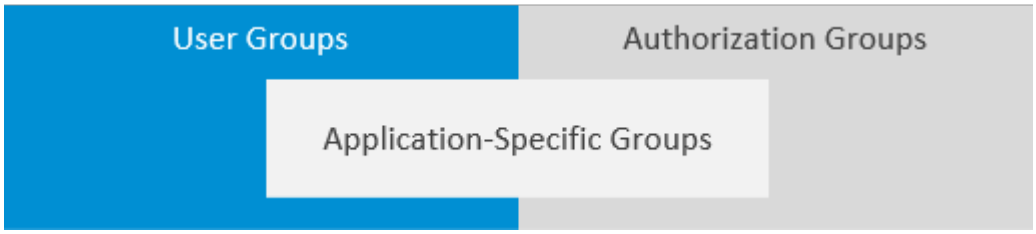
1.3.9 Groups

SAP Cloud Identity Services offers groups to organize users based on common characteristics, authorization, or application. Use them to efficiently manage user access and permissions within your organization's SAP Cloud Identity Services environment.

There are two kinds of groups in SAP Cloud Identity Services - *user groups* and *authorization groups*, and one special group - *application-specific groups*.



The following sections explain the different groups.

User Groups

The user groups serve to create sets of users who have something in common. An example for a user group is a group of users who work in the same department, or users who have similar tasks in a company.

The type of these groups in the administration console for SAP Cloud Identity Services is *User Group*.

For more information, see Managing Groups [page 2393].

Authorization Groups

The authorization groups are related to authorization of users, groups or applications.

The groups that result from the creation of authorization represent the authorization policies that are available in the administration console for SAP Cloud Identity Services. When you create a new authorization, a group with the same name is also created and appears in the list of the groups. Initially, only the authorization groups related to the base authorization policies are visible.

> ⚠ Restriction
>
> You can't modify or delete an authorization group that is related to an authorization policy via the administration console.

The type of these groups in the administration console is *Authorization*

For more information, see Managing Groups [page 2393], Configure Authorizations Based on Policies [page 2311] and Configuring Authorization Policies [page 2244].

Application-Specific Groups

The application-specific groups are a special kind of groups which are bound to an application and can be created in the Identity Directory of SAP Cloud Identity Services or Identity Authentication (SCIM API version 2) target system by running provisioning jobs, or via the administration console. For more information, see Start and Stop Provisioning Jobs [page 2472] and Create a Group [page 2398].

The extension schema of the Identity Directory API *urn:ietf:params:scim:schemas:extension:sap:2.0:Group* defines the following attributes:

- `applicationId` - supported for the Local Identity Directory and Identity Authentication (SCIM API version 2) default write and proxy write transformations as mandatory attribute. The value of this attribute is provided from the source system by setting the property `ips.application.id`. For more information, see List of Properties [page 80] →`ips.application.id`.
- `type` - supported by the Local Identity Directory and Identity Authentication (SCIM API version 2) source, target, and proxy provisioning systems as optional attribute. If no value is specified in the write or proxy write default transformations, the default value `userGroup` is set.
- `supportedOperations` - supported by Local Identity Directory and Identity Authentication (SCIM API version 2) source, target, and proxy provisioning systems as optional attribute. If no value is specified in the write or proxy write default transformations, the default value `readWrite` is set. The attribute defines the supported update options for the application-specific group.
- `externalName` - unique within the application. If this attribute is present, it is sent with the other configured attributes in the OpenID Connect (OIDC) token or SAML 2.0 assertion. The value is immutable.

  > ⓘ Note
  >
  > Two groups with same `externalName` for two different applications can be created, but the same scenario for one application is not allowed.

- `children` - a list of child groups used to represent hierarchical group structures. By default, this attribute is not included in the response when retrieving group data. The `children` attribute is supported only for single group retrieval.

  > **→ Remember**
  >
  > To include the `children` attribute in the response for a single group, you must explicitly request it using the `attributes` query parameter. For example:
  >
  > ```
  > /scim/Groups/{id}?
  > attributes=urn:ietf:params:scim:schemas:extension:sap:2.0:group:children
  > ```

  > **⚠ Restriction**
  >
  > When retrieving multiple groups, the `children` attribute can't be requested. If you attempt to include this attribute in the `attributes` query parameter for multiple groups, the Identity Directory API will return a status code 400, along with a message indicating that requesting the `children` attribute is only supported for single group retrieval.

- `externalLocation` - Specifies the location of the source group. The value is immutable.

  > **ⓘ Note**
  >
  > In the Administration Console you can navigate from the group with `externalLocation` attribute to the same group in the application from which the group comes : *sign in to the administration console* *select the relevant group* *Go to source application*.

The application-specific groups appear with their name in the *Application Name* column in the administration console for SAP Cloud Identity Services under the *Groups* tile. The *Application Name* column for the groups that aren't application-specific is empty.

> **⚠ Restriction**
>
> You must be assigned to a policy that allows reading applications, or to the *Manage Applications* role to view *Application Name* column. For more information, see Configure User Authorizations [page 2312].

The application-specific groups can be of the following types:

Application-Specific Groups Types

Group Type Technical Name	Group Type in Administration Console	Description
`userGroup`	*User Group*	A group of users who have something in common.
`authorization`	*Authorization*	A group related to authorization of users, groups or applications.
`deepLinkActivationPermission`	*Deep Link Activation*	A group of applications that support deep linking.

The application-specific groups support the following operations:

Application-Specific Groups Supported Operations

Supported Operation Technical Name	Supported Operation in Administration Console	You can
`readOnly`	*Read*	• View the group details and group members. • Edit the *Display Name* and *Description* of the group. • Delete the group.
`readWrite`	*Read & Write*	• View the group details and group members. • Edit the *Display Name* and *Description* of the group. • Delete the group. • Add new entities - users, and groups, as group members. • Remove entities - users, and groups, from the group members.
`userOnlyMembership`	*User Membership Only*	• View the group details and group members. • Edit the *Display Name* and *Description* of the group. • Add new entities - users, as group members. • Remove the users from group members.
`membership`	*Membership Only*	• View the group details and group members. • Edit the *Display Name* and *Description* of the group. • Add new entities - users, and groups, as group members. • Remove entities - users, and groups, from the group members.

1.3.10 Authorization Policies

Authorization Management lets administrators control who can access what in business applications.

Authorizations can be functional and instance-based. Administrators refine authorization policies that give access to resources in enabled business applications. They can restrict predefined and custom authorization policies based on user and business object attributes and assign them to users with the group management capabilities of the identity directory. See Configuring Authorization Policies [page 2244].

Prerequisites

In line with SAP's identity and access management (IAM) strategy, an identity directory with user profiles is a prerequisite for using Authorization Management. For more information, see CIO Guide: Identity Lifecycle in SAP Landscapes.

Overview

Authorizations are a critical component of any business domain. For cloud business applications to be enterprise-grade and ready, they must incorporate a robust and highly customizable authorization concept. This involves not only checking permissions for business actions but also ensuring these actions are performed on the correct business objects, known as resources.

Functional Authorizations

Functional authorizations are mandatory because they define what actions a user can perform in an application, such as reading data, creating records, or administrative tasks.

Following the principle of least privilege, each user receives only the permissions required for their work, with separate authorizations for personas such as administrators, support staff, auditors, key users, and specific roles like accountants or production planners. Authorization must be enforced consistently across all access paths, including user interfaces, APIs, batch processes, and search results.

Instance-Based Authorizations

Instance-based authorizations control who can perform specific actions on specific resources. They restrict access to specific data objects within functional authorizations. For example, in a financial application, a user might be authorized to make journal entries, but only within certain company codes. Conversely, the same user might be allowed to execute the closing process at the end of periods for different company codes. This nuanced approach ensures that permissions are tailored to specific business needs and contexts.

Using Authorization Policies in Custom Applications

For developers of SAP BTP based business applications, handling authorizations should be straightforward. The authorization framework enables developers to easily declare and enforce their business-specific authorization models.

There are libraries for developers of SAP BTP based business applications to declare and enforce functional and instance-based authorization. Authorizations are declared as code-based "authorization policies" of the business application and enforced with client libraries for Node.js, Java, and Go, and they provide value help for authorization administration. Authorization Management is fully integrated in the Cloud Application Programming model (Authorization and Access Control) and supports typical SAP BTP developments (Developing Authorizations [page 2876]), such a Cloud Foundry and Kyma.

SAP-Managed SAP Cloud Identity [page 520]

1.3.11 SAP-Managed SAP Cloud Identity

SAP Cloud Identity Services support both SAP-managed and customer-managed integration models, depending on who is responsible for maintaining and operating the tenant, application and provisioning configurations.

Overview

SAP-managed refers to a delivery approach in which SAP is responsible for key technical and operational aspects of the solution. This approach reduces complexity for you and provides a consistent, best-practice experience. SAP manages the software lifecycle, including provisioning, technical integration, monitoring, automatic updates, backups, and offboarding. For more information, see SAP Note 3709792 and SAP's Responsibilities.

> **Note**
>
> To use the SAP-managed delivery approach, your tenant must run on the SAP Cloud Identity Services infrastructure. If your tenant is still running on the Neo environment, you must first migrate it to the SAP Cloud Identity Services infrastructure.
>
> For more information, see Migrate Identity Provisioning Bundle Tenant.

Customer-managed refers to a delivery approach in which you are responsible for configuring and maintaining your tenants according to your business requirements. This approach allows you to adapt features and functionality to your specific needs. For more information, see Your Responsibilities.

SAP-managed SAP Cloud Identity Services support the following delivery approaches: SAP can manage both the tenant and the integrated applications. You can also manage your own tenants, with SAP managing the integrated applications connected to those tenants.

What does SAP-managed mean for the individual services within SAP Cloud Identity Services?

Identity Authentication

- SAP manages the trust between SAP Cloud Identity Services and the connected SAP applications.
- In the SAP Cloud Identity Services administration console, the *Conditional Authentication* and *Authentication and Access* settings for these applications are read-only and can't be modified.
- The *Provisioning* tab, which is used to enable central-store based provisioning, is not available.
- The *Authorization Policies* tab remains available and can be configured as needed.
- Most settings under *Branding and Layout* can be modified, with the exception of *Token URL Separator* and login page behavior, which remain SAP-managed.

Identity Provisioning

- SAP-managed source and target systems are automatically preconfigured and maintained by SAP. As a result, these systems are not displayed in the administration console. You cannot manually schedule or run provisioning jobs for them. Also, you cannot access their job logs.
- Data replication is automated. Provisioning jobs run automatically every 30 minutes.
- You can still create and configure provisioning systems, as well as schedule and run provisioning jobs according to your business requirements.

> ⚠ Caution
>
> Do not create configurations that duplicate or overlap with SAP-managed provisioning flows. This includes configuring jobs and modifying transformations. Running both SAP-managed and customer-managed provisioning for the same back-end systems within the same SAP-managed flow, results in data inconsistencies.

Monitoring and Support

For SAP Cloud Identity Services, you can monitor and troubleshoot the parts you manage. For more information, see Monitoring and Troubleshooting [page 2964].

If you encounter issues, you can report an incident to SAP Support. For information, see Getting Support [page 3141].

SAP-Managed IAM for Joule

> ⚠ Caution
>
> This section is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available outside this program.

SAP-managed IAM for Joule represents an initial step toward the same unified identity model used for the SAP Business Suite. In the Business Suite model, SAP Cloud Identity Services is the authoritative source for user and role data. Assignments are distributed outward to connected applications. The current Joule model adopts a pragmatic starting point: user records and group assignments originate in each line-of-business application. Identity provisioning jobs read this data from the line-of-business system into SAP Cloud Identity Services. The jobs then write the global user ID back to the line-of-business system to link the records. The line-of-business system remains the authoritative source for user and role data in the current release.

This approach enables Joule to reuse existing user and role data without requiring you to restructure your landscapes. Fully centralized assignment management in SAP Cloud Identity Services (the same harmonized model as the Business Suite) is planned for a future release.

For the EAC program, the following restrictions and requirements apply to identity provisioning for SAP-managed Joule, in addition to those described in the *Identity Provisioning* section above:

- You must manually import SAP-managed provisioning job templates from SAP Note 3784171. The system doesn't yet create jobs automatically when you activate Joule for a line-of-business application. (If you are part of the EAC program and need access to this SAP Note, open an incident under BC-IAM-IPS.)

  > ⚠ Caution
  >
  > Do not modify the imported SAP-managed provisioning job templates. If issues occur, do not create duplicate jobs or change the template configurations. Contact SAP Support for assistance.

- You must set up the SAP-managed provisioning jobs after the application representing the line-of-business system already exists in SAP Cloud Identity Services. This ensures that application-specific groups created by the provisioning job are associated with the correct application.
- Before you run the provisioning jobs, every user in scope must have logged in at least once to the line-of-business application using SAP Cloud Identity Services as the identity provider. The system can't automatically consolidate users who haven't signed in yet.
- For SAP S/4HANA Cloud, the communication arrangement for SAP-managed identity provisioning uses communication scenario `SAP_COM_1265`.
- You don't need identity provisioning jobs for SAP LeanIX. The access token issued by LeanIX already contains the required group information.

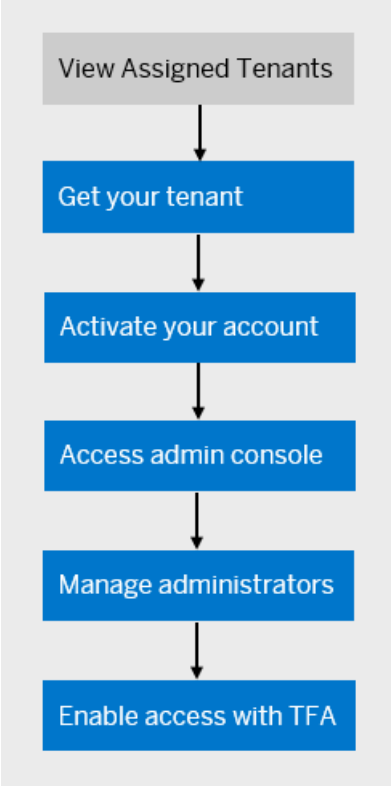
1.4 Initial Setup

The initial setup of SAP Cloud Identity Services involves the following steps:

Quickstart



- [page 523]
- [page 524]
- [page 524]
- [page 524]
- [page 524]
- [page 524]

The tenant administrator performs all the steps in the *Initial Setup* section. Hover over the image and click the highlighted areas for more information on each individual step.

View Assigned Tenants and Admins

Before getting a tenant, check if there is an existing one assigned to your customer ID.

- If there is an existing tenant and you are among its administrators, skip this step and access the administration console [page 542]. Your existing tenant will be reused.
- If there is no existing tenant, follow the steps below.

See View Assigned Tenants and Administrators [page 525]

Get Your Tenant

As a customer, you are entitled to one productive and one test SAP Cloud Identity Services tenant. You are also allowed to request an additional tenant. Trial tenants are open to everyone.

See Get Your Tenant [page 528]

Activate Your Account

Once you get your tenant, you receive an email with instructions to activate your account for the administration console of SAP Cloud Identity Services. This tool is the central point for configuring identity authentication and provisioning scenarios.

See Activate Your Account [page 540]

Access Admin Console

Once you activate your account and sign in successfully, you open the SAP Cloud Identity Services administration console. You are the initial administrator user listed under *Users & Authorizations* > *Administrators*.

See Access Admin Console [page 542]

Manage Administrators

As the initial administrator user of SAP Cloud Identity Services, you can view and manage your predefined authorizations, add new administrators, as well as define authorization policies to further control their data access.

See Manage Administrators [page 543]

Enable Two-Factor Authentication

We recommend that you protect the access to the SAP Cloud Identity Services administration console with two-factor authentication (TFA). Compared to single-factor authentication, two-factor authentication provides enhanced security.

See Enable Two-Factor Authentication [page 544]

1. View Assigned Tenants and Administrators [page 525]
   View all SAP Cloud Identity Services tenants that are assigned to your customer ID with the *iamtenants* application or the Cloud Identity Services Administrators Card on the SAP for Me portal.
2. Get Your Tenant [page 528]
   Get your SAP Cloud Identity Services tenant and become productive.
3. Activate Your Account [page 540]
   Open the email from your SAP team and follow the instructions to activate your account.
4. Access Admin Console [page 542]
   Sign in to the administration console of SAP Cloud Identity Services.

5. Manage Administrators [page 543]
   View and configure the administrator authorizations. Add additional user administrators.
6. Enable Two-Factor Authentication [page 544]
   Enable two-factor authentication for all administrators accessing SAP Cloud Identity Services administration console.

1.4.1 View Assigned Tenants and Administrators

View all SAP Cloud Identity Services tenants that are assigned to your customer ID with the *iamtenants* application or the Cloud Identity Services Administrators Card on the SAP for Me portal.

Prerequisites

You have an *S-user*. For more information, see About the User, Authorization, and Administrator Concept.

Context

The SAP Cloud Identity Services - Tenants application shows which are the Identity Authentication and Identity Provisioning tenants that are assigned to a customer ID and who are the tenant administrators of these tenants. The information also includes the status of the administrator. Only administrators that have the *Manage Tenant Configuration* role are displayed.

The default tenants, one test and productive tenant per customer, are provided regardless of the number of contracts signed in which SAP Cloud Identity Services is included or bundled. Additional productive or test tenants beyond the initial ones must be purchased separately. For more information, see Tenants [page 27].

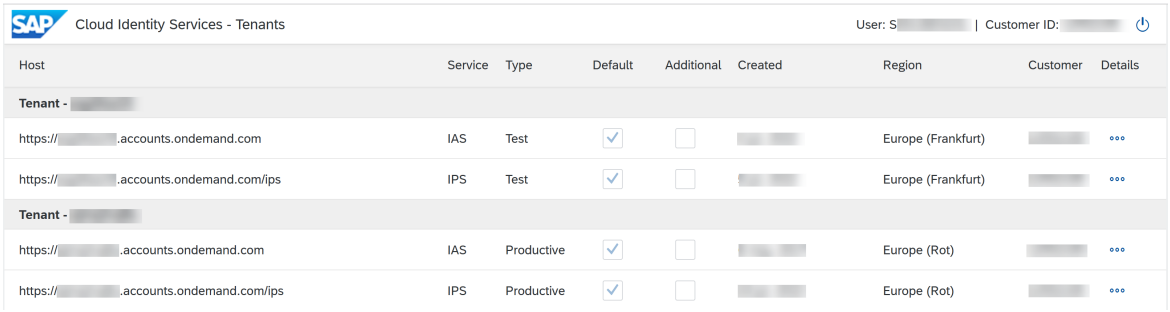
> → Tip
>
> As an alternative, you can view the tenant administrators of the tenants that are assigned to you and add new administrators in SAP Cloud Identity Services via the SAP for Me portal. For more information see Cloud Identity Services Administrators Card.

Procedure

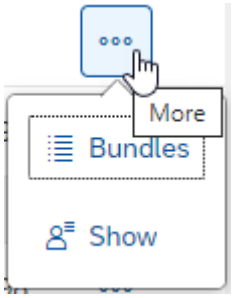
1. Access the SAP Cloud Identity Services - Tenants application via the following URL:https://iamtenants.accounts.cloud.sap/
2. Sign in with your *S-user*.

   > ⚠ Restriction
   >
   > Not signing in with an *S-user* returns *HTTP Status 500 - Internal Server Error*.

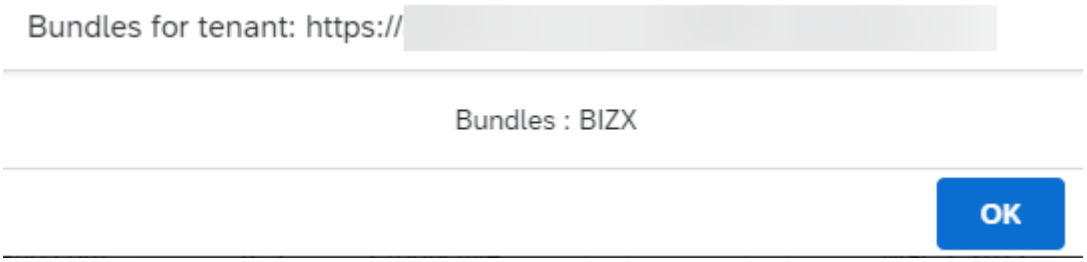
You can view the Identity Authentication and Identity Provisioning tenants that are assigned to your customer ID.



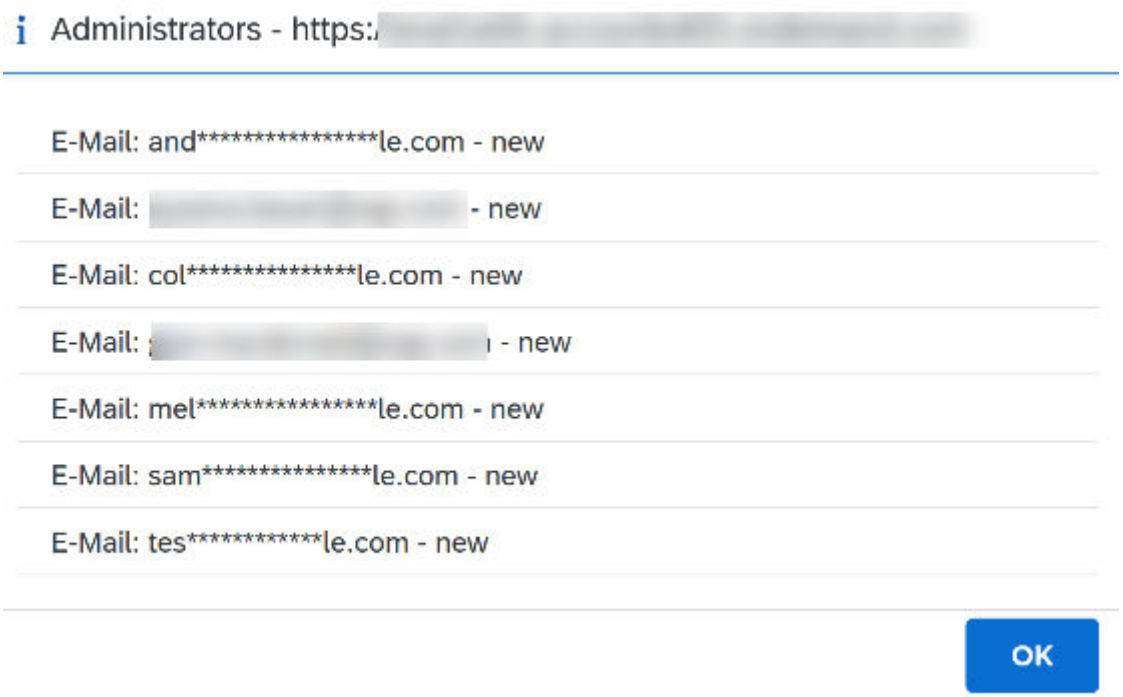
3. Choose details next to the tenant to view the bundles or tenant administrators for that tenant.



- Bundles - shows the bundles for the tenant.



- Show - shows the administrators for the tenant.



> **Note**
>
> The users and emails are masked if the domain of the authenticated user is different from the domain of the tenant administrators.

Task overview: Initial Setup [page 523]

Next: Get Your Tenant [page 528]

Related Information

Tenants [page 27]

1.4.2 Get Your Tenant

Get your SAP Cloud Identity Services tenant and become productive.

Check Your Tenant Availability

Check whether you already have an assigned SAP Cloud Identity Services tenant or need to request one. Use one of the following tools to check your tenant availability:

- SAP Cloud Identity Services - Tenants (*iamtenants*) application:
  Go to https://iamtenants.accounts.cloud.sap/. For more information, see Viewing Assigned Tenants and Administrators.
- SAP for Me:
  Check the Public Cloud Systems card. For more information, see Public Cloud Systems Card.

Based on the result:

- If a tenant exists and you are one of its administrators, go to Access Admin Console [page 542].
- If no tenant exists, follow the steps below to request one according to your needs.

You receive an SAP Cloud Identity Services tenant either as part of a bundle with an SAP cloud solution or through a self-service request in SAP for Me or SAP BTP cockpit.

Bundle with an SAP Cloud Solution

When you purchase an SAP cloud solution that bundles with SAP Cloud Identity Services, you are entitled to one productive and one test tenant. Depending on the specific cloud solution, SAP may provision only one productive tenant, only one test tenant, or both.

If you already have a tenant and purchase additional SAP cloud solutions, you will not get additional tenants. Your existing one will be reused. However, there are some special cases and exceptions to this rule. For example:

- Your business operates in multiple regions, and your SAP cloud solutions are delivered across these regions. You can request additional SAP Cloud Identity Services tenants in the particular region where other SAP cloud solutions have been licensed.
- You have multiple instances of SAP SuccessFactors. It is not recommended to bundle them with the same SAP Cloud Identity Services tenant. Instead, you can request a dedicated tenant for each SAP SuccessFactors instance through the SAP SuccessFactors Upgrade Center.

> → Recommendation
>
> Using a single productive SAP Cloud Identity Services tenant for your SAP cloud solutions is important for the integration and out-of-the-box Single Sign-On (SSO) between these solutions. If your company is already using a productive SAP Cloud Identity Services tenant, we strongly recommend reusing it for any additional SAP cloud solutions you plan to purchase and adopt.

Getting a bundled tenant is generally an automatic process that requires no customer interaction. SAP takes care of creating and provisioning the tenant based on your cloud solution and regional choices. If you don't have a tenant, a new one will be created. If you have multiple tenants, the default tenant—typically the first one created for you—is selected and provisioned with the cloud solution. This automatic process is also used to create additional tenants when it is necessary to comply with specific regulations and in scenarios involving SAP SuccessFactors.

There are cases where customer interaction is required. If multiple tenants are available for selection, for example when using SAP for Me, Boosters, SAP SuccessFactors Upgrade Center, or other tools, you will need to choose the most appropriate one.

> → Tip
>
> If you have multiple SAP Cloud Identity Services tenants and are unsure which one to select, consider these recommendations:
>
> - Default Tenant: A tenant marked as `Default` is typically the first one created for the customer. Many SAP applications automatically integrate with this tenant when provisioned. Choose it if these specifics matter to you. To check which tenant is your default one, refer to View Assigned Tenants and Administrators [page 525].
> - Regional Provisioning: For customers with an `EU Access` contract, choose an SAP Cloud Identity Services tenant located in Europe if your SAP cloud solution is provisioned in an `EU Access` region. This ensures better performance and compliance with the European regulations. For more information, see EU Access.
> - Multi-Regional Requirements: If your business operates in multiple regions and needs additional tenants, you can request them by following the process described in Get Additional Tenant [page 533]. Keep in mind that having a dedicated tenant per region might mean SSO isn't guaranteed out-of-the-box.
> - SAP SuccessFactors Use Case: If you have multiple instances of SAP SuccessFactors, you can request a separate SAP Cloud Identity Services tenant for each instance from the SAP SuccessFactors Upgrade Center. This ensures that each instance, representing the system of origin for employees, will have a dedicated identity provider and proper handling of users with the same login name. For more information, see Initiating the Upgrade to SAP Cloud Identity Services - Identity Authentication Service.

When tenants delivered as part of the bundling process are created, you get their tenant URLs in a welcome email from SAP. For more information, see Bundles [page 35].

Self-Service Request in SAP for Me

To request a tenant of SAP Cloud Identity Services, you can use SAP for Me, the SAP's central customer portal for managing products, systems, and entitlements.

In SAP for Me, there are two starting points for tenant provisioning: Portfolio & Products and Systems & Provisioning. Portfolio & Products serves as the commercial catalog and shows what you purchased, such as entitlements, licenses, and product roadmaps. Systems & Provisioning is the area where you view, request, activate, and manage your cloud tenants.

Get Tenant in SAP for Me (Portfolio & Products)

Use this option to request a test or production tenant of SAP Cloud Identity Services for integration with SAP-managed cloud ERP applications, Joule, and other supported solutions. The tenant is provisioned in your selected region and comes with SAP-managed integration configurations.

For more information, see Provisioning and Identity and Access Management in SAP Managed Cloud ERP Applications.

> ### Note
>
> New tenants are created only if there are no existing tenants bound to the customer ID.

1. Log on to SAP for Me with your S-user ID and password and open the Portfolio & Products dashboard.
2. Go to the *My Product Packages* tab.
3. Select the *SAP Cloud Identity Services* tile.
4. Go to the *Applications* tab.
5. In the *SAP Cloud Identity Services* tile, choose *Start Provisioning*.
   The *Create Solution* wizard is launched.
6. In the *General Information* section, provide the following data for the solution:
   - *Entitlement System*: Displays the system ID of SAP Cloud Identity.
   - *Name*: **<Name>**

     > ### Caution
     >
     > You can't rename solutions after you create them.

     > ### Note
     >
     > Names must meet these guidelines:
     >
     > - Limit names to 63 characters.
     > - Use only lowercase letters (a-z), numbers (0-9), hyphens (-), and periods (.).
     > - Start and end with a letter or number.
     > - Use a name that's unique within the selected resource group.

   - *Path*: Use the *Value Help* ( ) to select a path to a resource group.
   - *Business Type*: Select *Test* or *Production* from the dropdown menu.

   Choose *Next Step*.
7. In the *Configure Parameters* section, select a region. Choose *Review*.
8. Review your entries and choose *Finish*.
   Your provisioning request for the solution has started and its resources are being set up in the selected resource group. The provisioning process can take a few moments to complete.
   The new solution resource will achieve the ready status when all tenants are successfully provisioned and integrations are fully established. To view the status of the generated resources, go to the *Resources* tab.

After the SAP Cloud Identity tenant is provisioned, you can proceed with provisioning your SAP cloud applications. During this process, the newly provisioned SAP Cloud Identity tenant, associated with the application tenant, will be available for selection.

Get Tenant in SAP for Me (Systems & Provisioning)

Use this option to request a test or production tenant of SAP Cloud Identity Services bundled with an SAP cloud solution. The tenant is provisioned in the same region as the bundled solution and preconfigured accordingly.

There is no explicit option to request a tenant as part of this provisioning flow. When you provision your application, and no SAP Cloud Identity Services tenant is available for selection, a tenant is automatically created when you submit the provisioning request.

In some situations, automatic tenant creation is not available. In these cases, you must first request a tenant manually in the SAP BTP cockpit, as described in the *Self-Service Request in SAP BTP Cockpit* section below. After the tenant is created, return to SAP for Me and restart the provisioning process so the new tenant becomes available for selection. You can recognize this situation when the *Start Provisioning* button (step 3 below) is disabled.

1. Log on to SAP for Me with your S-user ID and password and open the Systems & Provisioning dashboard.
2. Go to the *Provisioning* tab.
3. Under *Systems to be Provisioned*, choose *Start Provisioning* for the SAP cloud solution you want to bundle with SAP Cloud Identity Services.
4. In the *Start New Provisioning Request* dialog, provide the following information:
    1. *Region*: The geographic location of the data center where the SAP cloud solution tenant will be deployed.
    This option is not available for all applications. In some cases, the region may be system-determined based on the contract.
    2. *Integration with SAP Cloud Identity Services*: Select either a test or production SAP Cloud Identity tenant.
    By default, you can select either a productive or a test SAP Cloud Identity tenant, depending on the type of application tenant being provisioned. For some applications, you may also have the option to integrate a test application tenant with a productive SAP Cloud Identity tenant.
    For more information, see Onboard to SAP Cloud Identity Services.
    3. *Owner of SAP Cloud Identity Services*: Choose one of the following:
    Own systems – SAP Cloud Identity tenants that belong to the same Customer ID as the SAP cloud solution being provisioned.
    Shared systems – SAP Cloud Identity tenants that belong to a different Customer ID but are shared with your company.
    For more information, see KBA 2632518 and Reuse SAP Cloud Identity Services Tenants for Different Customer IDs.
5. Choose *Submit*.

For more information on getting started and the SAP for Me dashboards, see SAP for Me Online Help.

Self-Service Request in SAP BTP Cockpit

Products delivered on SAP Business Technology Platform (SAP BTP) do not trigger automatic creation of SAP Cloud Identity Services productive and test tenant. You need to request the tenant in the SAP BTP cockpit.

This is true in most cases, but not for all SAP BTP applications, and depends on the subaccount where the application runs on. In SAP BTP, there are customer-managed and SAP-managed subaccounts.

- If the application runs on SAP-managed subaccount, then the SAP Cloud Identity Services tenant is automatically provisioned with the application. In this case, the administrator of the customer doesn't have access to the SAP BTP subaccount.
- If the application runs on customer-managed subaccount, then in most cases the administrator of the customer has to manually create SAP Cloud Identity Services tenant via SAP BTP cockpit. However, there are also exceptions, like SAP Cloud ALM (application lifecycle management), where SAP creates and provisions the SAP Cloud Identity Services tenant.

Additional tenants and trial tenants are also created through self-service request.

Get Productive and Test Tenant

Get your productive and test tenant as part of a self-service request in SAP BTP cockpit. Productive and test tenants have no difference from technical and functional perspective.

Prerequisites

- You have a global account in SAP BTP cockpit with a multi-environment subaccount.

Procedure

1. Access the SAP BTP cockpit, choose your subaccount and navigate to it by choosing its tile.
2. In the navigation area, choose *Entitlements*. You have two options:
   - if you see *default (Application)* for Cloud Identity Services in the entitlements page of your subaccount, skip steps 4 to 6, and go to step 7.
   - if you don't see *default (Application)* for Cloud Identity Services in the entitlements page of your subaccount, continue with step 4.

   > → Tip
   >
   > - If you use directories entitlement management in your global account, you must assign the *default (Application)* plan to the directory first, and after that to the subaccount. Once you assign the *default* plan to your directory, it will appear in your subaccount entitlements too. For more information, see Configure Entitlements and Quotas for Directories.

3. Choose *Edit* > *Add Service Plans*, and select *Cloud Identity Services* from the list of entitlements available for this subaccount.
4. Mark the *default (Application)* plan. The *0* number in the *Add 0 Service Plan* button increments to *1*.
5. Choose the *Add 1 Service Plan* button.
6. Save your changes on the *Entitlements* page.
7. Navigate to *Services* > *Service Marketplace* and select the *Cloud Identity Services* tile. Under *Application Plans* you should see the *default* plan.
8. In the top-right corner, choose *Create* and follow the steps in the wizard to configure your new Cloud Identity Services tenant:
   1. From the dropdown list, choose *Cloud Identity Services*.
   2. Select the *default* plan and then choose *Next*.
   3. From the *Cloud Service Type* dropdown, choose the tenant type: *TEST* or *PRODUCTIVE* (default value).

4. Choose *Next*, review your configuration and choose *Create*.

> **Note**
>
> For each service plan you must have a separate subaccount.
>
> The default plan allows you to consume SAP Cloud Identity Services. New tenants are created only if there aren't already existing tenants of the same type (productive or test) bound to your customer ID, regardless of the region.
>
> The default test and productive tenants will be created in the same region.

9. If you initially create a test tenant and then you want to proceed with a productive one (or vice versa), repeat the preceding steps in a separate subaccount of the same region.

Next Steps

Go to your email inbox and activate your account. For more information, see Activate Your Account [page 540].

> **Note**
>
> **SAP BTP, Neo subaccount**
>
> If you have a global account with Neo subaccount, you can get a productive tenant and use it for free under the General Terms and Conditions for SAP Cloud Services. For this, you need to open your Neo subaccount, navigate to *Services* > *Identity Authentication* tile and enable the service. The new tenants are created only if there aren't existing productive tenants bound to your customer ID already.

Get Additional Tenant

Get an additional tenant as part of a self-service request in SAP BTP cockpit. SAP customers and partners can use SAP Cloud Identity Services additional tenants via CPEA (Cloud Platform Enterprise Agreement) and Pay-As-You-Go consumption-based commercial models. They can request one additional tenant per SAP BTP subaccount.

> **Note**
>
> The additional tenant doesn't add additional logon requests. Licensed logon requests are distributed across all tenants.

Prerequisites

- You have a global account in SAP BTP cockpit with a multi-environment subaccount.
- You have an existing default tenant. A tenant marked as default is typically the first one created for the customer. Many SAP applications automatically integrate with this tenant when provisioned. To check which tenant is your default one, refer to View Assigned Tenants and Administrators [page 525].

Procedure

To get additional tenant using SAP BTP multi-environment subaccount, proceed as follows:

1. Access the SAP BTP cockpit, choose your subaccount and navigate to it by choosing its tile.
2. In the navigation area, choose *Entitlements*. You have two options:
   - if you see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, skip steps 3 to 6, and go to step 7.
   - if you don't see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, continue with step 3.

   → Tip

   - If you use directories entitlement management in your global account, you must assign the *additional-tenant (Application)* plan to the directory first, and after that to the subaccount. Once you assign the *additional-tenant* plan to your directory, it will appear in your subaccount entitlements too. For more information, see Configure Entitlements and Quotas for Directories.
3. Choose *Edit* > *Add Service Plans*, and select *Cloud Identity Services* from the list of entitlements available for this subaccount.
4. Mark the *additional-tenant (Application)* plan. The *0* number in the *Add 0 Service Plan* button increments to *1*.
5. Choose the *Add 1 Service Plan* button.
6. Save your changes on the *Entitlements* page.
7. Navigate to *Services* > *Service Marketplace* and select the *Cloud Identity Services* tile. Under *Application Plans* you should see the *additional-tenant (Application)* plan.
8. In the top-right corner, choose *Create* and follow the steps in the wizard to configure your new Cloud Identity Services tenant:
   1. From the dropdown list, choose *Cloud Identity Services*.
   2. Select the *additional-tenant* plan and then choose *Next*.
   3. From the *Cloud Service Type* dropdown, choose the tenant type: *TEST* or *PRODUCTIVE* (default value).
   4. Choose *Next*, review your configuration and choose *Create*.

   ⓘ Note

   For each service plan you must have a separate subaccount.

   The *additional-tenant* plan allows the customer to create a new SAP Cloud Identity Services additional tenant. The type of the created tenant may be test or productive depending on the customer selection. The new instance is created only if there is an existing default instance bound to your customer ID.

   You can delete the additional tenant by choosing the *Delete* button, which initiates the deletion of the subscription to the additional-tenant plan of Cloud Identity Services in your subaccount. The tenant will be deactivated for 30 days before being permanently deleted. After deletion, it cannot be restored.

Next Steps

Go to your email inbox and activate your account. For more information, see .Activate Your Account [page 540]

ⓘ Note

SAP BTP, Neo subaccount

If you have a global account with an SAP BTP, Neo subaccount, you can get an additional tenant, too.

Open your existing CPEA Neo account or create new CPEA Neo account, navigate to *Services* > *Identity Authentication - Additional Tenant* tile and enable the service.

Identity Authentication additional productive tenant will be created and the account member who triggered the creation will get an activation email. Note that test tenants cannot be created from a Neo subaccount.

You can delete the additional tenant by choosing the *Delete* button, which initiates the deletion of the subscription to the additional-tenant plan of Cloud Identity Services in your subaccount. The tenant will be deactivated for 30 days before being permanently deleted. After deletion, it cannot be restored.

Migrate Additional Tenant from Neo to Multi-Environment

Migrate an additional tenant from a Neo Subaccount to a multi-environment subaccount as part of a self-service request in SAP BTP cockpit.

→ Remember

SAP Business Technology Platform, Neo environment will sunset on **December 31, 2028**, subject to terms of customer or partner contracts.

For more information, see SAP Note 3351844.

⚠ Caution

The SAP NetWeaver AS JAVA user store scenario is only supported in the Neo environment. For more information, see Corporate User Store (Neo Environment) [page 2531].

Prerequisites

- You have a global account in SAP BTP cockpit with a multi-environment subaccount.
- You have an existing additional tenant on SAP BTP, Neo subaccount.

ⓘ Note

The additional tenant doesn't add additional logon requests. Licensed logon requests are distributed across all tenants.

Procedure

To migrate an additional tenant from a Neo subaccount to a multi-environment subaccount, proceed as follows:

1. Access the SAP BTP cockpit, choose your multi-environment subaccount and navigate to it by choosing its tile.
2. In the navigation area, choose *Entitlements*. You have two options:
   - If you see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, skip steps 3 to 6, and go to step 7.
   - If you don't see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, continue with step 3.

→ Tip

- If you use directories entitlement management in your global account, you must assign the *additional-tenant (Application)* plan to the directory first, and after that to the subaccount. Once you assign the *additional-tenant* plan to your directory, it will appear in your subaccount entitlements too. For more information, see Configure Entitlements and Quotas for Directories.

3. Choose *Edit* > *Add Service Plans*, and select *Cloud Identity Services* from the list of entitlements available for this subaccount.
4. Mark the *additional-tenant (Application)* plan. The *0* number in the *Add 0 Service Plan* button increments to *1*.
5. Choose the *Add 1 Service Plan* button.
6. Save your changes on the *Entitlements* page.
7. Navigate to *Services* > *Service Marketplace* and select the *Cloud Identity Services* tile. Under *Application Plans* you should see the *additional-tenant (Application)* plan.
8. In the top-right corner, choose *Create* and follow the steps in the wizard to configure your new Cloud Identity Services tenant:
    1. From the dropdown list, choose *Cloud Identity Services*.
    2. Select the *additional-tenant* plan and then choose *Next*.
    3. Under the *Form* tab, from the *Cloud Service Type* dropdown, choose the tenant type: *TEST* or *PRODUCTIVE* (default value).
    4. Under the *JSON* tab, select an already prepared JSON file or specify the parameters in the following JSON format:

        {·} Sample Code

        ```
        {
            "cloud_service": "<the tenant type, TEST or PRODUCTIVE as selected
        in the previous step>",
            "tenant_id": "<the ID of the tenant that will be migrated>",
            "subaccount": "<the ID of the Neo subaccount>"
        }
        ```

    5. Choose *Next*, review your configuration, and choose *Create*.

Next Steps

If the migration is successful, delete the additional-tenant plan from the Neo subaccount. Go to your Neo subaccount, navigate to *Services* > *Instances and Subscriptions* > *Acctions (...)* > *Delete*.

Migrate Additional Tenant from Multi-Environment to Multi-Environment

Migrate an additional tenant from a multi-environment subaccount to another multi-environment subaccount as part of a self-service request in SAP BTP cockpit.

⚠ Caution

The SAP NetWeaver AS JAVA user store store scenario is only supported in the Neo environment. For more information, see Corporate User Store (Neo Environment) [page 2531].

Prerequisites

- You have a global account in SAP BTP cockpit with a multi-environment subaccount.
- You have an existing additional tenant on a multi-environment subaccount.
- The source and target subaccounts must be in the same SAP Cloud Identity Services region.

> **Note**
>
> The additional tenant doesn't add additional logon requests. Licensed logon requests are distributed across all tenants.

> **Note**
>
> The target global account can be different from the source global account, as long as it belongs to the same customer ID.

Procedure

To migrate an additional tenant from a multi-environment subaccount to another multi-environment subaccount, proceed as follows:

1. Access the SAP BTP cockpit, choose your target multi-environment subaccount and navigate to it by choosing its tile.
2. In the navigation area, choose *Entitlements*. You have two options:
   - If you see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, skip steps 3 to 6, and go to step 7.
   - If you don't see *additional-tenant (Application)* for Cloud Identity Services in the entitlements page of your subaccount, continue with step 3.

   > **→ Tip**
   >
   > - If you use directories entitlement management in your global account, you must assign the *additional-tenant (Application)* plan to the directory first, and after that to the subaccount. Once you assign the *additional-tenant* plan to your directory, it will appear in your subaccount entitlements too. For more information, see Configure Entitlements and Quotas for Directories.

3. Choose *Edit* > *Add Service Plans*, and select *Cloud Identity Services* from the list of entitlements available for this subaccount.
4. Mark the *additional-tenant (Application)* plan. The *0* number in the *Add 0 Service Plan* button increments to *1*.
5. Choose the *Add 1 Service Plan* button.
6. Save your changes on the *Entitlements* page.
7. Navigate to *Services* > *Service Marketplace* and select the *Cloud Identity Services* tile. Under *Application Plans* you should see the *additional-tenant (Application)* plan.
8. In the top-right corner, choose *Create* and follow the steps in the wizard to configure your new Cloud Identity Services tenant:
   1. From the dropdown list, choose *Cloud Identity Services*.
   2. Select the *additional-tenant* plan and then choose *Next*.
   3. Under the *Form* tab, from the *Cloud Service Type* dropdown, choose the tenant type: *TEST* or *PRODUCTIVE* (default value).

4. Under the *JSON* tab, select an already prepared JSON file or specify the parameters in the following JSON format:

   Sample Code

   ```
   {
       "cloud_service": "<the tenant type, TEST or PRODUCTIVE as selected
   in the previous step>",
       "tenant_id": "<the ID of the tenant that will be migrated>",
       "subaccount": "<the ID of the source multi-environment subaccount>"
   }
   ```

5. Choose *Next*, review your configuration, and choose *Create*.

Next Steps

If the migration is successful, delete the additional-tenant plan from the source multi-environment subaccount. Go to your source subaccount, navigate to *Services* > *Instances and Subscriptions* > *Acctions (...)* > *Delete*.

Get Trial Tenant

Create a trial tenant from an SAP BTP trial account.

A trial tenant is intended for testing purposes. It allows you to try out and explore SAP Cloud Identity Services – Identity Authentication and Identity Provisioning. It is free of charge and limited to a trial period in accordance with the SAP BTP trial terms and conditions. A trial tenant differs from a test tenant. Trial tenants can be used for a limited period, while test tenants are provided to customers in addition to their productive tenants where they can test new features before implementing them productively.

Restriction

- You can have only one SAP Cloud Identity Services trial tenant per SAP BTP global account regardless of how many subaccounts you create. If you have multiple subaccounts, and you have trial tenants for them, they use one and the same trial tenant.
- You can have up to 50 users in a trial tenant.
- You can't connect to on-premise systems using the cloud connector. It's not possible to subscribe to the cloud Identity Services connectivity plan in your trial subaccount.
- The `Invitation Rest API` is not available. For more information about the API, see Invitation REST API [page 2802].
- Email template customization is not possible.

Prerequisites

- You have a free account on SAP BTP Trial, as described in Get a Free Account on SAP BTP Trial

Procedure

1. Go to the SAP BTP Trial page and click *Log On*.
2. Choose *Go to Your Trial Account* and open your subaccount.

3. In the navigation area, choose *Entitlements*. You have two options:
   - if you see *default (Application)* for Cloud Identity Services in the entitlements page of your subaccount, skip steps 4 to 7, and go to step 8.
   - if you don't see *default (Application)* for Cloud Identity Services in the entitlements page of your subaccount, continue with step 4.
4. Choose *Edit* > *Add Service Plans*, and select *Cloud Identity Services* from the list of entitlements available for this subaccount.
5. Mark the *default (Application)* plan. The *0* number in the *Add 0 Service Plan* button increments to *1*.
6. Choose the *Add 1 Service Plan* button.
7. Choose *Save*.
8. In the navigation area, choose *Services* > *Instances and Subscriptions*.
9. In the top-right corner, choose *Create*, and follow the steps in the wizard to configure your new Cloud Identity Services tenant:
   1. Choose *Cloud Identity Services*.
   2. Select the *default* plan.
   3. Choose *Create*.

Next Steps

Activate your account for Cloud Identity Services.

1. Go to your inbox and open the account activation email.
2. Click the tenant URL provided in the email.
3. Enter a password and choose *Continue*.
   You are informed that your account is successfully activated.
4. Choose *Continue*.
   This opens the administration console of SAP Cloud Identity Services.

> ### Note
>
> You can delete your trial tenant by deleting the subaccount or by deleting the Cloud Identity Services application under the Subscriptions section. For more information, see Delete a Subaccount.

> ### Note
>
> If you encounter any issues and you need support, send an email to `SAPCPTrialSupport@sap.com` or start a discussion in SAP Community.

Assign Existing Tenant to SAP BTP Subaccount

Assign your existing tenant to SAP BTP subaccount.

You can assign existing tenant to an SAP BTP subaccount via the default plan. Activating the default plan does not trigger the creation of new tenants if tenant with the same type already exists.

Prerequisites

- You have an existing tenant delivered as part of a bundle with another SAP product.
- You have a global account in SAP BTP cockpit with a Cloud Foundry subaccount.

Procedure

1. In the SAP BTP cockpit, choose your subaccount and navigate to *Services* > *Service Marketplace*.
2. Select the *Cloud Identity Services* tile. Under *Application Plans* you should see the default plan.
3. In the top-right corner, choose *Create* and follow the steps in the wizard to configure your new instance:
    1. From the dropdown list, choose *Cloud Identity Services*.
    2. Select the *default* plan and then choose *Next*.
    3. From the *Cloud Service Type* dropdown, choose the tenant type: *Test* or *Productive* (default value).
    4. Choose *Next*, review your configuration and choose *Create*.

> ### Note
>
> Although bundled and self-requested tenants differ in the way you get them, from technical and functional perspective they have no differences.

> ### Note
>
> It will take some time until the tenant becomes accessible. If you try to access the tenant right after creating it, you will receive `Error 404 Not Found`.

For more information, see Tenants [page 27].

Parent topic: Initial Setup [page 523]

Previous task: View Assigned Tenants and Administrators [page 525]

Next: Activate Your Account [page 540]

1.4.3 Activate Your Account

Open the email from your SAP team and follow the instructions to activate your account.

The first person who gets an account activation email for the administration console of SAP Cloud Identity Services is the initial admin user.

- If your tenant is obtained as part of a bundle with an SAP cloud solution, **the technical contact person** (also known as Contact Person IT) of the customer receives an email with the tenant URL. He or she is granted the administrator permissions of the tenant and performs the initial logon.

In addition, the technical contact person receives an email from the team of the bundled SAP cloud solution. It contains the tenant URL of the cloud solution and may contain the tenant URL of SAP Cloud Identity Services.

> **Note**
>
> When a customer with existing SAP Cloud Identity Services tenant purchases more bundled SAP cloud solutions, no new tenants are created and the existing one is reused.
>
> - If the contact person of the customer has a user account in this existing tenant, no account activation email is sent. This person can access the SAP Cloud Identity Services - Tenants application at the following URL: https://iamtenants.accounts.cloud.sap/ and check the customer tenants and administrators.
> - If the contact person of the customer has no user account in this existing tenant, and such an account is needed by the solution (application), he or she is created as a regular user and receives an account activation email for the user profile. This user doesn't get access to the admin console unless an administrator grants him or her the necessary permissions.

- If your tenant is obtained as part of the self-service request, **the logged-in user in SAP BTP cockpit** is granted the administrator permissions of the tenant. He or she receives the account activation email and performs the initial logon.

  > **Note**
  >
  > When a customer with existing SAP Cloud Identity Services tenant subscribes to the Cloud Identity Services default plan in SAP BTP cockpit, no new tenant is created and the existing one is reused. The logged-in user doesn't receive an email notification.

1. Click the tenant URL provided in the email.
2. Enter a password and choose *Continue*.
   You are informed that your account is successfully activated.
3. Choose *Continue*.
   This opens the administration console of SAP Cloud Identity Services.
   For regular users, this opens the User Profile page of SAP Cloud Identity Services

Parent topic: Initial Setup [page 523]

Previous: Get Your Tenant [page 528]

Next task: Access Admin Console [page 542]

1.4.4 Access Admin Console

Sign in to the administration console of SAP Cloud Identity Services.

Prerequisites

You have activated your account for the administration console of SAP Cloud Identity Services.

Procedure

1. Open the SAP Cloud Identity Services tenant URL.

   > **Note**
   >
   > The URL has the following pattern:
   >
   > `https://<tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin`
   >
   > *Tenant ID* is an automatically generated ID by the system.
   >
   > If you have a configured custom domain, the URL has the `<your custom domain>/admin` pattern.

2. Sign in to the administration console of SAP Cloud Identity Services.

   The login credentials are set when the administrator logs in for the first time.

   > **Note**
   >
   > If you experience troubles in accessing your tenant, check the Accessing the Administration Console [page 3024] troubleshooting page or report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

Task overview: Initial Setup [page 523]

Previous: Activate Your Account [page 540]

Next task: Manage Administrators [page 543]

1.4.5 Manage Administrators

View and configure the administrator authorizations. Add additional user administrators.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services.
2. Navigate to *Users & Authorizations* > *Administrators* and select your user.
3. Under *Configure Authorizations* view your predefined authorizations and manage them according to your needs.

   For more information, see List Administrators [page 2302] and Edit Administrator Authorizations [page 2309].
4. **Required:** Create additional user administrators.

   > **Note**
   >
   > When the SAP Cloud Identity Services tenant is initially provisioned to your organization, only one user is added as a tenant administrator. After that, due to possible legal and security issues, SAP adds additional tenant administrators only in exceptional cases (for example, the existing administrator left the company, or for some reason there is no active administrator for this tenant). To avoid access related issues in such cases, it is always a good practice for you to assign more than one administrators. Adding additional ones is exclusively in the responsibility of the current tenant administrators.

   For more information, see Add User as Administrator [page 2304]
5. **Optional:** Manage the predefined authorizations of the additional administrators.

   For more information, see Edit Administrator Authorizations [page 2309]
6. **Optional:** Define authorization policies to further control what data administrators can access.

   For more information, see Configure Authorizations Based on Policies [page 2311]
7. **Optional:** Create system administrators.

   For more information, see Add System as Administrator [page 2305]

Task overview: Initial Setup [page 523]

Previous task: Access Admin Console [page 542]

Next task: Enable Two-Factor Authentication [page 544]

1.4.6 Enable Two-Factor Authentication

Enable two-factor authentication for all administrators accessing SAP Cloud Identity Services administration console.

Context

We recommend that you protect the access to the administration console with two-factor authentication (TFA). Requesting additional means of identity verification provides enhanced security.

The initial administrator configures the access to this application under *Applications & Resources* > *Applications* > *System Applications* > *Administration Console* > *Authentication and Access*, where the TFA method must be defined as a default authentication rule under *Risk-Based Authentication*.

For more information, see Configure Risk-Based Authentication for an Application [page 2007].

Previous task: Manage Administrators [page 543]

1.5 Scenarios

Define your user engagement scenario - whether business-to-consumer, business-to-business, or business-to-employee - and explore onboarding and provisioning scenarios for secure authentication and identity management with SAP Cloud Identity Services.

User Engagement Scenarios [page 545]
Identify your relevant user engagement scenario supported by Identity Authentication: consumer (business-to-consumer scenario), partner (business-to-business scenario), and employee (business-to-employee scenario).

Onboarding and Provisioning [page 552]
Onboard your users and groups into the Identity Directory to enable SAP Cloud Identity Services for secure authentication, authorization, and identity lifecycle management.

Identity and Access Management for Joule [page 580]
Identity and access management architecture required for Joule, including the requirement for a single SAP Cloud Identity Services tenant, SAP-managed provisioning, and global user ID assignment. Understand this foundation before you implement Joule to ensure consistent authentication and authorization across all connected SAP applications.

1.5.1 User Engagement Scenarios

Identify your relevant user engagement scenario supported by Identity Authentication: consumer (business-to-consumer scenario), partner (business-to-business scenario), and employee (business-to-employee scenario).

Business-to-Consumer [page 545]
: The business-to-consumer scenario is related to any actions performed by the consumer, such as registration to applications and consumer retailing. In this scenario, administrators facilitate the consumer processes, but they do not act on the consumer's behalf.

Business-to-Business [page 548]
: The business-to-business scenario is related to services for business partners. Unlike the business-to-consumer scenario, consumer self-registration is not allowed, and the administrator of the company is usually the one that triggers the user registration process.

Business-to-Employee [page 550]
: The business-to-employee scenario is related to services for employees of an organization. Employees can access various applications with one logon. Furthermore, administrators can upload employees data by using the user import functionality.

Parent topic: Scenarios [page 544]

Related Information

Onboarding and Provisioning [page 552]
Identity and Access Management for Joule [page 580]

1.5.1.1 Business-to-Consumer

The business-to-consumer scenario is related to any actions performed by the consumer, such as registration to applications and consumer retailing. In this scenario, administrators facilitate the consumer processes, but they do not act on the consumer's behalf.

This scenario includes the following features:

- Authentication with user name and password
- A secure single sign-on to cloud applications
- Social sign-on to cloud applications

  > ⓘ Note
  >
  > The content in this section is not relevant for China (Shanghai) region.

- Self-registration of consumers
- Invitation of consumers
- Branding elements on all the forms for logon, registration, password update, and account activation

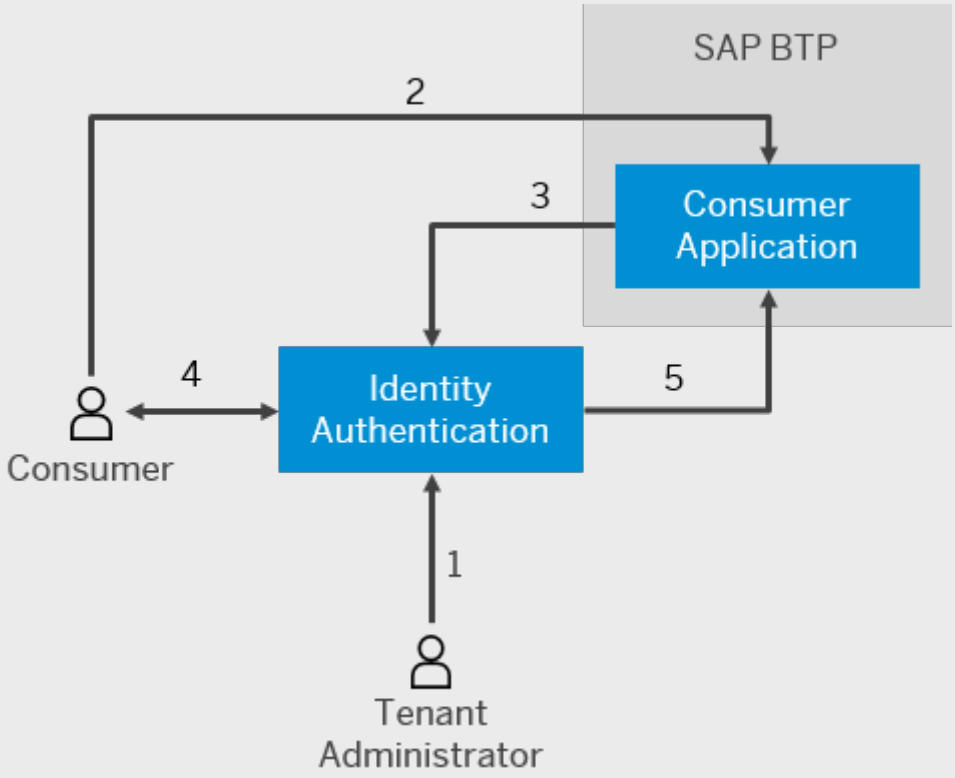
- Customized privacy policy and terms of use
- Consumer security policy
- User import and export

Example

Michael Adams is an administrator at retail company A. He would like to configure his system such that users can register on their own and then purchase from the company's site. Michael also wants to allow users to access his *Company A Purchasing* application by self-registration. To do this, Michael logs on to the administration console for SAP Cloud Identity Services, navigates to *Applications* > *Company A Purchasing*, and chooses *Authentication and Access* > *User Application Access*. He selects the *Public* radio button to allow user self-registration for his *Company A Purchasing* application. Michael also allows users to authenticate through a social provider by providing the keys and secrets for the social providers after he chooses the *Social Identity Providers* tile. He then enables social sign-on by choosing the *Applications* tile and navigating to *Company A Purchasing* > *Authentication and Access*. Furthermore, Michael configures custom terms of use and privacy policy for the *Company A Purchasing* application. To do this, he chooses the *Terms of Use Documents* and *Privacy Policy Documents* tiles and adds the new plain text files in English language versions. He then returns to *Applications* > *Company A Purchasing* view and sets the new terms of use and privacy policy documents for the application under the *Authentication and Access* tab.

Michael also decides to use a custom branding style for the buttons on his logon and registration forms. To do this, he opens the *Branding Style* page under the *Branding and Layout* tab in the *Application* view and selects the branding styles.

Donna Moore is a customer who wants to purchase goods from company A for the first time. When she accesses company A's application, she is redirected to the company's logon page. Because she is not registered yet, she has to choose the *Register Now* link to start the registration process. A registration form then appears, prompting Donna to enter her names, email, and address and to accept the organization's terms of use and privacy policy. When she submits the form, she receives an email with instructions on how to activate her registration. Once she activates her registration, she is able to log on to the retailing application with her user credentials.



1. Configures user access to the application.
2. Registers or provides credentials.
3. Delegates self-registration or authentication.
4. Activates account.
5. Confirms authentication.

Parent topic: User Engagement Scenarios [page 545]

Configuring Privacy Policies [page 2235]
Configuring Terms of Use [page 2273]
Choose and Configure a Branding Style for an Application [page 2035]

1.5.1.2 Business-to-Business

The business-to-business scenario is related to services for business partners. Unlike the business-to-consumer scenario, consumer self-registration is not allowed, and the administrator of the company is usually the one that triggers the user registration process.
The administrator invites partners or registers them on their behalf.

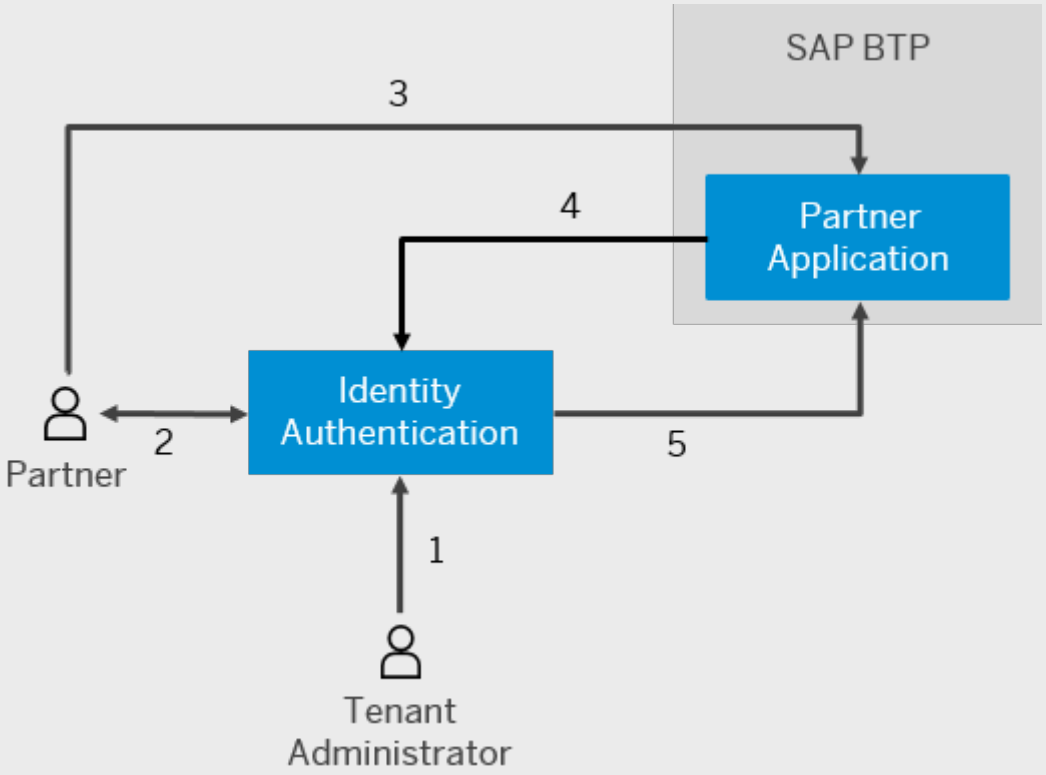
This scenario includes the following features:

- Authentication with user name and password
- A secure SSO to cloud applications
- Social sign-on to cloud applications

  > **Note**
  >
  > The content in this section is not relevant for China (Shanghai) region.

- Invitation of partners by administrators
- On-behalf registration of partners by administrators
- Branding elements on all the forms for logon, password update, and account activation
- Customized privacy policy and terms of use documents
- Partner security policy
- User import and export

> **Example**
>
> Donna Moore is a tenant administrator at company A. This company is a goods and services retailer. She would like to invite five transportation companies to join her organization in helping the distribution of goods and services to distant locations. The distributors will purchase from the *Company A Distribution* application. For this purpose, Donna registers these distributors on their behalf, logs on to the administration console for SAP Cloud Identity Services, navigates to *Applications* > *Company A Distribution* page, and chooses *Authentication and Access* > *User Application Access*. She selects the *Private* radio button in order to restrict access to just these users. The partners then activate their registration via the on-behalf registration email and can log on to the *Company A Distribution* application.



1. Invites or registers partner.
2. Activates account.
3. Provides credentials.
4. Delegates authentication.
5. Confirms authentication.

Business-to-Employee [page 550]
Administration [page 1918]
Development [page 2779]
Configure User Access to the Application [page 2025]

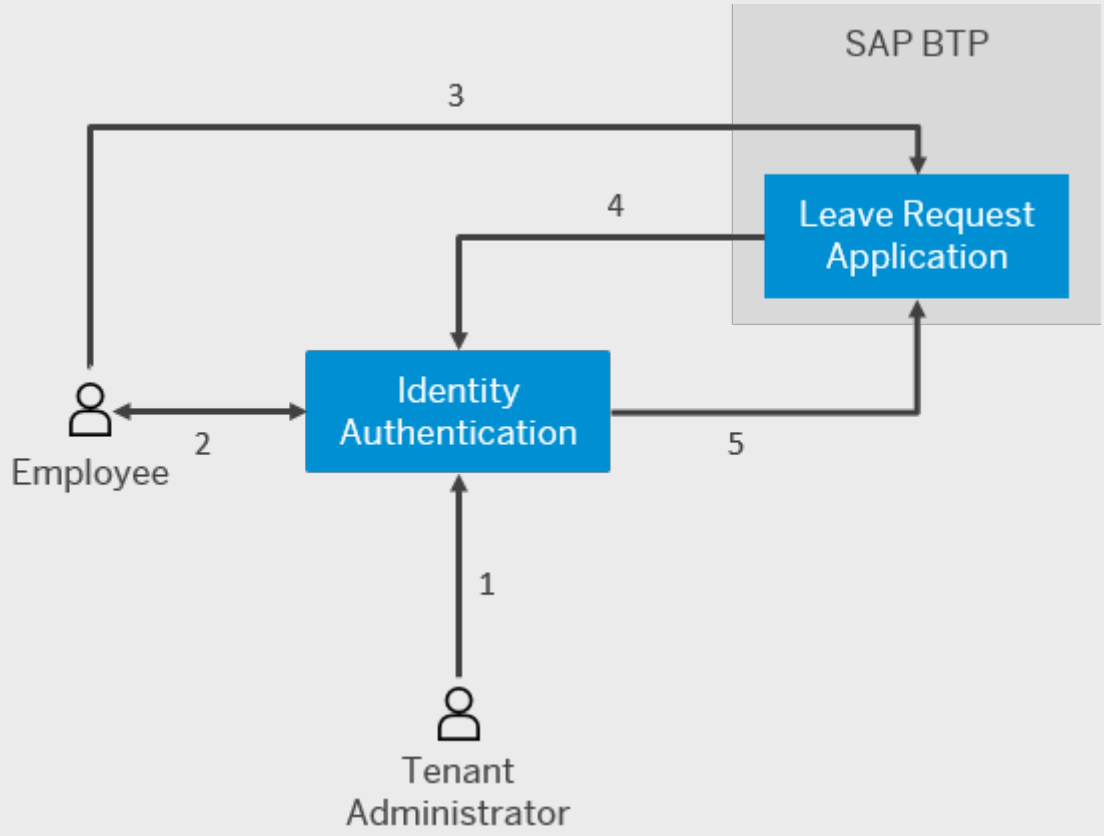
1.5.1.3 Business-to-Employee

The business-to-employee scenario is related to services for employees of an organization. Employees can access various applications with one logon. Furthermore, administrators can upload employees data by using the user import functionality.

The scenario includes the following features:

- Authentication with user name and password
- A secure SSO to cloud applications
- Branding elements on all the forms for logon and password update
- Customized privacy policy and terms of use documents
- Employee security policy
- User import and export
- Database restricted for employees only

> **Example**
>
> Julie Armstrong is an administrator at company B. She wants to configure a leave request application to be used by the employees of the company. For this purpose, she imports the employees by opening the *Import Users* page in the administration console for SAP Cloud Identity Services and selecting a CSV file containing the employees. Once she has imported all the new users into the system, she sends them an email with instructions how to activate their accounts. She also configures the trust on SAP BTP.
>
> Julie wants only the employees to access the application. She selects the *Internal* radio button after she chooses *Authentication and Access* > *User Application Access* for the leave request application in the administration console.
>
> As an employee of company B, Michael accesses an SAP BTP application to make a leave request. When he opens the application, he has to choose the *Forgot Password* link to activate his account. After activation, Michael provides a user name and password to log on to the leave request application with. He is redirected to Identity Authentication for authentication. Identity Authentication verifies his credentials and sends a response back to the SAP BTP application. As a result, Michael logs on and enters his leave request.



1. Imports users.
2. Activates account.
3. Provides credentials.
4. Delegates authentication.
5. Confirms authentication.

1.5.2 Onboarding and Provisioning

Onboard your users and groups into the Identity Directory to enable SAP Cloud Identity Services for secure authentication, authorization, and identity lifecycle management.

This section describes the available onboarding and provisioning scenarios and the corresponding configuration steps. It explains how to create and manage users and groups in the Identity Directory, configure centralized provisioning scenarios that use the Identity Directory as the central identity store, and automatically provision application-specific groups from the Identity Directory to target systems whenever changes occur.

User and Group Creation in Identity Directory [page 552]
Learn how to create users and groups in the Identity Directory — the persistency layer of SAP Cloud Identity Services.

Centralized Provisioning with Identity Directory [page 554]
Identity Directory is the persistency layer of SAP Cloud Identity Services, providing a central place for storing and managing users and groups. You can use it in centralized provisioning scenarios for managing user access to SAP cloud applications from a single, central location.

Central Store-Based Provisioning [page 579]
Central store-based provisioning enables the automatic provisioning of application-specific groups from the Identity Directory to the target systems whenever changes occur. These changes include user assignments or modifications of group attributes.

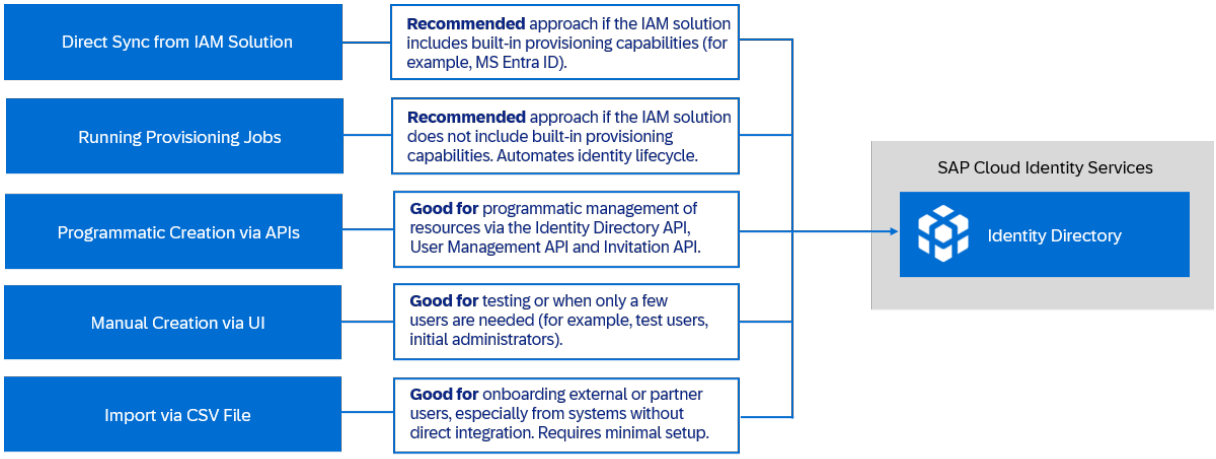
User Engagement Scenarios [page 545]
Identity and Access Management for Joule [page 580]

1.5.2.1 User and Group Creation in Identity Directory

Learn how to create users and groups in the Identity Directory — the persistency layer of SAP Cloud Identity Services.

We strongly recommend creating users in SAP Cloud Identity Services. In certain scenarios, such as when using Joule, SAP Task Center, or SAP SuccessFactors People Analytics, having users in SAP Cloud Identity Services is mandatory. Integrations with Joule and SAP Task Center require user persistence in the directory to enable cross-application correlation.

The diagram below outlines the available methods for onboarding users and groups, depending on your use case and goals.



Direct Sync from IAM Solution

Users and groups are provisioned through synchronization with the identity and access management (IAM) solution (direct sync), provided that both systems support the integration.

The IAM solution (for example, Microsoft Entra ID) includes built-in capabilities to provision users directly to the Identity Directory of SAP Cloud Identity Services. This allows users to authenticate via SAP Cloud Identity Services and access other SAP applications. For more information, see Configure SAP Cloud Identity Services for automatic user provisioning with Microsoft Entra ID .

Running Provisioning Jobs

Users and groups are created by executing scheduled or manual provisioning jobs from source systems in Identity Provisioning.

The Identity Provisioning service provides connectors to configure the synchronization of users and groups to the Identity Directory, and from there, transfer them to other SAP applications. For more information, see Centralized Provisioning with Identity Directory→ Source-Target System Provisioning.

Programmatic Creation via APIs

Users and groups can be provisioned programmatically using the Identity Directory SCIM API. Additionally, SAP Cloud Identity Services provide the Invitation REST API and the User Management REST API, which allow you to manage specific tasks programmatically, such as sending user invitations, registering users for specific applications.

For more information, see:

- Using the Identity Directory SCIM: Identity Directory API
- Using the Invitation REST API: Invitation REST API
- Using User Management REST API: User Registration

Manual Creation via UI

Users and groups are created manually through the directory's user interface in the SAP Cloud Identity Services administration console.

For more information, see Create a New User and Create a Group [page 2398].

Import via CSV File

Users and groups are imported using CSV file uploads in the SAP Cloud Identity Services administration console.

User import is supported at both the tenant level and the application level.

- **Tenant-level import** is typically used for users who will be managed centrally across multiple applications. For more information, see Import CSV File with Full User Profile
- **Application-level import** is used when only a subset of users needs access to a specific application. For more information, see Import or Update Users for a Specific Application

Group import is only supported at the tenant level.

For more information, see Import Groups via CSV File [page 2395]

Parent topic: Onboarding and Provisioning [page 552]

Related Information

Centralized Provisioning with Identity Directory [page 554]
Central Store-Based Provisioning [page 579]

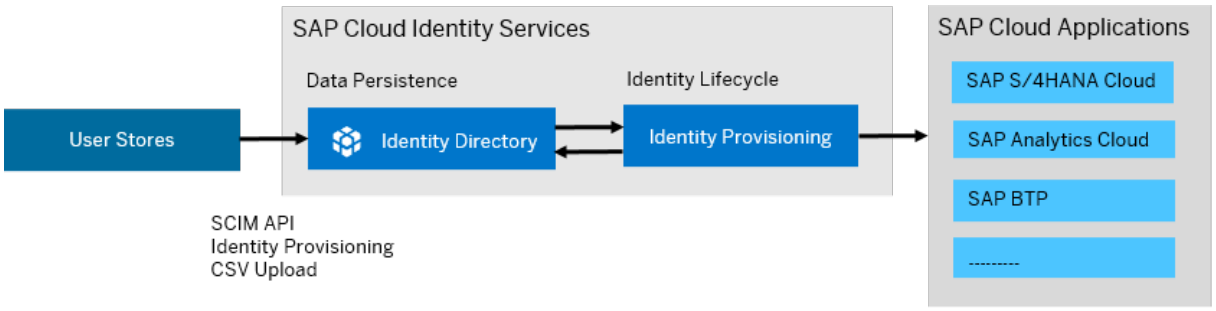
1.5.2.2 Centralized Provisioning with Identity Directory

Identity Directory is the persistency layer of SAP Cloud Identity Services, providing a central place for storing and managing users and groups. You can use it in centralized provisioning scenarios for managing user access to SAP cloud applications from a single, central location.

In a typical scenario, illustrated in the diagram below, the Identity Provisioning service reads identities from the customer's user store, like Microsoft Entra ID, and replicates them to the directory. From there, they are

provisioned further to various SAP cloud systems like SAP S/4HANA Cloud Public Edition, SAP Analytics Cloud and more.

For every newly created user, the directory generates a Global User ID, which serves as unique identifier across the entire landscape. This unique correlation attribute is then distributed by Identity Provisioning to the SAP cloud applications that need it for their integration with the SAP Task Center, for example. The unique identifier can also be generated externally and persisted in the identity directory during the initial replication from the customer's user store. For more information, see Global User ID in Integration Scenarios.



You can access the Identity Directory in the following ways:

- Use the Identity Provisioning service to create, update and delete users and groups by running provisioning jobs. The service provides a connector, known as Local Identity Directory, which can be set up as the source, target or proxy system for provisioning scenarios. There is no need to configure connectivity and authentication properties when connecting the Identity Directory and Identity Provisioning. Both services share the same SAP Cloud Identity Services tenant that you are currently logged in.
  For more information, see Local Identity Directory [page 957].

  > **Note**
  >
  > The Local Identity Directory connector is available for bundle and standalone tenants running on SAP Cloud Identity Services infrastructure.

- Use the SCIM 2.0 API to programmatically access and manage identities in the directory. The API allows you to view predefined schemas and to define custom schemas with your own attributes. For more information, see Identity Directory API.
- Use the SAP Cloud Identity Services administration console to access and manage identities in the directory via the user interface. For more information, see Managing Users [page 2342] and Managing Groups [page 2393].

Source-Target System Provisioning

Configure Local Identity Directory, both as a target and as a source system.

In this scenario, the Local Identity Directory is initially set up as a target system for user and group provisioning. Typically, identities are initially provisioned from the customer's user store to the directory, thus establishing the user store as the leading source system for identity management. Following this, users and groups from other source systems are provisioned to the directory. Finally, the identities in the directory are replicated to the target systems.

The following configuration example uses a number of systems, including: Microsoft Entra ID, Local Identity Directory, and SAP S/4HANA Cloud Public Edition.

1. Sign in to SAP Cloud Identity Services administration console and navigate to *Identity Provisioning*.
2. Add Microsoft Entra ID [page 914] as a source system.
3. Add Local Identity Directory [page 957] as a target system.
4. **Optional**: Configure properties that are relevant for the Local Identity Directory target system, for example `idds.support.bulk.operation` and `idds.bulk.operations.max.count`. For more information, see List of Properties [page 80].
5. **Optional**: Review and adapt the default write transformations as necessary.

6. Schedule or run manually a provisioning job [page 2472] from the *Microsoft Entra ID* source system.
7. View the provisioning job logs [page 2982] and subscribe to receive job notifications [page 3018]. We recommend that you do this for each source system where a provisioning job is initiated.
8. Add Local Identity Directory [page 957] as a source system.
   It already contains all the users and groups provisioned from *Microsoft Entra ID*.
9. **Optional**: Configure properties that are relevant for the Local Identity Directory source system, for example `idds.user.filter` and `idds.group.filter`. For more information, see List of Properties [page 80].
10. **Optional**: Review and adapt the default read transformations as necessary.

                "optional": true
            }
        ]
    }
}
```

11. Add SAP S/4HANA Cloud Public Edition [page 833] as a target system.
12. Start another provisioning job, this time from the *Local Identity Directory* source system.

Results

The Microsoft Entra ID users and groups are provisioned to the identity directory. It now becomes the central point of truth for identity information. Once in the directory, the users and groups are replicated to the SAP S/4HANA Cloud Public Edition target.

Merging Data from Multiple Sources

The personal and technical information of the user varies across different systems. To manage a unified and up-to-date user data, you can provision the identities from multiple sources and merge them into one target identity directory.

You can choose your own approach when merging data from various sources. This could include defining the unique attribute or a combination of them when resolving conflicts, as well as deciding on how to add and update user and group attributes. All of these require changes in the identity directory configuration.

> ⚠ Caution
>
> When reading user data from multiple sources, we strongly recommend that you perform **consecutive** provisioning jobs. Simultaneous jobs may lead to inconsistent or overwritten user data in the target system.

> ### Note
>
> To execute PATCH instead of PUT requests when updating an entry, set the `idds.support.patch.operation` = *true* on the *Properties* tab of the Local Identity Directory target system.

Merge Users by Email as Correlation Attribute

By default, Identity Provisioning determines the user uniqueness based on the `userName` attribute. This means that if a user with a particular `userName` already exists in the identity directory, the service will match any new user, provisioned from other source systems with the same `userName`, to this existing user and update it accordingly.

To merge the user data by email instead of userName, you only need to set the `idds.user.unique.attribute` to **`emails[0].value`**. For more information about the identity directory unique attributes supported for conflict resolution, see List of Properties [page 80] → `idds.user.unique.attribute`.

Merge User Attributes

Following the provisioning of your identities from the leading source system, you may want to replicate additional user attributes from the second source system which were not available in the first one.

To achieve this, we suggest that you configure two pairs of source-target systems. Each source system should point to the same identity directory instance, although both will have different configurations. For example, if Microsoft Entra ID (your leading source system) and Local Identity Directory 1 (target) make up your first pair, then the second pair could consist of SAP SuccessFactors (source) and Local Identity Directory 2 (target). This setup allows you to control which user attribute comes from which source system. The overall process is the following:

1. Create the first pair of source-target systems: *Microsoft Entra ID* > *Local Identity Directory 1*.
2. On the *Properties* tab of the target system set the `idds.support.patch.operation` = *true* and the `idds.user.unique.attribute` to a unique attribute of your choice.

   > ### Note
   >
   > The unique attribute you set for the `idds.user.unique.attribute` property can either be the same or different in each of your target systems. However, it must be unique in each case. For example, if userName and email are unique attributes, you can set **`userName`** in the *Local Identity Directory 1* and **`emails[0].value`** in the *Local Identity Directory 2*.

3. Modify the write transformation of the target system to provision particular user attributes. For example, keep the required `id`, `userName` and `emails`, as well as the `givenName`, `familyName`, `displayName` and `addresses`.

         }
   ]
},
"group":{
      "mappings":[

 .....
```

8. Run a second provisioning job, this time from SAP SuccessFactors, to replicate the identities to the same identity directory instance.
   This provisioning job will create new users in the Identity Directory from SAP SuccessFactors and update existing users with additional attributes from SAP SuccessFactors, specifically userType, department, division, perPersonUuid, and personIdExternal.

As a result, the identities from the two source systems are provisioned to a single target identity directory. Continuous provisioning jobs from both source systems run without overwriting attributes. Any updates are executed as patch requests.

Proxy System Provisioning

Configure *Local Identity Directory* as a proxy system in the Identity Provisioning.

You can use the identity directory as a SCIM 2.0 based proxy connector. Before exposing it to an external system, you should first populate it with users and groups. To learn how to read and then provision them to the identity directory, see the *Source-Target System Provisioning* section above.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API → *Filters*.

1. Sign in to SAP Cloud Identity Services administration console and create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning. If you already have a technical user, skip this step.
   - For **Certificate-based authentication**, follow the procedure in Manage Certificates for Inbound Connection [page 2456] → *SAP Cloud Identity Infrastructure*.
     For **Basic authentication**, navigate to *Users & Authorizations* > *Administrators* and add an admin user of type **System**. Configure a client ID and secret for this user and enable the *Access Proxy System API* permission.
2. Navigate to *Identity Provisioning* > *Proxy Systems*.
3. Add Local Identity Directory [page 1382] as a proxy system.
4. **Optional**: Configure properties applicable for the Local Identity Directory proxy system, such as `idds.user.filter` and `idds.group.filter`. For more information, see List of Properties [page 80].

5. **Optional**: Adapt the default proxy read and proxy write transformations:

6. Connect the external consumer to Identity Provisioning with the technical user you have created in *Step 1*. If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in *Step 1* and the SCIM assignment method as described below:
   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Results

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

1.5.2.3 Central Store-Based Provisioning

Central store-based provisioning enables the automatic provisioning of application-specific groups from the Identity Directory to the target systems whenever changes occur. These changes include user assignments or modifications of group attributes.

Prerequisites

To ensure the groups immediate provisioning to the target systems, the following application configurations are required:

- An application must be created for the relevant target system under *Applications & Resources* > *Applications*. See Create a New Application [page 1922].
- The application ID must be set as the value for the `ips.application.id` property in the target system. See List of Properties [page 80].
- The *Central Store-Based Provisioning* option must be enabled under *Applications & Resources* > *Applications* > *Provisioning*. See Enable or Disable Central Store-Based Provisioning [page 2401].

Context

You can initially create application-specific groups in the Identity Directory in the following ways: by running a provisioning job from a given source system, manually through the directory's user interface in the SAP Cloud Identity Services administration console or programmatically using the Identity Directory SCIM API.

For more information, see Groups [page 514] and User and Group Creation in Identity Directory [page 552].

When provisioning application-specific groups from the Identity Directory to target systems, groups that do not already exist in the target will be created. However, if you assign users to an application-specific group in the directory, this assignment will only be provisioned if the users already exist in the target system. Note that central store-based provisioning does not create users in the target system.

Procedure

Here is the necessary configuration to enable central store-based provisioning. The following example uses the Local Identity Directory as the source system and SAP Advanced Financial Closing as the target system.

1. Sign in to SAP Cloud Identity Services administration console and navigate to *Identity Provisioning*.
2. Add Local Identity Directory [page 604] as a source system.
3. **Optional**: Configure properties that are relevant for the Local Identity Directory source system, for example `idds.user.filter` and `idds.group.filter`. For more information, see List of Properties [page 80].
4. **Optional**: Review and adapt the default read transformations as necessary.
5. Add a target system of your choice, for example *SAP Advanced Financial Closing*.

6. Select the *Local Identity Directory* as relevant source system.
7. Set the property `ips.application.id` for the target system. For more information, see List of Properties [page 80].
8. Start a read job from the *Local Identity Directory* source system.
9. Navigate to your application in the administration console for SAP Cloud Identity Services under *Applications & Resources* > *Applications* and enable the *Central Store-Based Provisioning*. For more information, see Enable or Disable Central Store-Based Provisioning [page 2401].

Result

Once the procedure is executed, any change to an attribute value or a member of an application-specific group in the Local Identity Directory will trigger instant provisioning of the modified entity to the configured target system.

1.5.3 Identity and Access Management for Joule

Identity and access management architecture required for Joule, including the requirement for a single SAP Cloud Identity Services tenant, SAP-managed provisioning, and global user ID assignment. Understand this foundation before you implement Joule to ensure consistent authentication and authorization across all connected SAP applications.

> ⚠ Caution
>
> This page is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available to users outside of this program.

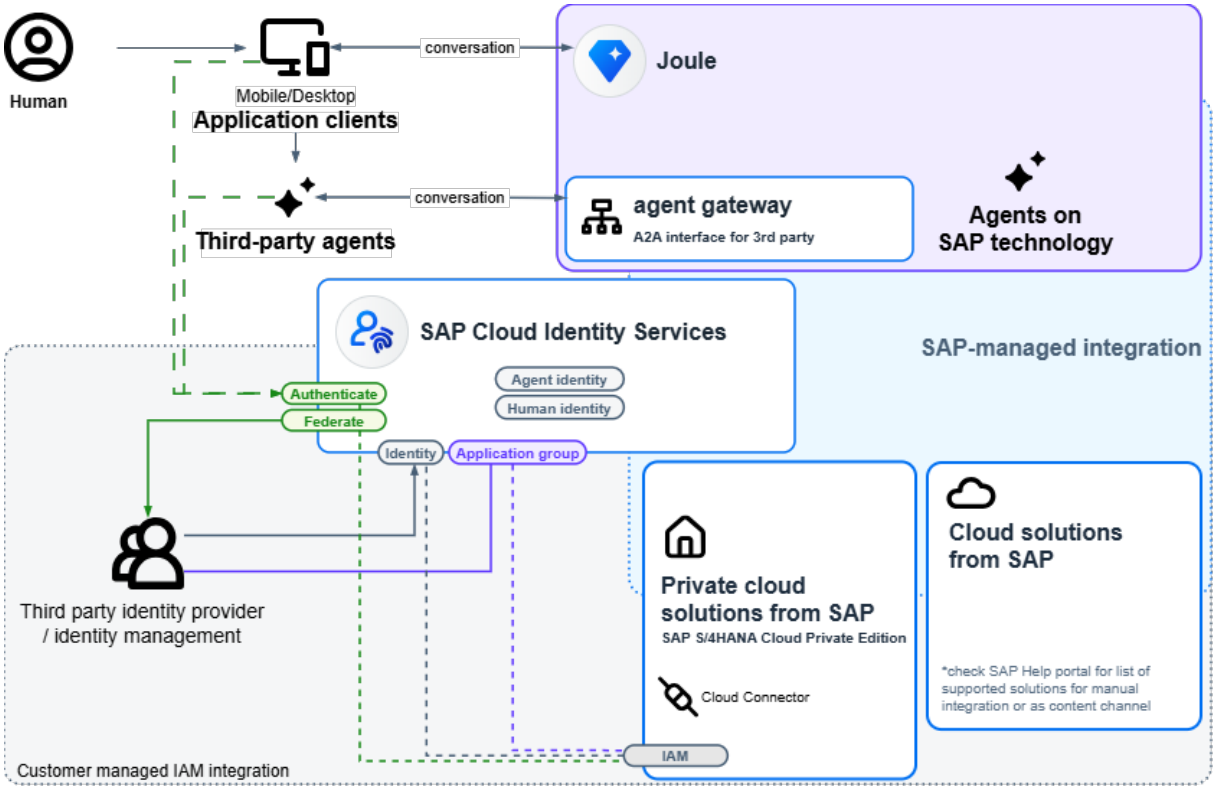
Joule, SAP's AI assistant, works across multiple connected SAP applications. For Joule to deliver a consistent experience, all of those applications must authenticate users through a single SAP Cloud Identity Services tenant. This makes SAP Cloud Identity Services the central identity and access management (IAM) layer across your SAP landscape. It forms the foundation on which you build Joule and any AI agents you deploy alongside it.

This topic explains the IAM architecture required for Joule. It covers why we designed it this way, what you need to put in place before you activate Joule, and how agent authentication and authorization fit into your

existing IAM model. The same principles apply whether your landscape is new or already has existing IAM configuration: a single SAP Cloud Identity Services tenant, users with global user IDs in the central directory, and trust established between each SAP application and that tenant.

> **Note**
>
> SAP Cloud Identity Services is included with SAP cloud applications at no additional charge. You don't need a separate subscription to use it for Joule.

SAP Cloud Identity Services is available to all customers for these scenarios automatically. No additional purchase is required.



SAP-Managed IAM Landscape for Joule

SAP-Managed IAM

SAP Cloud Identity Services supports SAP-managed identity integration across your SAP landscape. Without this approach, you must connect each SAP application to your identity layer individually. This means configuring trust, running provisioning jobs, and managing role assignments system by system. This costs you significant effort. With SAP-managed, SAP handles that configuration and keeps it running across software updates.

In the SAP-managed model, SAP takes responsibility for the technical integration. This includes setting up trust between SAP Cloud Identity Services and each connected SAP application, maintaining connector compatibility across product releases, running identity provisioning jobs, and replicating the global user ID back to each line-of-business (LoB) system. You retain control of business decisions. This includes choosing the identity provider, defining and assigning business roles, managing HR data, and configuring authentication policies.

SAP-managed IAM for Joule represents an initial step toward the same unified identity model used for the SAP Business Suite. In the Business Suite model, SAP Cloud Identity Services acts as the authoritative source for user and role data. The system distributes assignments outward to applications. The current Joule model adopts a pragmatic starting point. User records and group assignments originate in each LoB application. SAP reads them into SAP Cloud Identity Services and uses them to issue authorization tokens for Joule. The system then writes the global user ID back to the LoB system to link the records. The LoB system remains the authoritative source for user and role data in the current release. If you already follow the Business Suite model, this approach is consistent with the direction you are already heading. Fully centralized assignment management in SAP Cloud Identity Services is planned for a future release.

For Joule and the Business AI Platform, SAP-managed is the only supported integration path for public cloud applications. SAP handles the provisioning job configuration. You don't need any Identity Provisioning credentials for these systems. Identity Provisioning remains available for other applications in your landscape.

For more information, see SAP-Managed SAP Cloud Identity [page 520].

Shared Responsibilities

SAP Manages	You Manage
Connector compatibility	Identity provider selection
Infrastructure	Business role definition
Availability	User assignment
Trust setup	HR data management
Identity Provisioning job execution	Authentication policies
Global user ID replication	Agent access authorization

User Prerequisites and Business User Consolidation

For Joule to identify and authorize a user consistently across all connected SAP applications, that user must have a global user ID assigned in SAP Cloud Identity Services. The global user ID acts as the common identifier that links the user's records across different SAP systems. Joule can't recognize users without a global user ID in the central directory.

To get users into SAP Cloud Identity Services with their global user IDs and group assignments, SAP-managed identity provisioning runs two coordinated jobs for each connected LoB system:

> → Remember
>
> Before running the SAP-managed provisioning jobs, every user in scope must have logged in at least once to the LoB application using SAP Cloud Identity Services as the identity provider. This creates the application-user record that the provisioning job requires to perform consolidation correctly. Users who haven't yet logged in will have consolidatable user records created, but the system can't automatically merge those records with existing user profiles until the user signs in.

> ⚠ Caution
>
> EAC customers must currently import SAP-managed provisioning job templates manually. For more information, see . Job templates are available from SAP Note 3784171. (If you are part of the EAC program and need access to this SAP Note, open an incident under BC-IAM-IPS.)

1. A **read job** runs from the LoB system to SAP Cloud Identity Services. It reads user records and application-specific groups from the LoB system and creates corresponding entries in the SAP Cloud Identity Services user directory. Users created by this job are **consolidatable users**: shadow records that represent a user known to the LoB system but who hasn't yet logged in through SAP Cloud Identity Services. They are internal records maintained per application. A user with accounts in multiple LoB systems will have a separate consolidatable record for each. When the user logs in for the first time, the system merges the consolidatable user record with their full user profile and confirms the global user ID.
2. A **write-back job** runs from SAP Cloud Identity Services to the LoB system. It writes the global user ID assigned in SAP Cloud Identity Services back to the user record in the LoB system. This establishes the permanent link between the two records.

> ⓘ Note
>
> During user replication, only a minimal user representation is provisioned to and from the Identity Directory, indicating the source application from which the user originates. The primary purpose of this replication is to provide users with a consistent identity across connected SAP applications by assigning a Global User ID.

After the read job runs, you may need to resolve group conflicts before the write-back job can run. Group conflicts arise when the same group exists in both the Identity Directory and the LoB application and the system cannot automatically reconcile them.

After initial provisioning, your landscape is in **Stage 1**: connected applications and their roles appear in SAP Cloud Identity Services, consolidatable user records are present in the background, and Joule is available as a conversational AI assistant within the embedded user interface of each connected Business Application. In Stage 1, agents aren't available. They appear only when users have real identities in SAP Cloud Identity Services.

In **Stage 2**, real user identities exist in SAP Cloud Identity Services and are linked to application groups. Users with identities can be assigned to assistants and agents from the SAP Cloud Identity Services administration console or with the SCIM API. Stage 2 also unlocks the full Joule experience. LoB systems remain the authoritative source for user and role data until a future release.

> ⚠ Caution
>
> Agents are not available to users in Stage 1. If your SAP Cloud Identity Services tenant is new and contains no pre-existing user identities, your users will be limited to conversational Joule functions until Stage 2 is reached. We recommend creating user identities in SAP Cloud Identity Services before deploying Joule so that users have immediate access to agents after provisioning.

Whether you can advance to Stage 2 immediately after provisioning depends on your existing landscape:

- If SAP Cloud Identity Services already contains user identities with matching attributes (such as email address), the SAP-managed jobs match and link them automatically when they run. In this case, you can advance to Stage 2 as soon as provisioning completes.
- If SAP Cloud Identity Services is new with no existing user records, create user identities before deploying Joule. You can upload a .csv file, use the SCIM API, or create users manually in the SAP Cloud Identity

Services administration console. Once identities exist, the SAP-managed jobs match and link them automatically, and you reach Stage 2 after provisioning.

The user consolidation tool is a dedicated capability for transitioning users from Stage 1 to Stage 2 after initial provisioning. It presents administrators with suggested matches between consolidatable user records and real identities across applications, user by user, and requires explicit approval before creating the linked identity. This tool is not available at general availability (GA) but is planned for a future release. Until this tool becomes available, customers who deployed Joule with a new SAP Cloud Identity Services tenant and no pre-existing identities remain in Stage 1 and do not have access to agents.

If your landscape already includes user synchronization, for example, from SAP SuccessFactors to SAP Cloud Identity Services, those existing jobs continue independently. SAP-managed jobs for Joule create application-specific groups alongside existing configuration without conflicting with it.

> **Note**
>
> SAP SuccessFactors provisioning jobs create full user profiles rather than consolidatable users. Users provisioned from SuccessFactors are therefore treated differently during consolidation than users coming from other LoB systems.

Authentication Considerations

When you connect SAP applications to Joule, the subject name identifier (SNI) used for authentication in each application must align with the SAP-managed identity provisioning configuration. For most SAP applications, the SNI is the user's email address. If an application uses a different value as the SNI, for example, a login name or worker ID, you must adapt the identity provisioning job transformation to ensure users are matched correctly across systems. Application-specific SNI requirements are documented in the setup guidance for each LoB application.

If users in your landscape access SAP applications across different domain patterns, for example, some applications use the `ondemand.com` domain while others use `cloud.sap`, single sign-on sessions may not carry over automatically between domains. To resolve this, enable the *Sync SSO Cookie Between Domains* option in your SAP Cloud Identity Services tenant. You must also register any custom domains used in your landscape in the Joule Admin Center.

If you use a third-party identity provider such as Microsoft Entra ID or Okta, SAP Cloud Identity Services acts as a proxy between your identity provider and the connected SAP applications. All SAP applications connected to Joule must use the same SAP Cloud Identity Services tenant as their identity provider. Connecting a LoB application to a different SAP Cloud Identity Services tenant from the one used for Joule isn't supported.

1.6 Supported Systems

Identity Provisioning synchronizes users and groups between multiple supported cloud and on-premise systems, both SAP and non-SAP.

For more inforomation about the provisioning systems (connectors) available for use as *source*, *target*, and *proxy* system types, refer to the related topics within this section.

> **Note**
>
> This documentation refers to Identity Provisioning in the SAP Cloud Identity Services infrastructure. To access the service documentation in the Neo environment, go to Identity Provisioning Service in the Neo Environment.

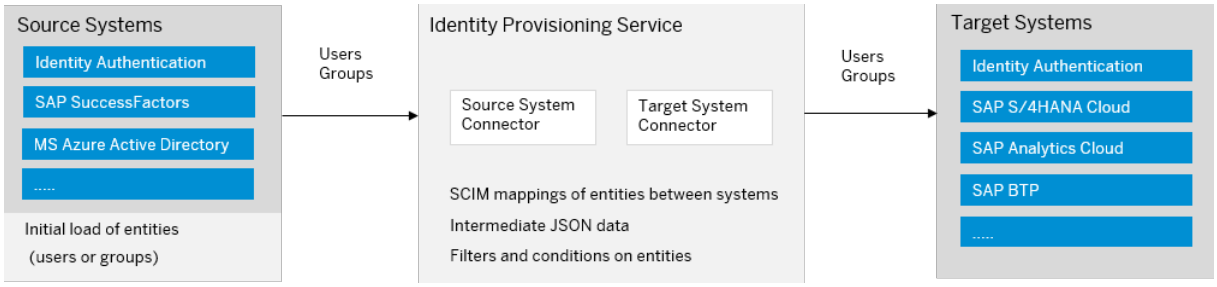
Proxy Systems [page 1343]

1.6.1 Source Systems

A source system is the connector used for reading entities (users, groups, roles).

Source systems can be on-premise or cloud-based, SAP or non-SAP, and usually represent the corporate user store where identities are currently maintained. Identity Provisioning reads the entities from the source system and creates or updates them in the relevant target ones. The provisioning is triggered from the *Jobs* tab of a source system.

You can connect one source system to one or multiple target systems. In the case of multiple (enabled) target systems, when you start a *Read* or a *Resync* job, this operation will trigger provisioning of entities from this source system to all relevant target ones.



> ⚠ Restriction
>
> By default, the maximum number of productive source systems you are allowed to add for your tenant is **20**. This restriction is valid for *Customer Managed* systems only.
>
> If your business requires using more systems, create an incident for component *BC-IAM-IPS* to request them. Describe your scenarios and provide a reason why you need the additional systems.

System Types [page 70]

1.6.1.1 Identity Authentication

Follow this procedure to set up SAP Cloud Identity Service – Identity Authentication as a source system.

Prerequisites

To establish the connection between Identity Provisioning and Identity Authentication, you need to set up the technical user (of type *System*) in Identity Authentication and assign this user the necessary authorizations. You have the option to do it either now, as a prerequisite, or while configuring Identity Authentication as a source system, as described in step 3.

Context

Identity Authentication provides authentication and single sign-on for users in the cloud. The user store of Identity Authentication can manage different type of users (employees, partners, customers and public) as well as groups. Using Identity Provisioning, you can read those users (self-registered, imported, or manually created) and groups and provision them to various target systems.

For this, you need to configure the Identity Authentication as a source system in the Identity Provisioning UI. This source system consumes SCIM 2.0 API provided by Identity Authentication.

There are two versions of the Identity Authentication SCIM API. They are handled by the `ias.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on July 9, 2021) - Identity Authentication SCIM API (in short, SCIM API version 1) is used.

  > ⓘ Note
  >
  > The SAP Cloud Identity Services – Identity Authentication SCIM API (version 1) will be decommissioned on November 30, 2028. You must use its successor, the Identity Directory SCIM API.

This requires updating your Identity Authentication connector from version 1 to version 2, as described in Update Connector Version [page 2424].

- When the value is set to **2** - Identity Directory SCIM API (in short, SCIM API version 2) is used. This value is set automatically for all manually created systems in the as a source system. For more information, see Identity Provisioning UI after versioning was introduced on July 9, 2021.
  SCIM API version 2 is enhanced to support paging for group members and user's groups, custom attributes, delta read mode for users. Also, the group resource mapping in the transformation is not ignored by default, as it is in SCIM API version 1.

  > **Note**
  >
  > Identity Authentication (using SCIM API version 2) and Identity Directory are sometimes used interchangeably. Identity Directory is the persistency layer of SAP Cloud Identity Services – Identity Authentication.

To create Identity Authentication as a source system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Identity Authentication* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning as a source system and Identity Authentication and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added Identity Authentication source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Manage Certificates [page 2450].

      Skip step **a.** if you want to use basic authentication.

      In SAP Cloud Identity Services administration console, perform the next steps. They are relevant for both basic and certificate-based authentication.

   b. Add System as administrator and provide the respective credentials.

      For basic authentication, provide a password. The user ID will be generated automatically when you set the password for the first time.

      For certificate-based authentication, upload the certificate you have generated in SAP Cloud Identity Services administration console on the previous step.

   c. Save your changes.

   d. Make sure *Manage Users* (or at least *Read Users*) and *Manage Groups* authorization roles are enabled for the technical user. This way, you can read users and groups from the Identity Authentication user store.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL of the Identity Authentication tenant of your company. For example: **https://mytenant.accounts.ondemand.com** **Note** If your Identity Authentication Shanghai (China) tenants reside on SAP BTP, Neo, you should use the following URL pattern: *https://<tenant_ID>.accounts.sapcloud.cn/*
`ProxyType`	Enter: *Internet* The Identity Authentication service is a cloud solution and is outside of your company on-premise infrastructure.
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the Client ID (previously User ID) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*. For example: *1ab7c243-5de5-4530-8g14-1234h26373ab* If your technical user was created before *January 2020*, enter the T-user. For example: *T000003*
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the Client Secret (previously Password) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*.

Optional Properties

Property Name	Description & Value
• `ias.<property_name>` • `scim.<property_name>`	When using SCIM API version 2, property names start with `ias` prefix, for example: `ias.user.unique.attribute`. When using SCIM API version 1, property names start with `scim` prefix, for example: `scim.user.unique.attribute`. For more information, see List of Properties [page 80]. Use the main search or filter properties by *Name* or *System Type* columns.
`ias.user.filter`	When specified, only those users matching the filter expression will be read. For example: **name.familyName eq "Smith" and addresses.country eq "US"** This filter will read only users whose name is "*Smith*" and are living in the *United States*. For more information, see Identity Directory SCIM API: User Search.
`ias.group.filter`	When specified, only those groups matching the filter expression will be read. For example: **displayName eq "ProjectTeam1"** This filter will read only groups, whose display name is "*ProjectTeam1*". For more information, see Identity Directory SCIM API: Group Search.
`ips.failed.request.retry.attempts`	Predefined value: *2*
`ips.failed.request.retry.attempts.interval`	Predefined value: *60*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Identity Authentication* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   When Identity Authentication is configured as a source system, the default transformation logic reads all the user attributes from the Identity Authentication user store. The logic is provided by the Identity Authentication SCIM REST API, which then maps the attributes to the internal SCIM representation.

Handling Application-Specific Groups

In case you want to provision application-specific groups between the following pairs of provisioning systems:

Source System	Target System
Identity Authentication (SCIM API version 2)	Identity Authentication (SCIM API version 2)
Identity Authentication (SCIM API version 2)	Local Identity Directory
Local Identity Directory	Identity Authentication (SCIM API version 2)

The Identity Provisioning will search and try to resolve the groups by the attribute values of `displayName`, `applicationId`, and `type`. To ensure successful provisioning, you must define value mappings for the attribute `applicationId` in the transformation mappings of the source or the target system. You should define to which `applicationId` in the target system will be mapped the `applicationId` read from the source system.

For example:

```
{
"sourcePaths": [
    "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']"
],
"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']",
"valueMappings": [
    {
        "key": [
            "<your_source_system_applicationId>"
        ],
        "mappedValue": "<your_target_system_applicationId>"
    }
    ],
    "condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
    "type": "valueMapping",
    "defaultValue": ""
}
```

For more information, see Transformation Expressions [page 391] → section **valueMapping**.

You can change the default transformation mapping rules to reflect your current setup of entities in your Identity Authentication system. For more information, see: Manage Transformations [page 2439]

SCIM API version 1: Identity Authentication: SCIM REST API

SCIM API version 2: Identity Directory SCIM API

> **Note**
>
> When a user is deleted from the Identity Authentication, the deletion status is considered by it during the read processes. Depending on the off-boarding user handling in the target system, a user can be deleted, or can be set to *inactive*.

Default transformation for SCIM API version 1:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem",
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['userId']"
            },
            {
                "sourcePath": "$.userUuid",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true
            },
            {
                "sourcePath": "$.name.middleName",
                "targetPath": "$.name.middleName",
                "optional": true
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName",
                "optional": true
            },
            {
                "sourcePath": "$.name.honorificPrefix",
                "targetPath": "$.name.honorificPrefix",
                "optional": true
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true,
                "defaultValue": true
            },
            {
                "sourcePath": "$.userType",
```

```
                "targetPath": "$.userType",
                "optional": true
            },
            {
                "sourcePath": "$.addresses",
                "targetPath": "$.addresses",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.locale",
                "targetPath": "$.locale",
                "optional": true
            },
            {
                "sourcePath": "$.phoneNumbers",
                "targetPath": "$.phoneNumbers",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.timeZone",
                "targetPath": "$.timezone",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true
            },
            {
                "sourcePath": "$.sourceSystemId",
                "targetPath": "$.sourceSystemId",
                "ignore": true
            },
            {

        ]
    }
}
```

6. Add a target system where to provision users and groups. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.2 Intelligent Opportunity Analyzer

Follow this procedure to set up intelligent opportunity analyzer as a source system.

Prerequisites

You have created an instance and generated a service key for the *scim* service plan of *Intelligent Opportunity Analyzer*. For more information, see Assigning the Entitlements for Intelligent Opportunity Analyzer to Your Subaccounts.

Context

Intelligent opportunity analyzer is a service that comes integrated with SAP Ariba Category Management for identifying and managing opportunities that lead to improving the performance of a purchasing category.

You can use Identity Provisioning to configure intelligent opportunity analyzer as a source system where you can read users from and provision them to a target system.

> **Note**
>
> Intelligent opportunity analyzer does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Intelligent Opportunity Analyzer* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key. Ensure to append the value `/oauth/token?grant_type=client_credentials`.
(Optional) `ioa.user.filter`	When specified, only those intelligent opportunnity analyzer users matching the filter expression will be read. For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Intelligent Opportunity Analyzer* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source intelligent opportunity analyzer system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   > ### Note
   >
   > The documentation for the Intelligent Opportunity Analyzer API and its integration with Identity Provisioning is still under development. Refer to the Intelligent Opportunity Analyzer Setup for updates.

   Default transformation:

   ### Code Syntax

   ```
   {
     "user":{
       "mappings":[
         {
           "sourcePath":"$.id",
           "targetVariable":"entityIdSourceSystem"
         },
         {
   ```

```
        "sourcePath":"$.schemas",
        "targetPath":"$.schemas",
        "preserveArrayWithSingleElement":true
      },
      {
        "sourcePath":"$.userName",
        "targetPath":"$.userName",
        "correlationAttribute":true
      },
      {
        "sourcePath":"$.loginName",
        "targetPath":"$.loginName",
        "optional":true
      },
      {
        "sourcePath":"$.name.givenName",
        "targetPath":"$.name.givenName",
        "optional":true
      },
      {
        "sourcePath":"$.name.familyName",
        "targetPath":"$.name.familyName",
        "optional":true
      },
      {
        "sourcePath":"$.name.formatted",
        "targetPath":"$.name.formatted",
        "optional":true
      },
      {
        "sourcePath":"$.name.middleName",
        "targetPath":"$.name.middleName",
        "optional":true
      },
      {
        "sourcePath":"$.name.honorificPrefix",
        "targetPath":"$.name.honorificPrefix",
        "optional":true
      },
      {
        "sourcePath":"$.name.honorificSuffix",
        "targetPath":"$.name.honorificSuffix",
        "optional":true
      },
      {
        "sourcePath":"$.emails",
        "targetPath":"$.emails",
        "preserveArrayWithSingleElement":true
      },
      {
        "sourcePath":"$.emails[?(@.primary== true)].value",
        "correlationAttribute":true
      },
      {
        "sourcePath":"$.active",
        "targetPath":"$.active"
      },
      {
        "sourcePath":"$.displayName",
        "targetPath":"$.displayName",
        "optional":true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
```

```
        }
      ]
    }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.3 Local Identity Directory

Follow this procedure to set up Local Identity Directory as a source system.

Prerequisites

> **Note**
>
> The *Local Identity Directory* connector is available for both bundle and standalone tenants running on SAP Cloud Identity Services infrastructure.

Context

Identity directory is the user store of SAP Cloud Identity Services. It provides a central place for storing and managing users, groups and custom schemas through the System for Cross-domain Identity Management 2.0 REST API, in short Identity Directory SCIM API.

You can read users and groups from the identity directory and provision them to various target systems by configuring the Local Identity Directory connector as a source system in the SAP Cloud Identity Services administration console. The entities are read from the identity directory of your current SAP Cloud Identity Services tenant. Therefore, you don't have to set up connectivity and authentication properties for the source system. In case you want to read entities from the identity directory in another tenant, add Identity Authentication (version 2) as a source system and configure the respective connectivity and authentication properties.

To create Local Identity Directory as a source system, proceed as follows:

Procedure

1. Sign in to SAP Cloud Identity Services administration console and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Local Identity Directory* as a source system.

   For more information, see Add New Systems [page 2415].
3. **Optional:** If needed, choose the *Properties* tab to configure filtering and paging.

   Optional Properties

Property Name	Value
`idds.user.filter`	This property filters users by particular attributes. You can set a single attribute or multiple ones as search criteria. • Value pattern for single attribute: *<user_attribute> eq "<value>"* • Value pattern for multiple attributes: *<user_attribute1> eq "<value1>" and/or <user_attribute2> eq "<value2>"*
`idds.group.filter`	This property filters groups by display name. You can set a single display name or multiple ones as filter criteria. If you enter multiple display names (using **OR** operator), the filter will search for any of them. • Value pattern for single attribute: *displayName eq "<group_name>"* • Value pattern for multiple attributes: *displayName eq "<group_name1>" or displayName eq "<group_name2>"*
`idds.user.groups.paging.enabled`	This property enables paging of user's groups. The maximum number of user's groups returned per request is 1000. To read more than 1000 user's groups, paging must be enabled.
`idds.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 20 000. To read more than 20 000 group members, paging must be enabled.

   Local Identity Directory properties are prefixed with `idds.<property_name>`. For more information, see List of Properties [page 80].
4. **Optional:** Configure transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the Local Identity Directory source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

When Local Identity Directory is configured as a source system, the default transformation logic reads the user attributes from the user store of SAP Cloud Identity Services. The logic is provided by the Identity Directory SCIM API, which then maps the attributes to the internal SCIM representation.

Handling Application-Specific Groups

In case you want to provision application-specific groups between the following pairs of provisioning systems:

Source System	Target System
Identity Authentication (SCIM API version 2)	Identity Authentication (SCIM API version 2)
Identity Authentication (SCIM API version 2)	Local Identity Directory
Local Identity Directory	Identity Authentication (SCIM API version 2)

The Identity Provisioning will search and try to resolve the groups by the attribute values of `displayName`, `applicationId`, and `type`. To ensure successful provisioning, you must define value mappings for the attribute `applicationId` in the transformation mappings of the source or the target system. You should define to which `applicationId` in the target system will be mapped the `applicationId` read from the source system.

For example:

```
{
"sourcePaths": [
    "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']"
],
"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']",
"valueMappings": [
    {
        "key": [
            "<your_source_system_applicationId>"
        ],
        "mappedValue": "<your_target_system_applicationId>"
    }
    ],
    "condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
    "type": "valueMapping",
    "defaultValue": ""
}
```

For more information, see Transformation Expressions [page 391] → section **valueMapping**.

You can change the default transformation mapping rules to reflect your current setup of entities in your Local Identity Directory. For more information, see:

- Manage Transformations [page 2439]
- SCIM API version 2: Identity Directory SCIM API

Default transformation for Local Identity Directory:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem",
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['userId']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userId']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userId']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true
            },
            {
                "sourcePath": "$.name.middleName",
                "targetPath": "$.name.middleName",
                "optional": true
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName",
                "optional": true
            },
            {
                "sourcePath": "$.name.honorificPrefix",
                "targetPath": "$.name.honorificPrefix",
                "optional": true
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "correlationAttribute": true
```

```
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.userType",
                "targetPath": "$.userType",
                "optional": true
            },
            {
                "sourcePath": "$.addresses",
                "targetPath": "$.addresses",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.locale",
                "targetPath": "$.locale",

['purchasingOrganization']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap.odm:2.0:User']
['purchasingOrganization']",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap.odm:2.0:User']
['purchasingGroup']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap.odm:2.0:User']
['purchasingGroup']",
                "preserveArrayWithSingleElement": true,
                "optional": true
            }
        ]
    },
    "group": {
```

```
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']",
                "optional": true
            },
            {
                "sourcePath": "$

['supportedOperations']",
                "optional": true
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']",
                "optional": true
            }
        ]
    }
}
```

5. Add a target system where to provision users and groups. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.4 SAP Advanced Financial Closing

Follow this procedure to set up a SAP Advanced Financial Closing as a source system.

Prerequisites

You have created an instance and generated a service key for the standard service plan of SAP Advanced Financial Closing. For more information, see: How to Manage User Access Using the SCIM API Provided.

The service key contains the API URL and the OAuth credentials (`clientid` and `clientsecret`) under the `uaa` property.

Context

SAP Advanced Financial Closing allows you to define, automate, process, and monitor the financial closing tasks for the entities of your organization. It is an SAP BTP application that runs in an SAP BTP subaccount.

You can use Identity Provisioning to configure SAP Advanced Financial Closing as a source system where you can read users, user groups and user roles from, and provision them to a target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Advanced Financial Closing* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
Type	Enter: *HTTP*

Property Name	Value
`URL`	Enter the URL provided by the service key under *endpoints* > *scim2* without adding the path information. For example: `https://afc-production-afc-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user ID provided by the service key under *uaa* > *clientid*.
`Password`	(Credential) Enter the password provided by the service key under *uaa* > *clientsecret*.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL provided by the service key of your SAP Advanced Financial Closing instance. It follows the pattern: **`<uaa.url>/oauth/token`**, where: • `<uaa.url>` is the URL provided by the service key under *uaa* > *url*. • **`/oauth/token`** is the suffix you need to add.
(Optional) `s4hana.afc.user.filter`	When specified, only those SAP Advanced Financial Closing users matching the filter expression will be read. Supported operators: **`eq`** (equal), **`sw`** (starts with) and **`co`** (contains) For example: • *userName eq "Julie Armstrong"* • *emails eq "julie.armstrong@example.com"* • *name.familyName sw "A"* • *name.givenName co "Ju"*
(Optional) `s4hana.afc.group.filter`	When specified, only those SAP Advanced Financial Closing groups matching the filter expression will be read. Supported operators: **`eq`** (equal), **`sw`** (starts with) and **`co`** (contains) For example: *displayName eq "Administrators"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the SAP Advanced Financial Closing source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Advanced Financial Closing. For more information, see Manage Transformations [page 2439].

How to Manage User Access Using the SCIM API Provided

SAP Business Accelerator Hub: SAP Advanced Financial Closing

> ### Note
>
> When configuring SAP Advanced Financial Closing as a source system, there may be a mismatch between optional user attributes in the source system and required user attributes in the target system. For example, the email is an optional attribute in SAP Advanced Financial Closing but a required one in Identity Authentication. In such cases, you need to review and adapt your source and/or target system transformations and configurations to reflect your needs.

Default transformation:

> ### Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$

            "function": "concatString",
            "prefix": "%s4hana.afc.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      }
    ]
  }
}
```

5. Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.5 SAP Advanced Workflow

Follow this procedure to set up a source connector for SAP Advanced Workflow.

Prerequisites

- You have technical credentials for SAP Advanced Workflow. Note that SAP Advanced Workflow is available to SAP SuccessFactors Incentive Management customers as an optional add-on. You create an Admin user in SAP SuccessFactors Incentive Management, which is synchronized with SAP Advanced Workflow. For more information, see: Adding an Admin User and Commissions User Synchronization.
- You have set up SSO between Identity Authentication and SAP Advanced Workflow. For more information, see Integration with SAP IdP.

Context

SAP Advanced Workflow enables you to analyse, organize, and execute business processes to connect people, data, and daily activities. Workflow provides you the tools you need to configure and customize your business processes based on your specific business needs.

After fulfilling the prerequisites, follow the procedure below to add a source system for SAP Advanced Workflow where you can read **users** from and provision them to a target system. This source system consumes Workflow SCIM API.

> **Note**
>
> SAP Advanced Workflow does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Advanced Workflow* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Advanced Workflow system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP Advanced Workflow system.
`Password`	(Credential) Enter the password for your SAP Advanced Workflow user.
`awf.domain`	The domain name is the name of your SAP Advanced Workflow tenant. If you don't know your tenant name, contact your supervisor or administrator, or refer to the email notification you received when your account was created.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Advanced Workflow* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see:

   Manage Transformations [page 2439]

   The behavior of the default transformation logic is to read all user attributes from the source SAP Advanced Workflow system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
```

```
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.middleName",
                "optional": true,
                "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.phoneNumbers[0].value",
                "optional": true,
                "targetPath": "$.phoneNumbers[0].value"
            },
            {
                "sourcePath": "$.profileUrl",
                "targetPath": "$.profileUrl",
                "optional": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true
            },
            {
                "sourcePath": "$.emails[0].value",
                "optional": true,
                "targetPath": "$.emails[0].value"
            },
            {
                "sourcePath": "$.timezone",
                "targetPath": "$.timezone",
                "optional": true
            }
        ]
    }
}
```

5. Now, add a target system to provision users and their group assignments to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.6 SAP Analytics Cloud

Follow this procedure to set up SAP Analytics Cloud as a source system.

Prerequisites

- In SAP Analytics Cloud, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- Add an OAuth client with authorization grant **Client Credentials**. To learn how, see: Managing OAuth Clients and Trusted Identity Providers

Context

SAP Analytics Cloud is an all-in-one cloud product offered as software as a service for business intelligence, planning, and predictive analytics.

You can use Identity Provisioning to configure SAP Analytics Cloud as a source system where you can read users and groups and provision them to target systems of your choice. The source system consumes SCIM 2.0 API provided by SAP Analytics Cloud.

There are two versions of the SAP Analytics Cloud SCIM API. They are handled by the `sac.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on April 10, 2023), SAP Analytics Cloud SCIM API version 1 is used. This is the default value.
- When the value is set to **2** - SAP Analytics Cloud SCIM API version 2 is used. This version is released with enhancements, such as: reading groups is not ignored in the default read transformation.

For more information on the differences between SAP Analytics Cloud SCIM API version 1 and 2, see Managing Users and Teams.

For more information on how to update to version 2, see Update Connector Version [page 2424].

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Analytics Cloud* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Analytics Cloud system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Analytics Cloud.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Analytics Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Analytics Cloud instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page. For more information, refer to *Authorize API Access for OAuth Clients* in Manage OAuth Clients
(Optional) `sac.api.version`	Handles the version of SAP Analytics Cloud SCIM API. **Possible values:** • *1* - Indicates that SAP Analytics Cloud SCIM API version 1 is used. • *2* - Indicates that SAP Analytics Cloud SCIM API version 2 is used. Default value: *1*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Analytic Cloud* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Analytic Cloud system. For more information, see: Manage Transformations [page 2439]

   SAP Analytics Cloud REST API: Managing Users and Teams

   Managing Users and Teams → api/v1/scim

   Managing Users and Teams → api/v1/scim2

   Default transformation for SAP Analytic Cloud SCIM API version 1:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
              "sourcePath": "$.name.givenName",
              "targetPath": "$.name.givenName",
              "optional": true
            },
            {
              "sourcePath": "$.name.middleName",
              "targetPath": "$.name.middleName",
              "optional": true
            },
            {
              "sourcePath": "$.name.familyName",
              "targetPath": "$.name.familyName",
              "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },

                        "function": "concatString",
                        "prefix": "%sac.group.prefix%"
                    }
```

```
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "optional": true,
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:group-roles']",
                "targetPath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:group-roles']",
                "optional": true
            },
            {
                "sourcePath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:group-custom-parameters']",
                "targetPath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:group-custom-parameters']",
                "optional": true
            },
            {   "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.7 SAP Application Server ABAP

Follow this procedure to set up SAP Application Server ABAP (AS ABAP) as a source system.

Prerequisites

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector.
  For more information on how to make a connection to this on-premise system, follow the procedure in Connect to On-Premise Systems [page 2468].
- You have credentials of a technical user with read permissions for AS ABAP, which plays the role of a user data source. Via this user, the Identity Provisioning service will call the ABAP public API in order to execute a number of function modules. These function modules are listed in **step 1** from the procedure below.
- The technical user must have the required RFC and security authorizations, as described in SAP Note 3666721.

> **Note**
>
> If the technical user has insufficient security authorization, no users or roles can be read.

Context

SAP Application Server ABAP (AS ABAP) offers a user store and user administration capabilities for maintaining users and their authorizations for AS ABAP applications. You can configure AS ABAP as a source system for your identity provisioning process, in the following cases:

- Use AS ABAP as a central store for the identity data of your business users.
- Reuse the permission model, implemented in your AS ABAP client, as a permission model for cloud applications. For example, you can provision roles and permission assignments to SAP BTP.

> **Note**
>
> During a provisioning job (*Read* or *Resync*), only active ABAP users are read. That means, users that have been created before the job is started, and whose expiration date is after the end of the job.

Procedure

1. Open the Cloud Connector to add an access control system mapping for **AS ABAP**. This is needed to allow the Identity Provisioning service to access AS ABAP as a back-end system on the intranet. To learn how, see: Configure Access Control (RFC)

Go to *Cloud To On-Premise* > *Access Control* > tab and select protocol *RFC SNC*. Then, expose the following *exact names* as accessible resources:

- `PRGN_ROLE_GETLIST`
- `BAPI_USER_GETLIST`
- `BAPI_USER_GET_DETAIL`
- `BAPI_USER_CREATE1`
- `BAPI_USER_ACTGROUPS_ASSIGN`
- `IDENTITY_MODIFY`
- `BAPI_USER_DELETE`
- `PRGN_ACTIVITY_GROUPS_LOAD_RFC`
- `SUSR_USER_GET_DETAIL_MASS` - available as of `SAP_BASIS 7.58`. For more information, see SAP Note 3631587 and 3677459 .

These are Business Application Programming Interface (BAPI) functional modules designed to perform certain tasks in the SAP AS ABAP system, such as retrieving, creating, updating or deleting user data.

For more information about each function module and its parameters, refer to the documentation provided in the SAP system. Logon to your SAP system and run transaction code **SE37**. In the *Function Builder: Initial Screen*, enter the function name, choose *Display* and then *Functional Module Documentation*.

2. Open SAP BTP cockpit, and in your Identity Provisioning subaccount create a destination for the AS ABAP system. To learn how, see: Create RFC Destinations

   The destination configuration is required by the Identity Provisioning service to find the back-end system to be used for reading data. It also provides the credentials of the technical user, needed for the connection to the ABAP public API.

   Below are the fields you have to fill in the cockpit destination before using an AS ABAP client as a source system.

   > ### Note
   >
   > In the RFC destination, you can set only JCo properties. Properties starting with `abap` are connector specific and must be set in the Identity Provisioning UI.

Field/Property Name	Value
Name	Enter a destination name.
Type	Select *RFC*.
User	Enter the user for AS ABAP. The *User* field corresponds to property `jco.client.user` in the exported RFC destination.
Password	(Credential) Enter the password for the AS ABAP user. The *Password* field corresponds to property `jco.client.passwd` in the exported RFC destination.

Field/Property Name	Value
jco.client.client	The property is configured during destination creation in SAP BTP cockpit. Provide the client to be used in the ABAP system. Valid format is a three-digit number.
Proxy Type	Defines the proxy type of the connection you need to provide for your ABAP system. The value is set during destination creation in SAP BTP cockpit. The proxy type *OnPremise* requires the Cloud Connector to access resources within your on-premise network. Enter: *OnPremise*
Direct Connection	
jco.client.ashost	Provide the virtual host entry that you have configured in the Cloud Connector → *Access Control* configuration. At least one property specifying the target host must be set during destination creation.
jco.client.sysnr	Provide the "system number" of the ABAP system.
Load Balancing Connection	
jco.client.mshost	Represents the message server host to be used. At least one property specifying the target host must be set during destination creation.
jco.client.r3name	Provide the three-character system ID of the ABAP system to be addressed.
jco.client.msserv	Provide the port on which the message server is listening for incoming requests. You can use this property as an alternative to `jco.client.r3name`.
Optional Properties	
`jco.destination.peak_limit`	The value represents the maximum number of active connections that can simultaneously be created for a destination. For example: *10*
`jco.destination.pool_capacity`	The value represents the maximum number of idle connections kept open by the destination. For example: *5*

Field/Property Name	Value
`abap.user.name.filter`	Filters user names by a regular expression. The regex can define any kind of search pattern. For example, `abap.user.name.filter` = **^MAR.*** reads all user names that start with *MAR*, such as **MARK**, **MARTINA**, and so on. **Note** This property has a higher priority over `abap.user.filter`. That means, if you set both properties in a system, the value of **abap.user.name.filter** will be used. However, if the value of `abap.user.name.filter` is empty, then **abap.user.filter**'s value will be used instead.
`abap.role.name.filter`	Filters user roles by a regular expression. The regex can define any kind of search pattern. For example, `abap.role.name.filter` = **^inter.*** reads all roles which start with *inter*, such as **internal**, **internship**, and so on. **Note** This property has a higher priority over `abap.role.filter`. That means, if you set both properties in a system, the value of **abap.role.name.filter** will be used. However, if the value of `abap.role.name.filter` is empty, then **abap.role.filter**'s value will be used instead.
`abap.user.membership.filter`	Filters users by a regular expression, based on their *Role* memberships in AS ABAP. The regex can define any kind of search pattern. For example, `abap.user.membership.filter` = **(?i)^new.*** reads all users who have an assigned role which starts with *new*. This regex is case insensitive, which means the result can be roles starting with **new**, or **New**, or **NEW**, and so on.

Field/Property Name	Value
`abap.user.page.size`	Use this property to configure the number of users to be read from SAP Application Server ABAP at once. If the property is not set, the function module `SUSR_USER_GET_DETAIL_MASS` **cannot** be used, even if it is available on the ABAP server. **Note** The property can be used only when the function module `SUSR_USER_GET_DETAIL_MASS` is exposed as an accessible resource and is present on the ABAP server. Even when these conditions are fulfilled, if the property is not set, the function module **cannot** be used. For more information, see SAP Note 3631587. **Possible values**: Default value: *100* The maximum allowed number is 100.

Note

If connection properties, like `User` and `Password`, are configured both in the destination (SAP BTP cockpit) and on the *Properties* tab (Identity Provisioning User Interface), the values set in the destination are considered with higher priority.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

3. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
4. Add *SAP Application Server ABAP* as a source system. To learn how, see: Add New Systems [page 2415]
5. From the *Destination Name* dropdown, choose the RFC destination you have created in *step 2*.
6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Application Server ABAP* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in AS ABAP. For more information, see Manage Transformations [page 2439].

> ### Note
>
> The value of the **entityIdSourceSystem** attribute stores the unique ID of the entity. Do not delete or change this statement! You can exchange the default attribute **USERNAME** (which is used as a source) with another one, but make sure it is unique.

When AS ABAP is configured as a source system for the Identity Provisioning service, the ABAP public API is used to retrieve the identity data from the AS ABAP system. During the reading process, the JSON data generated by the Identity Provisioning service, is following the structure of the API export parameters list and tables. Every BAPI table is represented as a JSON array and every BAPI structure is represented as a child JSON object.

Default transformation:

['supportedOperations']"
      }
    ]
  }
}
```

7. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Example

How to transform roles, assigned to AS ABAP users, into corporate groups in the Identity Authentication?

The AS ABAP roles are represented as groups in your Identity Authentication tenant. That is, when you configure AS ABAP as a source and Identity Authentication as a target system, the default transformations helps you to use the ABAP roles assignment of the users as source data and to automatically create corporate group assignments for the users in the Identity Authentication. When a user is assigned to one or more AS ABAP roles, the technical names of these roles (their ABAP attribute name is **AGR_NAME**) will become corporate groups value in the Identity Authentication.

1. Transforming source data into the intermediate JSON representation.

The following example demonstrates how the sample roles, read from the AS ABAP system, will become groups in the intermediate JSON data, as a result from the transformation statement:

Data read from AS ABAP user store	Intermediate JSON data

Sample Code
…
"ACTIVITYGROUPS": [
{
"AGR_TEXT": "FICO 03",

}
]
…
	Sample Code
	…
	"groups":[
	{
	"value": "ZFICO_03"
	},
	{
	"value": “ZCASH_01”
	},
	] …

2. The mapping statement in the default transformation, available when the Identity Authentication service is configured as a target system:

Sample Code

```
{
"sourcePath": "$.groups",
"preserveArrayWithSingleElement": true,
"optional": true,
"targetPath": "$.corporateGroups"
}
```

3. The following example demonstrates how the groups from the intermediate JSON are transformed into corporate groups, using the transformation statement:

Intermediate JSON Data	Transformation output result
Sample Code … "groups":[{ "value": "ZFICO_03" }, { "value": “ZCASH_01” },] …	Sample Code … "corporateGroups":[{ "value": "ZFICO_03" }, { "value": “ZCASH_01” },] …

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

ABAP: Supported Languages and Code Pages

1.6.1.8 SAP Ariba Applications

Follow this procedure to set up SAP Ariba Applications as a source system.

Prerequisites

> **Note**
>
> This topic describes customer-managed configurations for the SAP Ariba Applications source system. For SAP-managed configurations, refer to the SAP-Managed SAP Cloud Identity [page 520] documentation.

Next-Generation SCIM API

If you are using the next-generation SCIM API provided by SAP Ariba Applications:

- The Identity Provisioning service must be configured to use the OAuth 2.0 client-credentials flow to obtain access tokens from the Identity Authentication service for calling the SAP Ariba Applications next generation SCIM API. The required dependency must be defined in the configuration of the consumer application. For more information, see Configure Form-Based OAuth Authentication [page 2457].

Current-Generation SCIM API

If you are using the current-generation SCIM API provided by SAP Ariba Applications:

- You have created a client application on SAP Ariba APIs Portal for your integration with Identity Provisioning. This is needed to enable SCIM API for user and group for Ariba Applications. For more information, see Register an Application in SAP Ariba Developer Portal .

  > **Note**
  >
  > If you don't have an SAP Ariba APIs account, go to the SAP Ariba Developer Portal and follow the instructions for sign up. For more information, see Get an SAP Ariba APIs Account.

To find your *realm* name, log in to your SAP Ariba system. It is embedded in your login URL, as illustrated by the following examples:

- SAP Ariba Buyer example: `https://s1.ariba.com/Buyer/Main/ad/loginPage/...&realm=`*mycompany-t*
- SAP Ariba Sourcing example: `http://`*mycompany*`.sourcing.ariba.com/`

- You have enabled the client application for Identity Provisioning on the SAP Ariba Developer Portal.
- You have generated an OAuth secret for your application. For more information, see Generating the OAuth Secret and Base64 Encoded Client ID and Secret.

To set up your SAP Ariba Applications provisioning system, you'll need to map your SAP Ariba application parameters to the corresponding Identity Provisioning properties. The mapping is as follows:

SAP Ariba	Identity Provisioning	Values
SCIM API URL	`URL`	Examples: • US: **https://openapi.ariba.com** • Europe: **https://eu.openapi.ariba.com** • UAE: **https://mn1.openapi.ariba.com** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
SAP Ariba OAuth 2.0 Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token** • UAE: **https://api.mn1.ariba.com/v2/oauth/token** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
OAuth Client ID	`User`	Alphanumeric string Example: **aaaa12345-1111-3333-cccc-1234567890**
OAuth Secret	`Password`	Alphanumeric string Example: **aaaGGG1eee12abcdefGHIJK123lmnopTTT**

SAP Ariba	Identity Provisioning	Values
Application key	`ariba.applications.api.key`	Alphanumeric string Example:**123abc123XYZ000abc123ABC012345**
AN-ID	`ariba.applications.realm.id`	AN<numeric_string> Example: **AN000111222333**

Context

You can read users and groups from SAP Ariba Applications source system and provision them to a target system of your choice.

These source systems can consume either the current-generation SCIM API or the next-generation SCIM API provided by SAP Ariba Applications. Identity Provisioning distinguishes between the two by the API URL pattern (the current SCIM API contains **openapi** in the URL, while the next-generation API does not) and by the `AuthType=Form` property, which must be configured only for the next-generation API.

For more information about the SAP Ariba SCIM API scope of support, see SAP Ariba SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Ariba Applications* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SCIM API URL for your SAP Ariba application (see the **Prerequisites** section). The current-generation SCIM API uses the **openapi** pattern in the URL.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Description & Value
`AuthType`	Enter: *Form* **Relevant for next-generation SCIM API**
`User`	Enter the *Client ID* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`Password`	(Credential) Enter the *Client Secret* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`ariba.applications.api.dependency.name`	This property holds the value of the dependency name used in the configuration of the SAP Ariba Applications consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. **Relevant for next-generation SCIM API**
`ariba.applications.api.key`	(Credential) Enter your application key (see the **Prerequisites** section). **Relevant for current-generation SCIM API**
`ariba.applications.realm.id`	Enter your AN-ID (see the **Prerequisites** section). **Relevant for current-generation SCIM API**
(Optional) `ariba.applications.group.flatten`	This property allows or forbids reading "nested groups" (group structures) from SAP Ariba Applications. If enabled (**true**), group members of type *group* will be ignored during read in order not to be provisioned to target systems that do not support nested groups. Thus, set it to **false** only if you are sure that the target system supports nested groups. Default value: *false* Predefined value (during system creation): *true* Set it to *false* only if you are sure that the target system supports nested groups.

Property Name	Description & Value
(Optional) `ariba.applications.group.children.conversion`	This property allows provisioning of "nested groups" (group structures) of type authorization from SAP Ariba Applications source systems to the Identity Directory of SAP Cloud Identity Services or Identity Authentication (SCIM API version 2) target systems. When enabled (set to true), the members of a given group from SAP Ariba Applications source system will be provisioned to the target system with reversed parent-child relationship. That is, the child groups in the source system become parent groups in the target system, while the original parent group becomes a child group in the target. For more information, see the description of the `children` attribute in Groups. The property is not automatically added during system creation. **Possible values:** • *true* • *false* Default value: *false*

Property Name	Description & Value
`ariba.applications.group.members.page.size`	SAP Ariba Applications has a hardcoded limit of the number of group members returned per request when reading the group SCIM resources. When the Identity Provisioning reads a group, it compares the number of group members with the value configured for `ariba.applications.group.members.page.size`. Depending on the value you defined for `ariba.applications.group.members.paging.enabled`, you can expect the following results: • In case the number of group members equals or exceeds the configured limit and the property `ariba.applications.group.members.paging.enabled` is enabled, the Identity Provisioning will perform full read of all group members via subsequent requests. • In case the number of group members is less than the configured limit or the property `ariba.applications.group.members.paging.enabled` is disabled, the Identity Provisioning will get the returned group members from the target system. Setting the property `ariba.applications.group.members.paging.enabled` allows you to read groups with a large number of group members. For more information, see ariba.applications.group.members.paging.enabled. Default value: *50*
`ariba.applications.group.members.paging.enabled`	This property enables the full read of group members. When it is set to *true*, all groups with members count exceeding the value defined in `ariba.applications.group.members.page.size` will be fully read by the Identity Provisioning via subsequent requests. **Possible values:** • *true* - Full read of group members is enabled. • *false* - Full read of group members is disabled. Default value: *true*

Property Name	Description & Value
`ariba.applications.user.groups.paging.enabled`	SAP Ariba Applications has a hardcoded limitation over the number of user's groups returned per request. This limit is specified by the property `ariba.applications.group.members.page.size`. To trigger a full read of a user with *'groups'* attribute over the configured value, set `ariba.applications.user.groups.paging.enabled` to *true*. **Possible values:** • *true* - the full read of user's groups is enabled. • *false* - the full read of user's groups is disabled. Default value: *true*

Property Name	Description & Value
`ariba.applications.user.groups.page.size`	The number of user groups that SAP Ariba Application returns per request when reading a user. When the Identity Provisioning reads a user, it compares the number groups assigned with the value configured for `ariba.applications.user.groups.page.size`. Depending on the number of groups assigned to the user, you can expect the following results: • If the number of assigned groups is equal or exceeds the configured value, and the `ariba.applications.user.groups.paging.enabled` property is set to *true*, Identity Provisioning will read all user groups in separate requests. For example, if a user has 6 groups assigned and the value of the page size is set to *2*, Identity Provisioning will send 3 requests to read the user groups. • If the number of assigned groups is less than the configured value for `ariba.applications.user.groups.page.size` or the property `ariba.applications.user.groups.paging.enabled` is disabled, the Identity Provisioning will read all user groups via one request. For example, if a user has 2 groups assigned and the value of the page size is set to *6*, Identity Provisioning will read all user groups via one request. Setting the property `ariba.applications.user.groups.paging.enabled` allows you to read users with a large number of groups assigned. For more information, see `ariba.applications.user.groups.paging.enabled`. Default value: *50*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination (property configuration):

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://openapi.ariba.com*

`User`=*aaaa12345-1111-3333-cccc-1234567890*

`Password`=**********

`OAuth2TokenServiceURL`=*https://api.ariba.com/v2/oauth/token*

`ariba.applications.group.flatten`=*true*

`ariba.applications.api.key`=*123abc123XYZ000abc123ABC012345*

`ariba.applications.realm.id`=*AN000111222333*

---

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Applications* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   > ### Note
   >
   > When provisioning from SAP Ariba Applications source system to the Identity Directory of SAP Cloud Identity Services or Identity Authentication (SCIM API version 2) target system, you can preserve the group hierarchy with nested **authorization** groups by setting the `ariba.applications.group.children.conversion` property to *true*.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Applications source system. For more information, see:

   Manage Transformations [page 2439]

   SCIM API for User and Group Master Data

   Default transformation:

['externalLocation']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalLocation']",
        "optional": true
```

```
      },
      {
        "sourcePath":
"$['urn:sap:cloud:scim:schemas:extension:custom:2.0:profile:Group']
['alternativeDisplayNames']",
        "targetPath":
"$['urn:sap:cloud:scim:schemas:extension:custom:2.0:profile:Group']
['alternativeDisplayNames']",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members"
      }
    ]
  }
}
```

5. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Video: Create application and API approval process

1.6.1.9 SAP Ariba Category Management

Follow this procedure to set up SAP Ariba Category Management as a source system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Category Management. For more information, see Creating a SAP Ariba Category Management SCIM Service Instance in Your Subaccount.

> **Note**
>
> This connector has been deprecated as of August 25, 2025, and is no longer needed. Customers with existing configurations should stop running jobs to or from SAP Ariba Category Management provisioning systems.

Context

SAP Ariba Category Management is a cloud-based solution that enables organizations to define and manage purchasing categories and provides actionable market intelligence, category insights, and various tools and templates for developing and operationalizing category strategies that drive business value and performance. This business solution is built on SAP Business Technology Platform (BTP). You can use Identity Provisioning to configure SAP Ariba Category Management as a source system where you can read users from and provision them to a target system.

> **Note**
>
> SAP Ariba Category Management does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Ariba Category Management* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token`
(Optional) `cm.user.filter`	When specified, only those SAP Ariba Category Management users matching the filter expression will be read. For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"* • *emails.value eq "john.doe@example.com" or emails.value eq "john.d@example.com" or emails.value eq "j.doe@example.com"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Category Management* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   SCIM APIs for SAP Ariba Category Management

   Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Ariba Category Management system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   Default transformation:

   Code Syntax

```
{
   "user":{
      "mappings":[
         {
            "sourcePath":"$.id",
            "targetVariable":"entityIdSourceSystem"
         },
         {
            "sourcePath":"$.schemas",
            "targetPath":"$.schemas",
            "preserveArrayWithSingleElement":true
         },
         {
            "sourcePath":"$.userName",
            "targetPath":"$.userName",
            "correlationAttribute":true
         },
         {
```

```
            "sourcePath":"$.externalId",
            "targetPath":"$.externalId",
            "optional":true
         },
         {
            "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
            "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
            "optional": true
         },
         {
            "sourcePath":"$.name.givenName",
            "targetPath":"$.name.givenName",
            "optional":true
         },
         {
            "sourcePath":"$.name.familyName",
            "targetPath":"$.name.familyName",
            "optional":true
         },
         {
            "sourcePath":"$.emails[*].value",
            "targetPath":"$.emails[?(@.value)]",
            "optional":true,
            "preserveArrayWithSingleElement":true
         },
         {
            "sourcePath":"$.emails[?(@.primary== true)].value",
            "optional":true,
            "correlationAttribute":true
         },
         {
            "sourcePath":"$.active",
            "targetPath":"$.active"
         },
         {
            "sourcePath":"$.displayName",
            "targetPath":"$.displayName",
            "optional":true
         }
      ]
   }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

User Replication Setup

1.6.1.10 SAP Ariba Central Invoice Management

Follow this procedure to set up SAP Ariba Central Invoice Management as a source system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Central Invoice Management. This step is automated by the booster *Set Up SAP Ariba Central Invoice Management*. For more information, see Setting Up Invoice Processing with SAP Ariba Central Invoice Management (4N6) –> *Set up Configuration Using Booster in SAP BTP Cockpit*.

Context

SAP Ariba Central Invoice Management is an SAP BTP SaaS application running on SAP BTP, Cloud Foundry environment. This application enables central management of supplier invoices from multiple connected systems, such as SAP S/4HANA Cloud Public Edition systems. You can use Identity Provisioning to configure SAP Ariba Central Invoice Management as a source system where you can read users and groups from and provision them to a target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Ariba Central Invoice Management* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
URL	Enter the URL provided by the service key under the *ips-connector* field without adding the path information. For example: `https://eu10.cim.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token` For example: `https://<my tenant>.authentication.eu10.hana.ondemand.com/oauth/token`
(Optional) `cim.user.filter`	When specified, only those SAP Ariba Central Invoice Management users matching the filter expression will be read. Example: *name.familyName eq "Smith"* and *addresses.country eq "US"*
(Optional) `cim.group.filter`	When specified, only those SAP Ariba Central Invoice Management groups matching the filter expression will be read. Example: *displayName eq "ProjectTeam1"*
(Optional) `cim.group.prefix`	This property distinguishes SAP Ariba Central Invoice Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CIM_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Ariba Central Invoice Management source system and will be provisioned to the target system with the following name pattern: **`CIM_<GroupDisplayName>`**. This way SAP Ariba Central Invoice Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Ariba Central Invoice Management groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Central Invoice Management* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

Manage Transformations [page 2439]

User Management (SCIM) for SAP Ariba Central Invoice Management

Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Ariba Central Invoice Management system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.name.formatted",
        "targetPath": "$.name.formatted",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificPrefix",
```

```
        "targetPath": "$.name.honorificPrefix",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificSuffix",
        "targetPath": "$.name.honorificSuffix",
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "optional": true,
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.userType",
        "targetPath": "$.userType",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$.nickName",
        "targetPath": "$.nickName",
        "optional": true
      },
      {
        "sourcePath": "$.title",
        "targetPath": "$.title",
        "optional": true
      },
      {
        "sourcePath": "$.preferredLanguage",
        "targetPath": "$.preferredLanguage",
        "optional": true
      },
      {
        "sourcePath": "$.timezone",
        "targetPath": "$.timezone",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.groups",
        "targetPath": "$.groups",
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "functions": [
          {
            "condition": "'%cim.group.prefix%' !== 'null'",
            "function": "concatString",
```

```
            "applyOnElements": true,
            "applyOnAttribute": "display",
            "prefix": "%cim.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {  "condition": "'%ips.application.id%' !== 'null'",
         "constant": "%ips.application.id%",
         "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%cim.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%cim.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
```

```
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "optional": true,
        "preserveArrayWithSingleElement": true
      }
    ]
  }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Ariba Central Invoice Management

1.6.1.11 SAP BTP ABAP environment

Follow this procedure to set up SAP BTP ABAP environment as a source system.

Prerequisites

To establish the connection between Identity Provisioning and SAP BTP ABAP environment, you need to set up the communication (user, system and arrangement) on SAP BTP ABAP environment. You have the option to do it either now, as a prerequisite, or while configuring SAP BTP ABAP environment as a source system, as described in step 3.

Context

You can use SAP BTP ABAP environment to read entities from it and provision them to a target system. This scenario supports reading **business users** (Employee), **user assignments**, and **business roles** (which are considered as *groups*).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP BTP ABAP environment* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP BTP ABAP environment and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP BTP ABAP environment source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP BTP ABAP environment backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

      For more information, see Maintain a Communication Arrangement for Inbound Communication

      > ### Note
      >
      > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
      >
      > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP BTP ABAP environment system. You can take the URL from the communication scenario SAP_COM_0193.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`a4c.skip.read.archived`	In the event of archived (disabled) entities in a source SAP BTP ABAP environment system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value
(Optional) `a4c.roles.filter`	Enter OData filtering for reading roles in the SAP BTP ABAP environment system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**
(Optional) `a4c.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP BTP ABAP environment system. The value must be an integer number.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://12345-aaaaa-3333.abap.hana.ondemand.com
User=MyABAPEnvUser
Password=************
ips.date.variable.format=yyyy-MM-dd
a4c.skip.read.archived=true
a4c.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
a4c.roles.page.size=30
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP ABAP environment* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in your SAP BTP ABAP environment. For more information, see:

   Manage Transformations [page 2439]

   Inbound Service: Business User

   Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "($.validityPeriod.startDate <= '${currentDate}') &&
($.validityPeriod.endDate > '${currentDate}')",
    "mappings": [
      {
        "sourcePath": "$.personID",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.personalInformation.firstName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.lastName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.personFullName",
        "targetPath": "$.name.formatted",
        "optional": true
      },
      {
        "sourcePath": "$.user.userName",
        "targetPath": "$.userName",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "constant": true,
        "targetPath": "$.active"
      },
      {
        "condition": "$.user.lockedIndicator == 'true'",
        "constant": false,
        "targetPath": "$.active",
        "optional": true
      },
// The following condition states that if a business user is outside its
validity period, it will be set as inactive.
// That means, this user will not be able to log into the SAP BTP ABAP
environment system.
      {
        "condition": "($.user.validityPeriod.startDate > '${currentDate}')
|| ('${currentDate}' > $.user.validityPeriod.endDate)",
        "constant": false,
        "optional": true,
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.workplaceInformation.emailAddress",
        "targetPath": "$.emails[0].value",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.user.logonLanguageCode",
        "optional": true,
```

```
        "targetPath": "$.locale"
      },
      {
        "sourcePath": "$.PersonExternalID",
        "optional": true,
        "correlationAttribute": true
      },
// The Identity Provisioning reads both users and user assignments from
SAP BTP ABAP environment.

      },
      {
        "constant": "readWrite",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

User Provisioning in SAP BTP ABAP environment

1.6.1.12 SAP BTP Account Members (Neo)

Follow this procedure to set up your SAP Business Technology Platform as a source system, from which you can read and manage members in your Neo account.

Prerequisites

You have created a new Platform API OAuth client, with API *Account Member Management* and scopes *Manage Account Members* and *Read Account Members*.

Save the *Client ID* and *Client Secret* as you'll need them when you configure your source system. Make sure you save the client secret as you cannot retrieve it later.

For more information, see Create a Platform API Client.

Context

The Identity Provisioning service helps companies to automatically manage the user-to-platform roles assignments for SAP Business Technology Platform subaccounts. For this scenario, as a source system are used SAP BTP subaccounts. The target system can be a solution supported by the Identity Provisioning service with write access for user and group artifacts.

This provisioning scenario is based on the Platform Authorization Management API of SAP BTP. For more information, see Platform Authorization Management API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP BTP Account Members (Neo)* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/platform/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_BTP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Account Members (Neo)* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Using the default transformation, all users and platform roles available in the SAP Business Technology Platform source system will be created as users and groups in the chosen target system.

   You can change the default transformation mapping rules to reflect the data to be written in your source system. For more information, see:

   Manage Transformations [page 2439]

   SAP BTP: Authorization Management API

   Default transformation:

   Code Syntax

```
{
  "user": {

        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[*].type"
      }
    ]
  }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

What is SAP BTP

1.6.1.13 SAP BTP Platform Members (Cloud Foundry)

Follow this procedure to set up the SAP BTP Platform Members (Cloud Foundry) as a source system.

Prerequisites

- You have a global account in SAP BTP with at least one multi-environment subaccount with enabled Cloud Foundry environment.

- You have established trust between your SAP Cloud Identity Services tenant as custom identity provider for platform users and your global account(s) containing these subaccounts. For more information, see Establish Trust and Federation of Custom Identity Providers for Platform Users.
- You have created a CF provisioning user (which is a regular user of type *Employee* in the local identity directory of your SAP Cloud Identity Services tenant) that will be used for provisioning. Give this user an email address with the following pattern `cf-user-provisioning-<origin_key>@sap.invalid`, where `<origin_key>` is the origin key of the trust configuration for BTP platform users which points to your SAP Cloud Identity Services tenant. You have set an initial password for the user and marked its email address as *verified*. For more information, see Create a New User and List and Edit User Details.

  > **Note**
  >
  > The password lifetime for the CF provisioning user depends on the password policy set for the *SAP Business Technology Platform* application in the administration console of SAP Cloud Identity Services. For more information, see Set a Password Policy for an Application.

- You have activated the account of the CF provisioning user by opening the *Profile Page* of SAP Cloud Identity Services, in a separate browser session, and changing its initial password. The URL has the following pattern: `https://<tenant ID>.accounts.ondemand.com` or `https://<tenant ID>.accounts.cloud.sap`
- You have created the group *cf-user-provisioning* in your SAP Cloud Identity Services tenant and added the CF provisioning user to it. For more information, see Create a New Group and Add Users to a Group.
- You have added the CF provisioning user as org member with role **Org Manager** to each Cloud Foundry organization where you want to provision users, in the SAP BTP cockpit. For more information, see Add Org Members and About Roles in the Cloud Foundry Environment.

Context

The Cloud Foundry environment enables you to create polyglot cloud applications in Cloud Foundry. It contains the SAP BTP, Cloud Foundry runtime service, which is based on the open-source application platform managed by the Cloud Foundry Foundation. For more information, see Cloud Foundry Environment.

When you enable the Cloud Foundry environment in your subaccount, the system automatically creates a Cloud Foundry organization for you. You can add platform users as org members and space members and assign roles to grant these users platform access. For more information, see Valid role types .

In this scenario, your SAP Cloud Identity Services tenant acts as your identity provider and SAP BTP acts as your service provider. Identity Provisioning in between provides the SAP BTP Platform Members (Cloud Foundry) connector to replicate the org and space members with their role assignments from the identity provider to the local user storage of SAP BTP. For more information, see SAP BTP Integration Scenario.

SAP BTP Platform Members (Cloud Foundry) connector manages org and space members, as well as their role assignments, in the Cloud Foundry environment of a multi-environment subaccount, where a **single** SAP Cloud Identity Services tenant acts as custom identity provider. We recommend that you use the Identity Provisioning service enabled in this SAP Cloud Identity Services tenant.

Follow the steps below to create SAP BTP Platform Members (Cloud Foundry) as a source system to read users (org members and space members), roles (organization and space), and role assignments from your Cloud Foundry environment, which can then be provisioned to target systems of your choice. In SAP BTP Platform Members (Cloud Foundry), groups correspond to roles in particular Cloud Foundry orgs or spaces, thus group

members are user assignments of a role in a specific Cloud Foundry org or space. Group names must follow a defined pattern, explained below, to ensure the correct mapping and provisioning of users and their role assignments to the relevant Cloud Foundry organization or space.

> **Note**
>
> The attribute *name*, defined within the *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group* schema, is used to map the users and user assignments of a role to the relevant Cloud Foundry organization or space. The group names follow the respective patterns:
>
> - organization group name: `<org_ID> <org_role>`
> - space group name: `<org_ID> <space_ID> <space_role>`, where `space_ID` can be retrieved using the Cloud Foundry Command Line Interface by executing the command **`cf space --guid`**.
>
> Whereas the group display names adhere to the following patterns:
>
> - organization group display name: `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<org_role>`
> - space group display name: `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<space_name>:<space_role>`

> **Note**
>
> In case you have Cloud Foundry environment enabled in multiple Cloud Foundry landscapes or more than one SAP Cloud Identity Services tenants, you must configure a separate SAP BTP Platform Members (Cloud Foundry) connector for each of them.

The source system consumes `User Account and Authentication API` and `Cloud Foundry V3 API` provided by Cloud Foundry.

Procedure

1. To enable provisioning of platform users and user role assignments to and from Cloud Foundry environment, create a Support Ticket on component `BC-CP-CF-SEC-IAM`.

   Specify your SAP Cloud Identity Services tenant ID and the origin key of the trust configuration for BTP platform users which points to your SAP Cloud Identity Services tenant. You can find the origin key value in the SAP BTP cockpit. Go to your SAP BTP subaccount, choose *Trust Configuration* and see the value under *Origin Key* for the relevant *Custom Identity Provider for Platform Users*.

2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *SAP BTP Platform Members (Cloud Foundry)* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the `email` of the CF provisioning user (see **Prerequisites**).
`Password`	(Credential) Enter the password for the CF provisioning user (see **Prerequisites**).
`btp.cf.pm.origin`	Enter the origin key of your SAP Cloud Identity Services tenant (see **Step 1**). The value of this property is a string, which always ends with the suffix *-platform*. It will be used as the *origin* attribute in the system transformation.

Property Name	Description & Value
`btp.cf.pm.landscape`	Enter the *technical key* or the *host name* of the landscape in which your multi-environment subaccount with enabled Cloud Foundry environment is located. The technical key is available only for the SAP BTP Cloud Foundry regions. For more information, see Regions and API Endpoints Available for the Cloud Foundry Environment. Please note that when the technical key contains an extension index, the correct value is displayed in the *API Endpoint* column instead of the *Technical Key* column of the table. This is an example of a *technical key*: **`cf-eu10-002`**, corresponding to the API endpoint `api.cf.eu10-002.hana.ondemand.com` and host name `cf.eu10-002.hana.ondemand.com` The host name of the landscape can be found by looking up the *API Endpoint* field in the *Overview* tab of your *Cloud Foundry Environment* on subaccount level of the SAP BTP cockpit. The API endpoint has the following format: `https://api.<landscape-hostname>` **Note** If your provisioning job finishes with error *'Name or service not known'*, the value used for technical key is not correct. In that case you can use the host name of the landscape instead.
(Optional) `btp.cf.pm.user.filter`	When specified, only those SAP BTP Platform Members (Cloud Foundry) users matching the filter expression will be read. For example: *userName eq "SmithJ"*

Property Name	Description & Value
(Optional) `btp.cf.pm.group.prefix`	This property distinguishes SAP BTP Platform Members (Cloud Foundry) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`BTP_CF_PM_`** When set in the source system, the prefix will be prepended to the name of the groups that are read from the SAP BTP Platform Members (Cloud Foundry) source system and will be provisioned to the target system with the following name pattern: **`BTP_CF_PM_<GroupDisplayName>`**. This way SAP BTP Platform Members (Cloud Foundry) groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP BTP Platform Members (Cloud Foundry) groups will be read and provisioned to the target system with their actual display names.
(Optional) `ips.trace.failed.entity.content`	If a provisioning job repeatedly fails and you need problem investigation, you can enable logging and tracing for the personal and sensitive data of your provisioned entities. To do this, set this property to *true*. For more information, see List of Properties [page 80].

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Platform Members (Cloud Foundry)* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP Platform Members (Cloud Foundry) system. For more information, see:

   Manage Transformations [page 2439]

   Cloud Foundry V3 API

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from a SAP BTP Platform Members (Cloud Foundry) entity to the intermediate Identity Provisioning representation.
   - **User offboarding** – If a user or a user assignment of a role has been deleted from the SAP BTP Platform Members (Cloud Foundry), this change is recognized, and the user/user assignment of a role is deleted from the target system too.

⚠ Caution

Keep in mind that when you add or delete users and user role assignments in SAP BTP Platform Members (Cloud Foundry), the operations order must adhere to the Cloud Foundry Environment hierarchy. In this case, you can expect the following behavior:

- When adding a user as space member, it must already be present as member of the relevant organization with assigned role **Org User**. When deleting an org member, it should be first removed from the spaces of the relevant organization. In case you end up with erroneous entity structure, you can manually add or delete users via the administration console for SAP Cloud Identity Services.
- When adding user role assignments, you should first add the org roles and afterwards proceed with the space roles. Also, when deleting user role assignments, you should first delete the space roles and then proceed with the org roles. If this condition is not fulfilled the job will finish with error. In that case, you can rerun the job until it finishes successfully.

Default transformation:

```
        "optional": true
      },
      {
        "sourcePath": "$.verified",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "sourcePath": "$.origin",
        "targetPath": "$.origin",
        "optional": true
      },
      {
        "sourcePath": "$.zoneId",
        "targetPath": "$.zoneId",
        "optional": true
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetPath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.id",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:Group"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%btp.cf.pm.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%btp.cf.pm.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "constant": "authorization",
```

```
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {
        "constant": "userOnlyMembership",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      }
    ]
  }
}
```

6. Now, add a target system to which to provision users and user assignment of a role. For example: Local Identity Directory [page 957]
7. (Optional) Run a *Simulate* and/or a *Validate* job before you run the actual provisioning job to verify that Identity Provisioning configurations produce the desired result in the target systems. For more information, see Simulate Provisioning Jobs [page 2477] and Validate Provisioning Jobs [page 2478].

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP BTP Integration Scenario

1.6.1.14 SAP BTP Java/HTML5 apps (Neo)

Follow this procedure to set up SAP Business Technology Platform as a source system, from which you can read user-to-groups assignments for Java/HTML5 applications that run on SAP BTP, Neo environment.

Prerequisites

You have created a new Platform API OAuth client, with *Authorization Management* scopes. Save the *Client ID* and *Client Secret* as you'll need them when you configure your source system. Make sure you save the client secret as you cannot retrieve it later.

For more information, see Create a Platform API Client.

Context

The Identity Provisioning service helps companies to automatically manage the user-to-groups assignments for Java/HTML5 applications running on SAP BTP, Neo environment. For this scenario, SAP BTP is the source system. The target system can be a solution supported by the Identity Provisioning service with write access for user and group artifacts.

This provisioning scenario is based on the Authorization Management REST API of the SAP Business Technology Platform. For more information, see Using the Authorization Management REST API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP BTP Java/HTML5 apps (Neo)* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_BTP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*
`hcp.application.names`	Enter a comma-separated list of application names. That could be applications deployed on your account, or applications for which your account has subscribed. The property returns the roles assigned to these applications. Use the following format (no spaces): *<app_name1>,<app_name2>,<provider_subaccount>:<provider_app>* **⚠ Caution** You must not leave this property with an empty value.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Java/HTML5 apps (Neo)* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Using the default transformation, all groups and their members (with roles) available in the SAP Business Technology Platform source system will be created as groups and respective members (with roles) in the chosen target system.

   You can change the default transformation mapping rules to reflect the data to be written in the target system. For more information, see:

   Manage Transformations [page 2439]

   SAP BTP: Authorization Management API

   Default transformation:

   {·} Code Syntax

   ```
   // To read the roles assigned to your applications, add property
   hcp.application.names to your system configuration.
   {
     "role": {
       "mappings": [
         {
   ```

```
        "targetPath": "$",
        "sourcePath": "$"
      },
      {
        "targetVariable": "entityIdSourceSystem",
        "constant": "-",
        "functions": [
          {
            "type": "concatString",
            "prefix": "$.applicationName",
            "suffix": "$.name"
          }
        ]
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "targetPath": "$.id",
        "sourcePath": "$.name"
      },
      {
        "targetVariable": "entityIdSourceSystem",
        "sourcePath": "$.name"
      },
      {
        "targetPath": "$.displayName",
           "sourcePath": "$.name",
        "functions": [
          {
            "condition": "'%hcp.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%hcp.group.prefix%"
          }
        ]
      },
      {
        "targetPath": "$.schemas[0]",
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group"
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members[?(@.value)]",
        "optional": true
      },
      {
        "constant": "User",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members[*].type",
        "optional": true
      }
    ]
  },
  "user": {
    "mappings": [
      {
        "sourcePath": "$.name",
        "targetPath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "targetPath": "$.displayName",
        "sourcePath": "$.name"
      },
      {
        "targetPath": "$.userName",
```

```
        "sourcePath": "$.name",
        "correlationAttribute": true
      },
      {
        "targetPath": "$.schemas[0]",
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User"
      },
      {
        "sourcePath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.groups[?(@.value)]",
        "optional": true
      },
      {
        "constant": "direct",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.groups[*].type",
        "optional": true
      }
    ]
  }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

What is SAP BTP

1.6.1.15 SAP BTP XS Advanced UAA (Cloud Foundry)

Follow this procedure to set up the SAP BTP XS Advanced UAA (running on SAP BTP, Cloud Foundry environment) as a source system.

Prerequisites

You have created credentials to call the REST APIs of the SAP Authorization and Trust Management service on global account, subaccount, or directory level. For more information, see: Get Access to the APIs and btp create security/api-credential.

Context

The SAP BTP XS Advanced UAA connector enables you to read platform users, business users, groups and group assignments from the local user stores of global accounts, directories, and multi-environment subaccounts on SAP BTP. These users and groups (considered role collections in SAP BTP), can then be provisioned to target systems of your choice.

Create a separate source system for each global account, subaccount and directory, and configure the respective credentials and connectivity properties. Depending from where you want to read your entities, you need to:

- Create a source system for the global account to provision **platform users** and groups.
- Create a source system for the directory to provision **platform users** and groups.
- Create a source system for the subaccount to provision **platform users**, **business users** and groups.

> **Note**
>
> Reading of platform users as **org members** and **space members** requires the usage of a different connector: SAP BTP Platform Members (Cloud Foundry). For more information, see SAP BTP Platform Members (Cloud Foundry) [page 1034].

Follow the steps below to create SAP BTP XS Advanced UAA as a source system to read SAP BTP users and groups from global accounts, directories, and multi-environment subaccounts on SAP BTP.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP BTP XS Advanced UAA (Cloud Foundry)* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the API URL in the following format: `https://api.authentication.<region>.hana.ondemand.com` or For more information, see Call an API.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service in the following format: • `https://<global_account_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or • `https://<subaccount_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or • `https://<directory_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or For more information, see Call an API.
`User`	Enter the respective OAuth client ID that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.
`Password`	(Credential) Enter the respective OAuth client secret that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.
`xsuaa.origin.filter.enabled`	This flag property depends on `xsuaa.origin`. Possible values: **true** or **false** • If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `xsuaa.origin`. • If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. • If set to *true* but the `xsuaa.origin` property is missing, the provisioning job will fail.

Property Name	Description & Value
`xsuaa.origin`	Enter the Origin Key of your identity provider. This is needed only when the `xsuaa.origin.filter.enabled` property is set to *true*. • Identity provider for platform users: In the SAP BTP cockpit, go to your global account (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for platform users. This origin key always ends with `-platform`. • Identity provider for business users: In the SAP BTP cockpit, go to your subaccount (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for business (application) users. For example: sap.custom **Note** If multiple origins are configured, a user will be read multiple times - once per origin - but only one user will be created in the target. For more information, see Configure Single and Multiple Origins [page 693]
`xsuaa.group.prefix`	This property distinguishes SAP BTP XS Advanced UAA (Cloud Foundry) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **XSUAA_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **XSUAA_** prefix in their display name will be provisioned to SAP BTP XS Advanced UAA (Cloud Foundry). Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP BTP XS Advanced UAA (Cloud Foundry).

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://api.authentication.eu10.hana.ondemand.com
OAuth2TokenServiceURL=https://myaccount.authentication.eu10.hana.ondemand.com/oauth/token
User=sb-full-access!a76125
Password=************
xsuaa.origin=sap.custom
xsuaa.origin.filter.enabled=true
```

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Advanced UAA* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from an SAP BTP XS Advanced UAA entity to the intermediate Identity Provisioning representation.
   - **User offboarding** – If a user or group has been deleted from the SAP BTP XS Advanced UAA, this change is recognized and the user/group is deleted in the target system too.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP XS Advanced UAA system. For more information, see Manage Transformations [page 2439] and the API documentation.

   - User Management (System for Cross-domain Identity Management (SCIM))- SCIM groups - role collections
   - User Management (System for Cross-domain Identity Management (SCIM)) - SCIM users - shadow users

   Default transformation:

   Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath":"$.name.givenName",
```

```
        "targetPath":"$.name.givenName",
        "optional":true
      },
      {
        "sourcePath":"$.name.familyName",
        "targetPath":"$.name.familyName",
        "optional":true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.groups",
        "targetPath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "functions": [
          {
            "condition": "'%xsuaa.group.prefix%' !== 'null'",
            "function": "concatString",
            "applyOnElements": true,
            "applyOnAttribute": "display",
            "prefix": "%xsuaa.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.verified",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.origin",
        "targetPath": "$.origin",
        "optional": true
      },
      {
        "sourcePath": "$.zoneId",
        "targetPath": "$.zoneId",
        "optional": true
      }
    ]
  },
  "group": {
    "mappings": [
      {
```

```
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%xsuaa.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%xsuaa.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "sourcePath": "$.description",
        "targetPath": "$.description",
        "optional": true
      },
      {
        "sourcePath": "$.zoneId",
        "targetPath": "$.zoneId",
        "optional": true
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "constant": "authorization",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      }
    ]
  }
}
```

5. Add a target system to which to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

btp CLI Command Reference
SAP BTP Integration Scenario

1.6.1.15.1 Configure Single and Multiple Origins

Configure and provision users with single or multiple origins in SAP BTP XS Advanced UAA (Cloud Foundry) source system.

Overview

An origin tells you which is the identity provider of a user in SAP BTP XS Advanced UAA (Cloud Foundry). It is defined in the trust configuration in the SAP BTP cockpit under *Security* > *Trust Configuration* > *Origin Key*.

The origin itself is not a concept of Identity Provisioning. The role of the service is to ensure that you can read and provision users with their identity providers. Once you find the identity provider in the Origin Key, you need to set it in the `xsuaa.origin` property. You can configure it in source, target and proxy SAP BTP XS Advanced UAA (Cloud Foundry) systems. Both single and multiple values are supported. The value is a string that usually specifies the name of the identity provider or its location.

For example: `xsuaa.origin=`*ldap* and `xsuaa.origin=` *ldap;myaccount-xsuaa.accounts.ondemand.com*, where the ";" (semicolon) is the only supported delimiter.

Provisioning Users with Single Origin

You want to provision a user with a single origin from SAP BTP XS Advanced UAA (Cloud Foundry) source system to a given target system.

1. On the *Properties* tab of the source system, set the `xsuaa.origin.filter.enabled` property to *true*. This is a prerequisite for enabling the `xsuaa.origin` property in source systems.
2. Enter the value for the `xsuaa.origin` property, for example: *idp1*.
   The value of this property acts like a filter as only users with the values specified there are read.

3. Run a provisioning job.

As a result, one user entry with single origin is read and created in the target system.

Provisioning Users with Multiple Origins

You want to provision a user with multiple origins from SAP BTP XS Advanced UAA (Cloud Foundry) source system to a given target system.

1. On the *Properties* tab of the source system, set the `xsuaa.origin.filter.enabled` property to *true*.
   This is a prerequisite for enabling the `xsuaa.origin` property in source systems.
2. Enter multiple values for the `xsuaa.origin` property, for example: *idp1;idp2*.
   The value of this property acts like a filter as only users with the values specified there are read.
3. Set the `ips.delete.existedbefore.entities` property to *true* on the target system.
   This is needed before you run the provisioning job. It will ensure that previously existed users in the target system will be deleted if they were deleted in the source. For more information, see Manage Deleted Entities [page 2463]
4. Run a provisioning job.

As a result, two user entries for one and the same user are read. Only one user is created in the target system, because it does not support the origin concept and recognizes both user entries as one user. The job logs show that two users are read, one is created, and one is updated on the target system. A deletion of one of the origins in the source system would result in the following statistics: one user is read and one user is updated.

> **Note**
>
> Multiple origins are not supported in provisioning scenarios between SAP BTP XS Advanced UAA (Cloud Foundry) source system and SAP BTP XS Advanced UAA (Cloud Foundry) target system.

1.6.1.16 SAP Build Work Zone, advanced edition

Follow this procedure to set up SAP Build Work Zone, advanced edition as a source system.

Prerequisites

You have OAuth credentials for SAP Build Work Zone, advanced edition. To learn how, see SAP Build Work Zone, advanced edition: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a source SAP Build Work Zone, advanced edition system to read users and groups.

These source systems consume SCIM 2.0 API provided by SAP Build Work Zone, advanced edition.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Build Work Zone, advanced edition* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Build Work Zone, advanced edition and configure the authentication method (basic or OAuth certificate-based).

   > ### Note
   >
   > We recommend that you use OAuth certificate-based authentication in the regions where it is supported by SAP Build Work Zone, advanced edition. This authentication method is supported for subaccounts created on the recommended data centers for new customers according to the SAP Build Work Zone, advanced edition documentation.

   a. In your newly added SAP Build Work Zone, advanced edition source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in the SAP Build Work Zone, advanced edition Admin Console and are relevant for certificate-based authentication only.

   b. Login to the SAP Build Work Zone, advanced edition Admin Console and execute substep *2. f. iii. Use X.509 Certificate-Based Authentication* from *Step 3: Configure the Identity Authentication service and the Identity Provisioning service* in Option 1: Create a new tenant .
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
URL	Enter the URL related to your SAP Build Work Zone, advanced edition system, in format: **`https://<account><sap_wz_domain>.workzone.ondemand.com`** For example: *https://mytenant.mydomain123.workzone.ondemand.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*

Property Name	Description & Value
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the OAuth client key, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Enter the OAuth client secret, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Build Work Zone, advanced edition instance, based on the configured authentication method: • *BasicAuthentication* - **`https://<account><sap_wz_domain>.workzone.ondemand.com/api/v1/auth/token`** For example: *https://myaccountmydomain123.workzone.ondemand.com/api/v1/auth/token* • *ClientCertificateAuthentication* - **`https://<company_uuid>.api-<region_host>.dws.workzone.ondemand.com/api/v2/auth/token`** **Note** The `api-` prefix before `<region_host>` is necessary for using *ClientCertificateAuthentication* authentication. For example: *https://mycompanyuuid123.api-eu-20.dws.workzone.ondemand.com/api/v2/auth/token*
`client_id`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth Client id used for access token retrieval.
Optional Properties	
(Optional) `workzone.group.filter`	Enter a SCIM-based search criteria for filtering groups. Example: **displayName eq "Project123"**
(Optional) `workzone.user.filter`	Enter a SCIM-based search criteria for filtering users. Example: **userName eq "SmithJ"**

Property Name	Description & Value
(Optional) `ips.failed.request.retry.attempts`	Predefined value: *2*
(Optional) `ips.failed.request.retry.attempts.interval`	Predefined value: *30*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Build Work Zone, advanced edition* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Build Work Zone, advanced edition system. For more information, see:

   Manage Transformations [page 2439]

   SAP Build Work Zone SCIM API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "type": "remove",
                "targetPath": "$.id"
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            },
            {
```

```
                "sourcePath":"$.name.givenName",
                "targetPath":"$.name.givenName",
                "optional":true
            },
            {
                "sourcePath":"$.name.familyName",
                "targetPath":"$.name.familyName",
                "optional":true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",

'null'",
                        "prefix": "%workzone.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
                "optional": true,
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']"
            },
            {
                "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['description']",
                "optional": true,
                "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['description']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
            },
            {
                "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            }
        ]
```

```
    }
}
```

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.17 SAP Business Network

Follow this procedure to set up SAP Business Network as a source system.

Context

> **Note**
>
> Currently, the SAP Business Network connector cannot be used by customers due to API access constraints. SAP is working on resolving these constraints to make the connector fully operational and accessible.

SAP Business Network, formerly known as Ariba Network, is a cloud-based offering that makes it possible for buyers and suppliers to collaborate on transactions, strengthen their relationships, and discover new business opportunities.

You can use Identity Provisioning to configure SAP Business Network as a source system where you can read users and groups and provision them to target systems of your choice.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Business Network* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the SAP Business Network API URL.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Business Network system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Business Network system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.
`bn.api.key`	An API Key represents the unique key that identifies a particular application as a legitimate consumer of an API.
`bn.realm.id`	The realm name is part of the URL you use to access SAP Business Network.
(Optional) `bn.user.filter`	When specified, only those SAP Business Network users matching the filter expression will be read. For example: • *userName eq "Julie Armstrong"* • *userName sw "J"* • *emails eq "julie.armstrong@example.com"* For more information, see List of Properties [page 80]
(Optional) `bn.group.filter`	When specified, only those SAP Business Network groups matching the filter expression will be read. For example: *displayName eq "Employees"* For more information, see List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Business Network* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Business Network system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
        "optional": true
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:sap.business.network:2.0:User']
['userStatus']",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:sap.business.network:2.0:User']
['userStatus']",
        "optional": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "correlationAttribute": true,
        "optional": true
      },
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
```

```
      "sourcePath": "$.name.familyName",
      "targetPath": "$.name.familyName"
    },
    {
      "sourcePath": "$.name.formatted",
      "targetPath": "$.name.formattedName",
      "optional": true
    },
    {
      "sourcePath": "$.name.honorificPrefix",
      "targetPath": "$.name.honorificPrefix",
      "optional": true
    },
    {
      "sourcePath": "$.name.honorificSuffix",
      "targetPath": "$.name.honorificSuffix",
      "optional": true
    },
    {
      "sourcePath": "$.displayName",
      "targetPath": "$.displayName",
      "optional": true
    },
    {
      "sourcePath": "$.emails",
      "targetPath": "$.emails",
      "preserveArrayWithSingleElement": true
    },
    {
      "sourcePath": "$.emails[0].value",
      "correlationAttribute": true
    },
    {
      "sourcePath": "$.active",
      "targetPath": "$.active"
    },
    {
      "sourcePath": "$.preferredLanguage",
      "targetPath": "$.preferredLanguage",
      "optional": true
    },
    {
      "sourcePath": "$.addresses",
      "targetPath": "$.addresses",

        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      }
    ]
  }
}
```

5. Add a target system to provision users and groups to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Business Network

1.6.1.18 SAP Central Business Configuration

Follow this procedure to set up SAP Central Business Configuration (in short, CBC) as a source system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the API of SAP Central Business Configuration for reading user and group information.

Context

Create a CBC source system to read users, groups, and group members from it.

> **Note**
>
> Reading users is skipped by default. To enable it, go to the transformation and set the *"ignore": true* statement to **false**.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Central Business Configuration* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your CBC system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Specify the technical user for your CBC system.
`Password`	(Credential) Specify the password for your technical user.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://mycbcaccount.authentication.us2.hana.ondemand.com/oauth/token**
(Optional) `cbc.user.filter`	When specified, only those CBC users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"** **Note** Using this property makes sense only if you have set the *"ignore": true* statement to **false**.
(Optional) `cbc.group.filter`	When specified, only those CBC groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Central Business Configuration* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your CBC system. For more information, see Manage Transformations [page 2439].

   Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source CBC system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   Note

   Provisioning of user's group assignments from an SAP Central Business Configuration source system to a given target system require that users already exist in the target system. These users should be initially created by a previously executed job from that source system.

   Afterwards, the provisioning of user assignments can be triggered by running a read or resync job.

   Default transformation:

   Code Syntax

   ```
   {
       "group": {
   ```

```
        "mappings": [
            {
                "sourcePath": "$.schema",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schema"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",

                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.userType",
                "optional": true,
                "targetPath": "$.userType"
            },
            {
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.groups",
                "functions": [
                    {
                        "condition": "'%cbc.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%cbc.group.prefix%"
                    }
                ]
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Central Business Configuration – Collection

1.6.1.19 SAP Commerce Cloud

Follow this procedure to set up SAP Commerce Cloud as a source system.

Prerequisites

- In SAP Commerce Cloud, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Configuring OAuth Client.

Context

SAP Commerce Cloud is a highly flexible and modular platform for delivering modern customer experiences. It provides a standardized, automated, end-to-end solution that allows your projects to release code from repository to cloud.

You can use Identity Provisioning to configure SAP Commerce Cloud as a source system to read users and groups. These source systems consume SCIM 2.0 API provided by SAP Commerce Cloud. For more information, see Commerce Cloud SCIM Web Services API Documentation.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Commerce Cloud* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Commerce Cloud system. The URL follows the pattern: `https://backoffice.<tenant>. model-t.cc.commerce.ondemand.com` You can find the correct URL in the *Environments* section of SAP Cloud Portal.
`ProxyType`	Enter: *Internet*

Property Name	Description & Value
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Commerce Cloud.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Commerce Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Commerce Cloud instance.
(Optional) `cc.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails.value`**, and **`externalId`**, according to the API syntax of SAP Commerce Cloud. For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators.
(Optional) `cc.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *displayName eq "ProjectTeam1" or "Students2018"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Commerce Cloud* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Commerce Cloud system. For more information, see:

   Manage Transformations [page 2439]

   Commerce Cloud SCIM Web Services API Documentation

> ### Note
>
> When configuring SAP Commerce Cloud as a source system, note that there may be mismatches between optional and required user attributes in the given target systems. For example, the email is an optional attribute in SAP Commerce Cloud but a required one in Identity Authentication. In such cases, you need to review and adapt your source and/or target system transformations and configurations to reflect your needs.

> ### Note
>
> Users that are created in SAP Commerce Cloud through the UI, don't have an ID and a username. As the ID is a mandatory attribute by SCIM specification, provisioning of those users to target systems will fail.
>
> To solve this, create the users in SAP Commerce Cloud through API or implement ImpEx (import and export) for user ID provisioning, as described in Configuring SAP Commerce Cloud.

Default transformation:

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                   {
                        "function": "concatString",
                        "condition": "'%cc.group.prefix%' !== 'null'",
                        "prefix": "%cc.group.prefix%"
                   }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members"
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from:Target Systems [page 936].

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Cloud Identity Services Integration Architecture → cloudscimwebservices extension

1.6.1.20 SAP Concur

Follow this procedure to set up SAP Concur as a source system.

Prerequisites

- You are using User v1 API, Identity v4 API or SCIM v4 API.

  > **Note**
  >
  > The **User v1 API** has been decommissioned. For more information, see Concur User API Decommission.

- Your SAP Concur admin user has obtained a *Company Request Token* and a *Company UUID* from the SAP Concur Company Request Token self-service tool.
  For more information, see SAP Concur Company Request Token.

Context

Companies that use SAP Concur for managing and controlling travel expenses, invoices and other can use Identity Provisioning service to automate the identity and access management for the SAP Concur solution. This service allows you to read identity data from SAP Concur and provision it to a target system of your choice (corporate user stores or SAP cloud user stores).

SAP Concur provides different APIs for integration with Identity Provisioning, resulting in different connector versions. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `concur.api.version` property controls which API you use.

- When the value is set to **3**, the SCIM v4 API is used. It supports reading of users and groups.
  By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced. The default version is the latest released connector version at the time the system is created.
- When the value is set to **2**, the Identity v4 API is used. This applies to systems created between December 8, 2021, and December 1, 2025. Identity v4 API supports provisioning of users with the `userUUID` attribute, which is generated by Identity Authentication at user creation.
- When the value is set to **1**, or the property is not defined, the User v1 API is used. This applies to systems created before versioning was introduced on December 8, 2021. Version 1 is deprecated.

For more information on how to update to the connector version you need, see: Update Connector Version [page 2424].

To create SAP Concur as a source system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Concur* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Connector Version 1 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	For EU2 data center, enter: **`eu2.concursolutions.com`** For US2 data center, enter: **`www.concursolutions.com`**
`ProxyType`	Enter: **`Internet`**
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *1* to use the User v1 API.
`Authentication`	Enter: *BasicAuthentication*
`User`	Deprecated property. Do not use.
`Password`	Deprecated property. Do not use.
`X-ConsumerKey`	Deprecated property. Do not use.
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`

Property Name	Description & Value
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. **→ Remember** The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com

Connector Version 2 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*

Property Name	Description & Value
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *2* to use the Identity v4 API. This was the default value for systems created between December 8, 2021, and December 1, 2025.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.

Property Name	Description & Value
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com
(Optional) `concur.user.filter`	When specified, only those users matching the filter expression will be read. For example: • *userName* eq "johnsmith@example.com" As the userName must be unique in SAP Concur, this filter returns only the user matching this userName. • *companyId* eq "aa067ada-71a9-4f57-8e98-9300b1c3171d" This filter returns all users in the company with this companyId.

Connector Version 3 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`

Property Name	Description & Value
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *3* to use the SCIM v4 API. By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com

Property Name	Description & Value
(Optional) `concur.user.filter`	When specified, only those users matching the filter expression will be read. For example: • *userName* eq "JohnSmith" • *userName* sw "John" • *externalId eq "0fe44868-31a7-4930-9ah30-757tg2513b64"* • *urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber* eq "00102345"
(Optional) `concur.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *displayName* eq "ProjectTeam1"
(Optional) `concur.group.members.page.size`	The number of group members that SAP Concur returns per request when reading a group. Default value: 1000
(Optional) `concur.group.members.paging.enabled`	This property enables paging of group members. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true*
`concur.group.prefix`	This property distinguishes SAP Concur groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`Concur_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Concur source system and will be provisioned to the target system with the following name pattern: **`Concur_<GroupDisplayName>`**. This way SAP Concur groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Concur groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Concur* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Concur source system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: Concur (Users)

   User v1 API: User v1

   Identity v4 API: Identity v4

   SCIM v4 API: SCIM v4 API

   Default transformation when using User v1 API (connector version 1):

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.EmployeeID",
                "targetVariable": "entityIdSourceSystem",
                "functions": [
                    {
                        "type": "compositeId",
                        "subId": "$.LoginID"
                    }
                ]
            },
            {
                "sourcePath": "$.EmployeeID",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.PrimaryEmail",
                "targetPath": "$.emails[0].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.FirstName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.LastName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
```

```
            {
                "sourcePath": "$.CellPhoneNumber",
                "optional": true,
                "targetPath": "$.phoneNumbers[0].value"
            },
            {
                "sourcePath": "$.LoginID",
                "correlationAttribute": true
            }
        ]
    }
}
```

Default transformation when using Identity v4 API (connector version 2):

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.emails",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.emails"
      },
      {
        "type": "remove",
        "targetPath": "$.emails[*].notifications"
      },
      {
        "sourcePath": "$.name",
        "targetPath": "$.name"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$

['value']",
        "optional": true,
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']"
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['displayName']",
        "optional": true,
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['displayName']"
      },
      {
        "sourcePath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups"
      }
    ]
  }
}
```

Default transformation when using SCIM v4 API (connector version 3):

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
```

```
      "sourcePath": "$.name",
      "targetPath": "$.name"
    },
    {
      "sourcePath": "$.active",
      "targetPath": "$.active"
    },
    {
      "sourcePath": "$.emails",
      "preserveArrayWithSingleElement": true,
      "optional": true,
      "targetPath": "$.emails"
    },
    {
      "type": "remove",
      "targetPath": "$.emails[*].notifications"
    },
    {
      "sourcePath": "$.displayName",
      "optional": true,
      "targetPath": "$.displayName"
    },
    {
      "sourcePath": "$.addresses",
      "preserveArrayWithSingleElement": true,
      "optional": true,
      "targetPath": "$.addresses"
    },
    {
      "sourcePath": "$.timezone",
      "optional": true,
      "targetPath": "$.timezone"
    },
    {
      "sourcePath": "$.phoneNumbers",
      "preserveArrayWithSingleElement": true,
      "optional": true,
      "targetPath": "$.phoneNumbers"
    },
    {
      "targetPath": "$.phoneNumbers[*].issuingCountry",

        "targetPath": "$.groups"
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
```

```
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%concur.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%concur.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "optional": true,
        "preserveArrayWithSingleElement": true
      }
    ]
  }
}
```

5. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.21 SAP CPQ

Follow this procedure to set up SAP CPQ (Configure, Price, and Quote) as a source system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the API of SAP CPQ for reading user and group information.

Context

SAP CPQ is a highly configurable system designated to help sales representatives to configure products, apply pricing and generate quotes. SAP CPQ is part of the SAP Sales Cloud portfolio.

Create an SAP CPQ source system to read users and groups from it.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP CPQ* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP CPQ and configure the authentication method (basic or OAuth certificate-based).

   > ### Note
   >
   > We recommend that you use OAuth certificate-based authentication.

   a. In your newly added SAP CPQ source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

   Skip this step if you use basic authentication. The next steps are relevant for OAuth certificate-based authentication only. For more information, see Configure OAuth Certificate Authentication [page 2456].

   b. Convert your certificate file from `.crt` to `.cer`.

   c. Login to SAP CPQ and navigate to *Security* > *Certificate Management* > *User Certificates* > *New Certificate* and upload the certificate to the technical user of SAP CPQ.

   Make sure the *Enable User Certificates* option is turned on. Additionally, the technical user must be set to *Active*.
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`cpq.user.filter`	(Optional) When specified, only those SAP CPQ users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**
`OAuth2TokenServiceURL`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth 2.0 Token Service URL. For example: `https://<cpq_url>/oauth2/token`
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Specify the password for your technical user.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the URL to the API of your SAP CPQ system. It is the same as your SAP CPQ tenant URL. It must contain the domain name. For example: **https://sample1234.mycpqdomain.com**
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the Username of your SAP CPQ technical user.
`cpq.group.members.page.size`	When the `cpq.group.members.paging.enabled` property is set to true, this setting defines the size of the paged members request. **Note** If you configure `cpq.group.members.page.size` to a number greater than the default value, the complete member retrieval is disabled. Default Value: **100** The number of group members that SAP CPQ returns per request when reading a group.

Property Name	Value
`cpq.group.members.paging.enabled`	This property enables the complete retrieval of group members through additional sequential requests. The maximum number of group members returned per request is 100 as defined in `cpq.group.members.page.size`. For more information, see `cpq.group.members.page.size`. Possible Values: • **true** - Paging is enabled. • **false** - Paging is disabled. Default Value: **true**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP CPQ* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   The behavior of the default transformation logic is to read all user attributes from the source SAP CPQ system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity. You can change the default transformation mapping rules to reflect your current setup of entities in your SAP CPQ system. For more information, see:

   Manage Transformations [page 2439]

   SAP CPQ: SCIM API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
```

```
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.emails[?(@.primary == true)].value",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.addresses",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.addresses"
            },
            {
                "sourcePath": "$.phoneNumbers",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.phoneNumbers"
            },
            {
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.groups",
                "functions": [
                    {
                        "condition": "'%cpq.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%cpq.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
```

```
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%cpq.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%cpq.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.members"
            },
            {  "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            },
            {
                "constant": "authorization",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            }
        ]
    }
}
```

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.22 SAP Data Custodian

Follow this procedure to set up SAP Data Custodian as a source system.

Prerequisites

- You have created an SAP Data Custodian tenant.
- You have created a user within your tenant with the required roles for your scenario.
- You have added your user to SAP Identity Service Management (SAP ISM).

Context

SAP Data Custodian is a robust Software as a Service (SaaS) solution that protects sensitive data stored in public, private, hybrid, and multicloud environments. This solution integrates with partnered public hyperscalers, SAP applications, and SAP managed clouds.

After fulfilling the prerequisites, follow the procedure below to add a source system for SAP Data Custodian to read users and user assignments to groups. This source system consumes SCIM 2.0 API provided by SAP Data Custodian.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Data Custodian* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Data Custodian and configure the authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Data Custodian source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip this step if you use basic authentication. The next steps are performed in SAP Data Custodian and are relevant for certificate-based authentication only.

   b. Login to SAP Data Custodian tenant and create a tenant operations technical user (TOTU), as described in Create a Tenant Operations Technical User in SAP Data Custodian.

   c. Upload the outbound certificate that you downloaded in **substep a.** to the TOTU, as described in Register the Outbound Certificate to Your Tenant Operations Technical User.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP Data Custodian SCIM API excluding the path information. `https://<SCIM_API_URL>` For more information, see Identity Provisioning.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* Enter the OAuth client key, created for your SAP Data Custodian tenant. For more information, see Basic Authentication Prerequisites.
`Password`	Valid if *BasicAuthentication* (Credential) Enter the OAuth client secret, created for your SAP Data Custodian tenant. For more information, see Certificate Authentication Prerequisites.
`OAuth2TokenServiceURL`	Specify the URL of the access token provider service for your SAP Data Custodian instance: `https://<SCIM_API_URL>/kms/scim/v1/Oauth2/Token`
`dc.group.filter`	This property filters groups by display name or externalId. When specified, only those groups matching the filter expression will be read. **Possible values:** • *SAP_Data_Custodian_Auditor* • *SAP_Data_Custodian_Service_Admin* • *SAP_Data_Custodian_Key_Admin* • *SAP_Data_Custodian_Key_User* For example: *displayName eq "SAP_Data_Custodian_Auditor"*

Property Name	Value
`dc.user.filter`	When specified, only those SAP Data Custodian users matching the filter expression will be read. You can filter users by *userName*, *displayName* or *externalId*. **Possible values:** For example: *userName eq "Smith.J"*
`dc.group.prefix`	This property distinguishes SAP Data Custodian groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`DC_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Data Custodian source system and will be provisioned to the target system with the following name pattern: **`DC_<GroupDisplayName>`**. This way SAP Data Custodian groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Data Custodian groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Data Custodian* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   > ### Note
   >
   > During user creation, the expected format for `userName` is email. Hence, the primary email of the user is set for `userName`.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see:

   Manage Transformations [page 2439]

   SAP Data Custodian SCIM 2.0 API

   Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true
            },
            {
              "sourcePath": "$.displayName",
              "optional":true,
              "targetPath": "$.displayName"
            },
            {
              "sourcePath": "$.name.givenName",
              "optional":true,
              "targetPath": "$.name.givenName"
            },
            {
              "sourcePath": "$.name.familyName",
              "optional":true,
              "targetPath": "$.name.familyName"
            },
            {
              "sourcePath": "$.name.formatted",
              "optional":true,
              "targetPath": "$.name.formatted"
            },
            {
              "sourcePath": "$.name.honorificPrefix",
              "optional":true,
              "targetPath": "$.name.honorificPrefix"
            },
            {
              "sourcePath": "$.name.honorificSuffix",
              "optional":true,
              "targetPath": "$.name.honorificSuffix"
            },
            {
              "sourcePath": "$.name.middleName",
              "optional":true,
              "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId",
                "optional": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
```

```
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.groups",
                "targetPath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "functions": [
                    {
                        "condition": "'%dc.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%dc.group.prefix%"
                    }
                ]
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%dc.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%dc.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "optional": true,
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId",
                "optional": true
            },
            {
                "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            },
```

```
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            }
        ]
    }
}
```

6. Now, add a target system to provision users and their group assignments to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Data Custodian

1.6.1.23 SAP Datasphere

Follow this procedure to set up SAP Datasphere as a source system.

Prerequisites

- In SAP Datasphere, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- In SAP Datasphere, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Create OAuth2.0 Clients to Authenticate Against SAP Datasphere

Context

SAP Datasphere is a solution that harmonizes data management, analytics, and intelligent planning, including capabilities of SAP Data Intelligence Cloud and SAP Analytics Cloud. The solution enables SAP customers to consolidate their SAP data and analytics needs into a single SAP solution.

You can use Identity Provisioning to configure SAP Datasphere as a source system where you can read users and provision them to target systems of your choice. The source system consumes SCIM 2.0 API provided by SAP Datasphere.

> **Note**
>
> SAP Datasphere does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Datasphere* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Datasphere system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Datasphere.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Datasphere.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Datasphere instance. This token URL is listed in the *Trusted Identity Providers* section of the *App Integration* page. For more information, see Create OAuth2.0 Clients to Authenticate Against SAP Datasphere

Property Name	Description & Value
(Optional) `ds.user.filter`	When specified, only those SAP Datasphere users matching the filter expression will be read For example: *userName eq "SmithJ"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Datasphere* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Datasphere system. For more information, see: Manage Transformations [page 2439]

   SAP Datasphere SCIM 2.0 API

   Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
              "sourcePath": "$.name.givenName",
              "optional": true,
              "targetPath": "$.name.givenName"
            },
            {
              "sourcePath": "$.name.familyName",
              "optional": true,
              "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
```

```
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:user-custom-parameters']",
                "targetPath": "$
['urn:sap:params:scim:schemas:extension:sac:2.0:user-custom-parameters']"
            },
            {
                "sourcePath": "$.photos",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.photos",
                "optional": true
            },
            {
                "sourcePath": "$.preferredLanguage",
                "targetPath": "$.preferredLanguage",
                "optional": true
            },
            {
                "sourcePath": "$.roles",
                "targetPath": "$.roles",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
                "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
                "optional": true
            }
        ]
    }
}
```

5. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.24 SAP Enable Now

Follow this procedure to set up SAP Enable Now as a source system.

Prerequisites

- You have created a technical user in SAP Enable Now with the necessary permissions for establishing a connection with Identity Provisioning.

Context

The SAP Enable Now solution is SAP's digital adoption platform. It can help you improve the adoption, productivity, and efficiency of your software by providing in-application help and e-learning content to users.

You can use Identity Provisioning to configure SAP Enable Now as a source system where you can read users and provision them to target systems of your choice. The source system consumes SCIM 2.0 API provided by SAP Enable Now.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Enable Now* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Enable Now system. It follows the pattern: • `https://<company-name>.enable-now.cloud.sap` • `https://<company-name>.sap-enable-now.cn` (relevant for China)
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Description & Value
`User`	Enter the username of the SAP Enable Now technical user.
`Password`	(Credential) Enter the password of the SAP Enable Now technical user.
(Optional) `en.user.filter`	When specified, only those SAP Enable Now users matching the filter expression will be read For example: *userName eq "SmithJ"*
(Optional)`en.group.prefix`	This property distinguishes SAP Enable Now groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`EN_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Enable Now source system and will be provisioned to the target system with the following name pattern: **`EN_<GroupDisplayName>`**. This way SAP Enable Now groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Enable Now groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Enable Now* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Enable Now system. For more information, see: Manage Transformations [page 2439]

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
```

```
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.middleName",
                "optional": true,
                "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.active",
                "optional": true,
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.groups",
                "targetPath": "$.groups",
                "optional": true,
                "preserveArrayWithSingleElement": true,
                "functions": [
                    {
                        "condition": "'%en.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%en.group.prefix%"
                    }
                ]
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
```

```
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%en.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%en.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true
            }
        ]
    }
}
```

5. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.25 SAP Enterprise Portal

Follow this procedure to set up SAP Enterprise Portal as a source system.

Prerequisites

- You are using SAP NetWeaver 7.5 Patch Level 22 and higher.
- You have prepared AS Java to use the SCIM application for REST API calls, as described in Initial Setup. This means, you have activated the SCIM application and created and set user authorization.

Context

SAP Enterprise Portal uses and builds on the user management of SAP NetWeaver AS for Java. Using SAP Enterprise Portal, organizations can give their employees, customers, partners, and suppliers a single point of access to the company applications, services, and information needed for conducting daily work. The portal offers business users the capability to easily create and manage portal pages and to generate their own portal content.

You can use Identity Provisioning to configure SAP Enterprise Portal as a source system where you can read users, groups and group assignments and provision them to target systems of your choice. In SAP Enterprise Portal, those entities correspond to users, Portal roles and user assignments to Portal roles, respectively.

> ⓘ Note
>
> When reading groups from SAP Enterprise Portal source system, only the exposed Portal roles are returned. When reading users, only user members of the exposed roles are returned.

In a typical scenario, SAP Enterprise Portal is configured as a source system and SAP Build Work Zone, standard edition [page 1062] is configured as a target system. The SCIM Portal application for AS Java is developed to satisfy the SAP Enterprise Portal and SAP Build Work Zone, standard edition requirements for synchronization of exposed Portal roles and the user assignments to Portal roles.

For more information, see SCIM Portal Application for AS Java

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Enterprise Portal* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API of your SAP Enterprise Portal system. It follows the pattern: `http://<host>:<port>` of SAP NetWeaver where the SAP Enterprise Portal runs on.
`ProxyType`	Enter: *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user name of the technical user you have created following the *Create and Set User Authorization* step in the *Prerequisites* section.
`Password`	(Credential) Enter the password of the technical user you have created following the *Create and Set User Authorization* step in the *Prerequisites* section.
`ep.user.filter`	When specified, only those SAP Enterprise Portal users matching the filter expression will be read. For more information, see Filtering.
`ep.group.filter`	When specified, only those SAP Enterprise Portal groups matching the filter expression will be read. For more information, see Filtering.

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map user and group attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Enterprise Portal* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

SCIM Implementation for AS Java

Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Enterprise Portal system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails",
                "optional": true
            },
            {
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.groups"
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId",
                "optional": true
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
```

```
                "targetPath": "$.schemas"
            }
        ]
    }
}
```

5. Add a target system to provision users and groups to it. For example: SAP Build Work Zone, standard edition [page 1062].

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Enterprise Portal

1.6.1.26 SAP Fieldglass

Follow this procedure to set up a source connector for SAP Fieldglass.

Prerequisites

You have created an API application key and a web service. To do that, follow the steps on page: Create API Application Key or Web Service and Web Services Setup

You will need the values of *Virtual Person Name (Username)* and *License Key* for the configuration of your source system (**step 3** below).

Context

After fulfilling the prerequisites, follow the procedure below to add a source system for SAP Fieldglass to read users and groups from it. This source system consumes SCIM 2.0 API provided by SAP Fieldglass.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Fieldglass* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify your SAP Fieldglass environment URL. For example: *https://abc123.fgvms.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter your *Virtual Person Name (Username)* – see the **Prerequisites** section above.
`Password`	(Credential) Enter your *License Key* – see the **Prerequisites** section above.
`OAuth2TokenServiceURL`	Enter your OAuth token URL in the following format: `https://<Environment_URL>/api/oauth2/v2.0/token` For example: *https://abc123.fgvms.com/api/oauth2/v2.0/token*

Property Name	Value
(Optional) `fg.group.prefix`	This property distinguishes SAP Fieldglass groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **FG_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Fieldglass source system and will be provisioned to the target system with the following name pattern: **FG_<GroupDisplayName>**. This way SAP Fieldglass groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Fieldglass groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **FG_** prefix in their display name will be provisioned to SAP Fieldglass. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Fieldglass.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Fieldglass* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   The behavior of the default transformation logic is to read all user attributes from the source SAP Fieldglass system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Fieldglass

   Default transformation:

   Code Syntax

   ```
   {
   ```

```
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.name.formatted",
        "optional": true,
        "targetPath": "$.name.formatted"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.title",
        "targetPath": "$.title",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.timezone",
        "optional": true,
        "targetPath": "$.timezone"
      },
      {
        "sourcePath": "$.addresses",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.addresses"
      },
      {
        "sourcePath": "$.groups",
```

```
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups",
        "functions": [
          {
            "condition": "'%fg.group.prefix%' !== 'null'",
            "function": "concatString",
            "applyOnElements": true,
            "applyOnAttribute": "display",
            "prefix": "%fg.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$['resourceExtensions']

['displayName']",
        "optional": true
      },
      {
        "sourcePath": "$['resourceExtensions']
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['organization']",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['organization']",
        "optional": true
      }
    ]
  },
// By default, the group mapping is inactive (ignored) but groups are
supported.
// To start provisioning groups, either delete the statement "ignore":
true, or set its value to false.
  "group": {
    "ignore": true,
    "mappings": [
      {
       "sourcePath": "$.id",
       "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
            {
                "condition": "'%fg.group.prefix%' !== 'null'",
                "function": "concatString",
                "prefix": "%fg.group.prefix%"
            }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
```

```
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      }
    ]
  }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.27 SAP Field Service Management

Follow this procedure to set up SAP Field Service Management as a source system.

Prerequisites

You have OAuth credentials for SAP Field Service Management. For more information, see: Generating Client ID & Secret

Context

SAP Field Service Management is a cloud-based solution that is used to resolve customers issues with end-to-end field service management. For example, it helps customers overcome resource limitations, such as having enough skilled technicians in all locations.

You can use the Identity Provisioning user interface (UI) to configure SAP Field Service Management as a source system where you can read users, groups, and group members.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Field Service Management* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Field Service Management system. It follows the pattern: `https://<cluster>.fsm.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Field Service Management system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Field Service Management system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://<cluster>.fsm.cloud.sap/api/oauth2/v2/token`
(Optional) `fsm.user.filter`	When specified, only those SAP Field Service Management users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"** **Note** Using this property makes sense only if you have set the *"ignore": true* statement to **false**.

Property Name	Value
(Optional) `fsm.group.prefix`	This property distinguishes SAP Field Service Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`FSM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Field Service Management source system and will be provisioned to the target system with the following name pattern: **`FSM_<GroupDisplayName>`**. This way SAP Field Service Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Field Service Management groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`FSM_`** prefix in their display name will be provisioned to SAP Field Service Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Field Service Management.
(Optional) `fsm.group.filter`	When specified, only those SAP Field Service Management groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Field Service Management* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   SAP Field Service Management - SCIM API

Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Field Service Management system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.groups",
                "functions": [
                    {
                        "condition": "'%fsm.group.prefix%' !== 'null'",

                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%fsm.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%fsm.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members"
            }
        ]
    }
}
```

5. Add a target system to provision users and groups to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.28 SAP HANA Cloud Database Services

Follow this procedure to set up SAP HANA Cloud Database Services as a source system.

Prerequisites

You have created a technical user for Identity Provisioning in the SAP HANA database with the OPERATOR and ROLE ADMIN system privileges. For more information, see SAP Identity Provisioning Service → *Prerequisites*.

Context

SAP HANA Cloud allows you to consume the SAP HANA database from cloud applications running on SAP Business Technology Platform, as well as from applications running elsewhere using the standard SAP HANA clients. Every instance of SAP HANA Cloud has its own single SAP HANA Database.

You can use Identity Provisioning to configure SAP HANA Cloud Database Services as a source system where you can read users, roles and user role assignments from and provision them to target systems of your choice.

The SAP HANA Cloud Database Services connector supports provisioning of entities to the following two database types:

- SAP HANA Database (HDB)
- SAP HANA Data Lake Relational Engine (HDLRE / IQ Database)

You can define the target database type by setting the `hana.cloud.db.instance.type` property to either `hdb` or `hdlre`.

For more information on the supported database types, see SAP HANA Cloud, SAP HANA Database and SAP HANA Cloud, Data Lake.

> **Note**
>
> In SAP HANA Cloud Database Services, groups correspond to roles.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP HANA Cloud Database Services* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Authentication`	Enter: *BasicAuthentication*
`hana.cloud.db.instance.type`	Refers to the database type configured or used within SAP HANA Cloud. The value can be set to: • **hdb** - SAP HANA Database • **hdlre** - SAP HANA Data Lake Relational Engine Default value: **hdb**
`hana.cloud.db.instance.id`	Refers to a unique identifier associated with a specific database instance within the SAP HANA Cloud.
`hana.cloud.db.user.filter`	(Optional) When specified, only those SAP HANA Cloud Database Services users matching the filter expression will be read. Example: **name.familyName eq "Smith"**
`hana.cloud.db.group.filter`	(Optional) When specified, only those SAP HANA Cloud Database Services roles matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://demo-hc-3-test.authentication.sap.hana.ondemand.com/oauth/token` For more information on how to obtain the value, refer to the procedure in the User Provisioning with Identity Provisioning Service.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the SAP HANA Cloud Database Services API URL. For example: `https://api.gateway.orchestration.<cluster>-<datacenter>.hanacloud.ondemand.com`
`User`	Enter the OAuth Client Id, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP HANA Cloud Database Services* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Manage Transformations [page 2439]

   > ### Note
   >
   > Given that the SAP HANA Database username attribute is immutable and the email is not supported, refer to Handling Specific Attributes for your provisioning scenarios, particularly with Identity Authentication.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },

        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%hana.cloud.db.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%hana.cloud.db.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {
```

```
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "optional": true,
        "preserveArrayWithSingleElement": true
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

User Provisioning

1.6.1.29 SAP Integrated Business Planning

Follow this procedure to set up SAP Integrated Business Planning (in short, SAP IBP) as a source system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Integrated Business Planning, you need to set up the communication (user, system and arrangement) on SAP Integrated Business Planning. You can do it now (as a prerequisite) or in the process of configuring SAP Integrated Business Planning as a source system, as described in step 3.

Context

SAP Integrated Business Planning is a cloud-based solution that combines sales and operations planning (S&OP), forecasting and demand, response and supply, demand-driven replenishment, and inventory planning.

You can use Identity Provisioning to configure SAP IBP as a source system where you can read entities from and provision them to a target system.

SAP Integrated Business Planning provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. By default, the Identity Provisioning service uses API version *1*. The value of the `ibp.api.version` property controls which API you use.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. It supports reading **business users** (employees), **user assignments to business roles**, and **business roles** (considered as *groups*).
  For more information on how to update to version *2*, see Update SAP Integrated Business Planning [page 2432].
- When the value is set to *2*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users**, including their **assignments** to groups of type **userGroup** and **authorization** (roles). For more information, see Groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Integrated Business Planning* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Integrated Business Planning and configure your authentication method (basic or certificate-based).

   > ⓘ Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Integrated Business Planning source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Integrated Business Planning backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

c. Create a communication system and assign the created user to the communication system.

   For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

   - When `ibp.api.version=1` is set in Identity Provisioning for the SAP IBP source system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

     > **Note**
     >
     > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
     >
     > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

   - When `ibp.api.version=2` is set in Identity Provisioning for the SAP IBP source system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

     > **Note**
     >
     > The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value SAP Integrated Business Planning
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP IBP system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value SAP Integrated Business Planning
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`ibp.api.version`	The API version which is consumed by the SAP Integrated Business Planning system. By default, Identity Provisioning uses version *1*.
`ibp.skip.read.archived`	In the event of archived (disabled) entities in a source SAP IBP system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it. **Relevant for connector version 1**
`ips.date.variable.format`	*yyyy-MM-dd*
(Optional) `ibp.roles.filter`	Enter OData filtering for reading roles in the SAP IBP system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option** **Relevant for connector version 1**
(Optional) `ibp.group.filter`	When specified, only those SAP Integrated Business Planning groups matching the filter expression will be read. Supported operators: eq (equal), co (contains), and sw (starts with). **Possible values:**: • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For more information, see List of Properties [page 80]. **Relevant for connector version 2**

Property Name	Description & Value SAP Integrated Business Planning
(Optional) `ibp.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP IBP system. The value must be an integer number. **Relevant for connector version 1**
(Optional) `ibp.roles.prefix`	This property distinguishes SAP Integrated Business Planning roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IBP_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be pre-pended to the name of the roles that are read from the SAP Integrated Business Planning source system and will be provisioned to the target system with the following name pattern: **`IBP_<role_name>`** . This way SAP Integrated Business Planning roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Integrated Business Planning roles will be read and provisioned to the target system with their actual role names. **Relevant for connector version 1**

Property Name	Description & Value SAP Integrated Business Planning
(Optional) `ibp.group.prefix`	This property distinguishes SAP Integrated Business Planning groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IBP_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Integrated Business Planning source system and will be provisioned to the target system with the following name pattern: **`IBP_<GroupDisplayName>`**. This way SAP Integrated Business Planning groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Integrated Business Planning groups will be read and provisioned to the target system with their actual display names. For more information, see List of Properties [page 80]. **Relevant for connector version 2**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://my1234567-api.scmibp.ondemand.com*

`User`=*MyIBPuser*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`ibp.skip.read.archived`=*true*

`ibp.roles.filter`=*startswith(ID, 'EMPLOYEE_LEVEL_3') eq true*

`ibp.roles.page.size`=*30*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default

transformation for the *SAP IBP* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules depending on your setup of entities in your SAP IBP. For more information, see:

Manage Transformations [page 2439]

SAP Integrated Business Planning API: Business User

        "optional": true
      },
      {
        "sourcePath": "$.to_BusinessUserAssignment.results",
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].__metadata"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].UserName"
      },
      {
        "type": "rename",
        "constant": "value",
        "targetPath": "$.members[*].PersonID"
      },
      {
        "constant": "User",
        "targetPath": "$.members[*].type"
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

Default transformation for connector version 2:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },

        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      }
    ]
  }
}
```

> ### Note
>
> If you are using SAP Integrated Business Planning version 2511, note that the `timeZone` value is not provided in the `IANA` format required by SCIM. To fix this, you need to manually add the `convertTimezoneCode` function within the `timeZone` mapping, as shown below:
>
> ```
> {
>    "sourcePath":"$.timeZone",
>    "optional":true,
>    "targetPath":"$.timezone",
>    "functions":[
>       {
>          "type":"convertTimezoneCode",
>          "outputFormat":"iana"
>       }
>    ],
>    "defaultValue":"Europe/Berlin"
> },
> ```

Group Uniqueness and Provisioning

In the most common scenario, SAP Integrated Business Planning connector version 2 is used as the source system for groups and Identity Authentication connector version 2 or Local Identity Directory is the target system.

In SAP Integrated Business Planning version 2, the uniqueness of a group is defined by the combination of `externalId` and `type` attributes. The system supports two group types: `userGroup` and `authorization` (role). As a result, two different groups can share the same `externalId` while belonging to different types, potentially causing conflicts when provisioned to the target system.

To avoid conflicts, ensure the following:

- Your SAP Integrated Business Planning system is updated to version 2, as described in Update SAP Integrated Business Planning [page 2432].
- Your target system (Identity Authentication version 2 or Local Identity Directory) has the respective group uniqueness property: `ias.group.unique.attribute` or `idds.group.unique.attribute`, set with the following combination of values: `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`, `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']`, `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`. For more information, see List of Properties [page 80].
  Because the `externalId` attribute in SAP Integrated Business Planning version 2 connector is mapped to the `name` attribute in the target, when a group of type `userGroup` is provisioned from the source to the target, the suffix `:userGroup` is automatically appended to its `name`. This ensures that even if two groups share the same `externalId`, their names remain unique in the target system.

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Integrated Business Planning

1.6.1.30 SAP Intelligent Agriculture

Follow this procedure to set up SAP Intelligent Agriculture as a source system.

Prerequisites

- You have onboarded your SAP Intelligent Agriculture tenant as described in the Onboarding with the SAP BTP Cockpit section of the *Administration Guide for SAP Intelligent Agriculture*.

- You have OAuth credentials for SAP Intelligent Agriculture. For more information, see: Getting the Credentials from the SAP Intelligent Agriculture Instance.

Context

SAP Intelligent Agriculture enables agribusinesses to sustainably increase farming efficiency by digitizing their farming processes and services from plan-to-harvest, taking advantage of data science and machine learning capabilities.

After fulfilling the prerequisites, follow the procedure below to create a source SAP Intelligent Agriculture system to read users and groups.

These source systems consume SCIM 2.0 API provided by SAP Intelligent Agriculture.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Intelligent Agriculture* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Intelligent Agriculture system, in format: **`https://*.prod-<region>.ia.agribusiness.cloud.sap`** , where *: is the name of your subaccount. For example: **`https://custom-domain.prod-eu10.ia.agribusiness.cloud.sap`**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Intelligent Agriculture instance, in format: **`https://<TENANT>.authentication.<REGION>.hana.ondemand.com/oauth/token`**
(Optional) `ia.group.filter`	When specified, only those SAP Intelligent Agriculture groups matching the filter expression will be read. **Possible values:** • *intagri_Data_Scientist* • *intagri_Farm_Manager* • *intagri_Operator* • *intagri_Operations_Planner* • *intagri_Master_Data_Manager* • *intagri_Administrator* For example: *displayName eq "intagri_Master_Data_Manager"* For more information, see List of Properties [page 80]
(Optional) `ia.user.filter`	When specified, only those SAP Intelligent Agriculture users matching the filter expression will be read. For example: *userName eq "Smith.J"* For more information, see List of Properties [page 80]
(Optional)`ia.group.prefix`	This property distinguishes SAP Intelligent Agriculture groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IA_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Intelligent Agriculture source system and will be provisioned to the target system with the following name pattern: **`IA_<GroupDisplayName>`**. This way SAP Intelligent Agriculture groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Intelligent Agriculture groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Intelligent Agriculture* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Intelligent Agriculture system. For more information, see:

   Manage Transformations [page 2439]

   SAP Intelligent Agriculture SCIM API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "($.userName != 'ANONYMOUS' && $.userUuid !=
'ANONYMOUS' && $.externalId != 'ANONYMOUS' )",
//When a user is deleted from the SAP Intelligent Agriculture system, its
unique attributes are set to value 'ANONYMOUS'. Such users are skipped by
the read provisioning jobs.
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",

            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.userUuid",
                "targetPath": "$.userUuid"
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.middleName",
                "optional": true,
                "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
```

```
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.emails[0].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.groups",
                "targetPath": "$.groups",
                "optional": true,
                "preserveArrayWithSingleElement": true,
                "functions": [
                    {
                        "function": "concatString",
                        "condition": "'%ia.group.prefix%' !== 'null'",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%ia.group.prefix%"
                    }
                ]
            }
        ]
    },
    "group": {
    "mappings": [
      {
        "sourcePath": "$.schemas",
        "targetPath": "$.schemas",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "function": "concatString",
            "condition": "'%ia.group.prefix%' !== 'null'",
            "prefix": "%ia.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
```

```
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "optional": true,
        "preserveArrayWithSingleElement": true
      }
    ]
  }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.31 SAP Jam Collaboration

Follow this procedure to set up SAP Jam Collaboration as a source system.

Prerequisites

You get OAuth credentials for SAP Jam Collaboration. If your SAP Jam tenant is of "SCIM provisioning" type, an OAuth client is automatically created for it, with the name **SCIM API Client**. To find this client:

1. Go to the SAP Jam Collaboration admin panel.
2. Choose *Integrations* > *OAuth Clients*.

3. For *SCIM API Client*, choose *View*.
4. Save the *Key* and *Secret* values – you'll need them later while configuring your SAP Jam Collaboration provisioning system.

To learn more, see: SAP Jam: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a source SAP Jam Collaboration system to read users and groups.

These source systems consume SCIM 2.0 API provided by SAP Jam Collaboration.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Jam Collaboration* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Jam system, in format: **`https://<SAP_Jam_datacenter>.sapjam.com`** For example: *https://jam4.sapjam.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth client key, created for your SAP Jam tenant (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth client secret, created for your SAP Jam tenant (see **Prerequisites**).
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Jam instance, in format: **`https://<SAP_Jam_datacenter>/api/v1/auth/token`** For example: *https://jam4.sapjam.com/api/v1/auth/token*

Property Name	Description & Value
(Optional) `jam.group.prefix`	This property distinguishes SAP Jam Collaboration groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SJC_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Jam Collaboration source system and will be provisioned to the target system with the following name pattern: **`SJC_<GroupDisplayName>`**. This way SAP Jam Collaboration groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Jam Collaboration groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Jam Collaboration* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Jam Collaboration system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Jam Collaboration

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "correlationAttribute": true
            },
```

```
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "type": "remove",
                "targetPath": "$.id"
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            }
        ]
    },
    "group": {
        "ignore": true,
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%jam.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%jam.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "type": "remove",
                "targetPath": "$.id"
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            },
            {
                "condition" : "'%ips.application.id%'!== 'null'",
                "constant" : "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true,
```

```
"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.32 SAP Market Communication for Utilities

Follow this procedure to set up SAP Market Communication for Utilities as a source system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Market Communication for Utilities, you need to set up the communication user in SAP BTP ABAP environment. You can do it now (as a prerequisite) or in the process of configuring SAP Market Communication for Utilities as a source system, as described in step 3.

Context

The SAP Market Communication for Utilities application is based on SAP BTP ABAP environment. You can use Identity Provisioning to configure SAP Market Communication for Utilities as a source system to read entities from and provision them to a target system.

This scenario supports reading **business users** (Employee), **user assignments**, and **business roles** (which are considered as *groups*).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Market Communication for Utilities* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Market Communication for Utilities and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Market Communication for Utilities source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP BTP ABAP environment backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

      For more information, see Maintain a Communication Arrangement for Inbound Communication

      > ### Note
      >
      > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
      >
      > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP Market Communication for Utilities system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`maco.skip.read.archived`	In the event of archived (disabled) entities in a source SAP Market Communication for Utilities system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd*
(Optional) `maco.roles.filter`	Enter OData filtering for reading roles in the SAP Market Communication for Utilities system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**

Property Name	Description & Value
(Optional) `maco.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP Market Communication for Utilities system. The value must be an integer number.
(Optional) `maco.roles.prefix`	This property distinguishes SAP Market Communication for Utilities roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SMC_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP Market Communication for Utilities source system and will be provisioned to the target system with the following name pattern: **`SMC_<role_name>`** . This way SAP Market Communication for Utilities roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Market Communication for Utilities roles will be read and provisioned to the target system with their actual role names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://12345-aaaaa-3333.abap.hana.ondemand.com*

`User`=*MyMaCoUser*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`maco.skip.read.archived`=*true*

`maco.roles.filter`=*startswith(ID, 'EMPLOYEE_LEVEL_3') eq true*

`maco.roles.page.size`=*30*

5. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Market Communication for Utilities* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules depending on your setup of entities in your SAP Market Communication for Utilities. For more information, see:

Manage Transformations [page 2439]

SAP S/4HANA Cloud Public Edition API: Business User

Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "($.validityPeriod.startDate <= '${currentDate}') &&
($.validityPeriod.endDate > '${currentDate}')",
    "mappings": [
      {
        "sourcePath": "$.personID",

      },
      {
        "sourcePath": "$.ID",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.to_BusinessUserAssignment.results",
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].__metadata"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].UserName"
      },
      {
        "type": "rename",
        "constant": "value",
        "targetPath": "$.members[*].PersonID"
      },
      {
```

```
        "constant": "User",
        "targetPath": "$.members[*].type"
      },
      {
        "condition": "'%ips.application.id%'!== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "constant": "authorization",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP S/4HANA Cloud Public Edition Documentation

1.6.1.33 SAP Marketing Cloud

Follow this procedure to set up SAP Marketing Cloud as a source system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Marketing Cloud, you need to set up the communication (user, system and arrangement) on SAP Marketing Cloud. You have the option to do it either now, as a prerequisite, or while configuring SAP Marketing Cloud as a source system, as described in step 3.

Context

You can use SAP Marketing Cloud to read entities from it and provision them to a target system. This scenario supports reading **users**, **user assignments**, and **Business roles** (which are considered as *groups*).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Marketing Cloud* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Marketing Cloud and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Marketing Cloud source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Marketing Cloud backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

   For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

   > **Note**
   >
   > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
   >
   > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP Marketing Cloud system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`marketing.cloud.skip.read.archived`	In the event of archived (disabled) entities in a source SAP Marketing Cloud system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd*
(Optional) `marketing.cloud.roles.filter`	Enter OData filtering for reading roles in the SAP Marketing Cloud system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**
(Optional) `marketing.cloud.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP Marketing Cloud system. The value must be an integer number.
(Optional) `marketing.cloud.roles.prefix`	This property distinguishes SAP Marketing Cloud roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`SMKC_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP Marketing Cloud source system and will be provisioned to the target system with the following name pattern: **`SMKC_<role_name>`** . This way SAP Marketing Cloud roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP Marketing Cloud roles will be read and provisioned to the target system with their actual role names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://my1234567-api.s4hana.ondemand.com
User=MyMarketingCloudUser
Password=************
ips.date.variable.format=yyyy-MM-dd
marketing.skip.read.archived=true
marketing.cloud.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
marketing.cloud.roles.page.size=30
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Marketing Cloud* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in your SAP Marketing Cloud. For more information, see:

   Manage Transformations [page 2439]

   SAP Marketing Cloud API: Business User

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "($.validityPeriod.startDate <= '${currentDate}') &&
($.validityPeriod.endDate > '${currentDate}')",
    "mappings": [
      {
        "sourcePath": "$.personID",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.personalInformation.firstName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.lastName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.middleName",
        "targetPath": "$.name.middleName",
```

```
        "optional": true
      },
      {
        "sourcePath": "$.personalInformation.personFullName",
        "targetPath": "$.name.formatted",
        "optional": true
      },
      {

            "function": "concatString",
            "applyOnElements": true,
            "prefix": "",
            "applyOnAttribute": "roleName",
            "assignToAttribute": "value"
          }
        ]
      },
      {
        "type": "remove",
        "targetPath": "$.groups[*].roleName"
      },
      {
        "sourcePath": "$.user.timeZoneCode",
        "optional": true,
        "targetPath": "$.timezone",
        "functions": [
          {
            "type": "convertTimezoneCode",
            "outputFormat": "iana"
          }
        ],
        "defaultValue": "Europe/Berlin"
      },
      {
        "type": "valueMapping",
        "sourcePaths": [
          "$.businessPartnerRoleCode"
        ],
        "targetPath": "$.userType",
        "defaultValue": "Employee",
        "valueMappings": [
          {
            "key": [
              "BUP003"
            ],
            "mappedValue": "Employee"
          },
          {
            "key": [
              "BBP005"
            ],
            "mappedValue": "Contingent Worker"
          }
        ]
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "sourcePath": "$.ID",
        "targetVariable": "entityIdSourceSystem"
      },
      {
```

```
        "sourcePath": "$.ID",
        "functions": [
          {
            "condition": "'%marketing.cloud.roles.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%marketing.cloud.roles.prefix%"
          }
        ],
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.ID",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.to_BusinessUserAssignment.results",
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].__metadata"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].UserName"
      },
      {
        "type": "rename",
        "constant": "value",
        "targetPath": "$.members[*].PersonID"
      },
      {
        "constant": "User",
        "targetPath": "$.members[*].type"
      },
      {  "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "constant": "authorization",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP S/4HANA Cloud Documentation

1.6.1.34 SAP Master Data Integration

Follow this procedure to set up SAP Master Data Integration (in short, MDI) as a source system.

Prerequisites

- You have created a tenant in a subaccount on SAP BTP, Cloud Foundry environment. You can create your own tenant (free of charge), or integrate with an existing one.
- You have created a service instance for MDI in the subaccount in order to connect a new system to your tenant and read user account information from it. To learn how, see: Creating Service Instances
- You have created a service key in this instance, which contains the necessary credentials to connect to the MDI service. Creating multiple service keys in the same service instance is not supported. To learn how, see: Creating service Instances

> → Tip
>
> The *serviceKey* payload provides you with the following properties that you will later need for your system configuration:
>
> - **uri** =`URL`
> - **uaa.url** = `OAuth2TokenServiceURL`
> - **uaa.clientid** = `User`
> - **clientsecret** = `Password`

Context

As part of SAP's data model and integration unification strategy, SAP BTP Integration Suite has *Master Data Integration* to enable a harmonized integration and distribution of different master data objects and data between SAP solutions. This includes master data for business partners, cost centers, and workforce data. Workforce data is provided for integration scenarios that need data from SAP SuccessFactors Employee Central or other HR systems.

To learn more, see: Integrating SAP SuccessFactors Employee Central with SAP Master Data Integration

You can use Identity Provisioning to configure SAP Master Data Integration as a source system for provisioning of users and HR events to a target system of your choice. The HR events reflect the various stages of an employee's lifecycle from hire to retire. For example: hire, termination, job change, position change. For more information, see Events in Employee Central.

HR events are read with delta load marker so that the target system is aware of the previous and current instance of the event. The delta load marker is deleted during system reset.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Master Data Integration* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to the relevant integration application running in the relevant region of SAP Business Technology Platform. See the **Prerequisites** section → *serviceKey* tip.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user that has access to the API of your MDI service. See the **Prerequisites** section → *serviceKey* tip.
`Password`	(Credential) Enter the password for this technical user. See the **Prerequisites** section → *serviceKey* tip.

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. See the **Prerequisites** section → *serviceKey* tip.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Master Data Integration* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your MDI source system. For more information, see:

   Manage Transformations [page 2439]

   Field Mapping Between Employee Central and SAP Master Data Integration

   Default transformation:

   Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:sfsf:2.0:User']['personGUID']",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['employeeNumber']",
        "optional": true
      },
      {
        "sourcePath":
"$.profileDetail[0].content.scriptedProfileDetails[0].firstName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath":
"$.profileDetail[0].content.scriptedProfileDetails[0].lastName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath":
"$.profileDetail[0].content.scriptedProfileDetails[0].middleName",
        "targetPath": "$.name.middleName",
        "optional": true
```

```
      },
      {
        "sourcePath": "$.userAccount.userName",
        "targetPath": "$.userName",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "constant": true,
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.emails[?(@.isDefault == true)].address",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.emails",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.emails"
      },
      {
        "targetPath": "$.emails[*].usage",
        "type": "remove"
      },
      {
        "targetPath": "$.emails[*].address",
        "type": "rename",
        "constant": "value"
      },
      {
        "targetPath": "$.emails[*].isDefault",
        "type": "rename",
        "constant": "primary"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",
          "urn:sap:cloud:scim:schemas:extension:sfsf:2.0:User",
          "urn:ietf:params:scim:schemas:extension:enterprise:2.0:User"
        ],
        "targetPath": "$.schemas"
      }
    ]
  },
  "event": {
    "ignore": true,
    "condition": "($.instance.id EMPTY false) || ($.instanceId EMPTY
false)",
    "mappings": [
      {
        "sourcePath": "$.instance.id",
        "optional": true,
        "targetPath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.instanceId",
        "optional": true,
        "targetPath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$",
        "targetPath": "$"
      }
    ]
```

```
    }
}
```

5. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Community: The New Master Data Integration Service for SAP SuccessFactors

1.6.1.35 SAP Revenue Growth Management

Follow this procedure to set up SAP Revenue Growth Management as a source system.

Prerequisites

- You have created an SAP Revenue Growth Management consumer application in your SAP Cloud Identity Services tenant and defined a dependency to its API, as described in Configure Integration Between Applications. *UserImport* must be selected for the dependency *API*.
- You have generated API credentials for the consumer application, as described in Generate Credentials to Access the APIs of an Application.

Context

SAP Revenue Growth Management is an SAP BTP SaaS application that provides customers in the Consumer Products industry an easy way to efficiently create, monitor, and maintain account plans.

You can use Identity Provisioning to configure SAP Revenue Growth Management as a source system to read users and groups. These source systems consume SCIM 2.0 API provided by SAP Revenue Growth Management. For more information, see SAP Revenue Growth Management SCIM API.

> **Note**
>
> Support for groups is intended for future use.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Revenue Growth Management* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the base URL of your SAP Revenue Growth Management system's SCIM API, excluding any path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`Password`	(Credential) Enter the client secret generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`rgm.userImport.api.dependency.name`	Enter the value of the dependency name used in the configuration of the SAP Revenue Growth Management consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. For more information, see Integrating Applications.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.

Property Name	Description & Value
(Optional) `rgm.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails[0].value`**, and **`externalId`**, according to the API syntax of SAP Revenue Growth Management. For example: • *userName eq "johnbrown" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName sw "J" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* **Note** These combinations are valid for both 'or' and 'and' operators.
(Optional) `rgm.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group: name eq "ProjectTeam1" or "Students2018"*

Property Name	Description & Value
(Optional) `rgm.group.prefix`	This property distinguishes SAP Revenue Growth Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`RGM_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Revenue Growth Management source system and will be provisioned to the target system with the following name pattern: **`RGM_<GroupDisplayName>`**. This way SAP Revenue Growth Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Revenue Growth Management groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Revenue Growth Management* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Revenue Growth Management system. For more information, see:

   Manage Transformations [page 2439]

   SAP Revenue Growth Management SCIM API

   Default transformation:

   Code Syntax

```
{
  "user":{
    "mappings":[
      {
        "sourcePath":"$.id",
        "targetVariable":"entityIdSourceSystem"
      },
      {

        "functions": [
            {
                "condition": "'%rgm.group.prefix%' !== 'null'",
                "function": "concatString",
                "prefix": "%rgm.group.prefix%"
            }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
            {
                "condition": "'%rgm.group.prefix%' !== 'null'",
                "function": "concatString",
                "prefix": "%rgm.group.prefix%"
            }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "optional": true,
        "preserveArrayWithSingleElement": true
```

```
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      }
    ]
  }
}
```

5. Now, add a target system to provision users and groups into it. Choose from:Target Systems [page 936].

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Revenue Growth Management

1.6.1.36 SAP Sales Cloud and SAP Service Cloud

Follow this procedure to set up SAP Sales Cloud and SAP Service Cloud, formerly known as *SAP Cloud for Customer* (in short, C4C), as a source system.

Prerequisites

To integrate SAP Sales Cloud and SAP Service Cloud with Identity Provisioning, you need to use SAP Cloud Integration (SAP CI). This service provides a package with integration flows (iFlows) for enabling the creation of users and assignment of users to groups via SCIM API in SAP Sales Cloud and SAP Service Cloud.

- To configure SAP Cloud Integration and SAP Sales Cloud and SAP Service Cloud, see: Identity Provisioning in SAP Cloud for Customer using System for Cross-Domain Identity Management (SCIM)
- To set up and use the *SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management* package, see: SAP Business Accelerator Hub: SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management

Context

SAP Sales Cloud and SAP Service Cloud is a cloud-based solution that helps customers manage day-to-day sales and service interactions by sending and receiving signals between front- and back-office solutions and providing a single view of the customer.

You can use Identity Provisioning to configure SAP Sales Cloud and SAP Service Cloud as a source system where you can read *business users*, *employee users*, and *groups* from and provision them to a target system.

The cloud-based solution provides different APIs for integration with Identity Provisioning, leading to different connector versions for each API. Currently, the following connector versions are available: Version 1 (SOAP-based API), which is deprecated, Version 2 (SOAP-based API), Version 3 (SCIM 2.0 based API) and Version 4 (SCIM 2.0 based API), which is applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only.

Each connector version supports specific attribute mappings in transformations and requires particular properties. The latest version is set as the default.

Version 4 (Applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only)

When using connector version 4 (SCIM 2.0 based API), only users of type `Employee` are provisioned. This version introduces an enhanced SCIM API that no longer requires SAP Cloud Integration. It supports the delta read method for retrieving changed data, the **`sw`** filtering operator for user searches, and reading of application-specific groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.

2. Add *SAP Sales Cloud and SAP Service Cloud* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter SAP Cloud Integration runtime URL. See: How to Get SAP Cloud Integration Runtime URL
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`OAuth2TokenServiceURL`	Enter the URL to the access token provider service. For example: `https://<c4c_instance>/auth/token` SAP Sales Cloud and SAP Service Cloud support OAuth token-based authentication, enabling you to obtain an access token using either basic authentication (by setting `User` and `Password`) or certificate authentication. **Relevant for connector version 4**
`User`	Enter SAP Cloud Integration user ID to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**
`Password`	(Credential) Enter SAP Cloud Integration password to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**

Property Name	Description & Value
`c4c.api.version`	The version of the SAP Sales Cloud and SAP Service Cloud API you use. By default, the Identity Provisioning service uses version **4** - the SCIM 2.0 based API.
(Optional) `c4c.user.filter`	When specified, only those users matching the filter expression will be read. Supported user filters in connector version 4: • userName eq "Smith" • userName sw "Sm" • userName eq "Smith" and emails.value eq "smith@example.com" Supported user filter in connector version 3: • addresses.country eq "USA"
(Optional) `c4c.group.filter`	When specified, only those groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1"**
(Optional)`c4c.group.prefix`	This property distinguishes SAP Sales Cloud and SAP Service Cloud groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`C4C_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Sales Cloud and SAP Service Cloud source system and will be provisioned to the target system with the following name pattern: **`C4C_<GroupDisplayName>`**. This way SAP Sales Cloud and SAP Service Cloud groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Sales Cloud and SAP Service Cloud groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

The Identity Provisioning offers a default transformation for the *SAP Sales Cloud and SAP Service Clouds* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in C4C. For more information, see Manage Transformations [page 2439].

Default transformation for connector version 3

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },

      }
    ]
  }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.37 SAP Signavio Process Transformation Suite

Follow this procedure to set up SAP Signavio Process Transformation Suite as a source system.

Prerequisites

> **Note**
>
> The initial setup of SAP Signavio Process Transformation Suite is completed during the onboarding process. This setup includes establishing a connection between Identity Provisioning and SAP Signavio Process Transformation Suite using certificate-based authentication. Any changes needed after the initial setup should be processed through a support incident.

Context

SAP Signavio Process Transformation Suite helps you understand, improve, and transform your business processes – fast and at scale – with a cloud-based process management platform.

You can use Identity Provisioning to configure SAP Signavio Process Transformation Suite as a source system where you can read users and groups from and provision them to a target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP Signavio Process Transformation Suite* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	The URL to the SCIM API of your SAP Signavio Process Transformation Suite system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`sig.tenant.id`	Enter the identifier of your SAP Signavio Process Transformation Suite tenant.
`sig.group.members.paging.enabled`	This property enables paging of group members. Default value: *true*
`sig.user.groups.paging.enabled`	This property enables paging of user's groups. Default value: *true*
`sig.group.members.page.size`	The number of group members that SAP Signavio Process Transformation Suite returns per request when reading a group. Default value = 1000
`sig.user.groups.page.size`	The number of user groups that SAP Signavio Process Transformation Suite returns per request when reading a user. Default value = 1000
(Optional) `sig.user.filter`	When specified, only those SAP Signavio Process Transformation Suite users matching the filter expression will be read. For example: • Value = *userName eq "JohnSmith"* • Value = *userName sw "J"*

Property Name	Value
(Optional) `sig.group.filter`	When specified, only those SAP Signavio Process Transformation Suite groups matching the filter expression will be read. For example: • Value = *displayName eq "ProjectTeam1"* • Value = *displayName sw "P"*
`sig.group.prefix`	This property distinguishes SAP Signavio Process Transformation Suite groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: SIG_ You can use the example value or provide your own. When set in the source system, the prefix will be prepended to the name of the groups that are read from the SAP Signavio Process Transformation Suite source system and will be provisioned to the target system with the following name pattern: SIG_. This way SAP Signavio Process Transformation Suite groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Signavio Process Transformation Suite groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Signavio Process Transformation Suite* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP Signavio Process Transformation Suite system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   Default transformation:

Code Syntax

      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members"
      }
    ]
  }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Signavio Process Transformation Suite

1.6.1.38 SAP S/4HANA Cloud Public Edition

Follow this procedure to set up SAP S/4HANA Cloud Public Edition as a source system.

Prerequisites

To establish the connection between Identity Provisioning and SAP S/4HANA Cloud Public Edition, you need to set up the communication (user, system and arrangement) on SAP S/4HANA Cloud Public Edition. You have the option to do it either now, as a prerequisite, or while configuring SAP S/4HANA Cloud Public Edition as a source system, as described in step 3.

Context

SAP S/4HANA Cloud Public Edition is a complete enterprise resource planning (ERP) system with built-in intelligent technologies and advanced analytics.

You can use Identity Provisioning to configure SAP S/4HANA Cloud Public Edition as a source system where you can read entities from and provision them to target systems of your choice.

SAP S/4HANA Cloud Public Edition provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `s4hana.cloud.api.version` property controls which API you use. By default, the Identity Provisioning service uses version *1*.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. It supports reading **business users** (Employee, Contingent Worker), **user assignments**, and **business roles** (which are considered as *groups*).
- When the value is set to *3*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users** with their **assignments** to groups of type **userGroup** and **authorization**. For more information, see Groups.

For more information on how to update to version *3*, see Update SAP S/4HANA Cloud Public Edition [page 2435].

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP S/4HANA Cloud Public Edition* as a source system. For more information, see Add New Systems [page 2415].

3. Set up the communication between Identity Provisioning and SAP S/4HANA Cloud Public Edition and configure your authentication method (basic or certificate-based).

> ### Note
>
> We recommend that you use certificate-based authentication.

   a. In your newly added SAP S/4HANA source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP S/4HANA backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      - When `s4hana.cloud.api.version=1` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition source system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

        > ### Note
        >
        > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
        >
        > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

      - When `s4hana.cloud.api.version=3` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition source system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

        > ### Note
        >
        > The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP S/4HANA Cloud Public Edition API URL. You can find the correct URL in the *API-URL* field of the communication arrangement set up for the communication scenario used. For example: `https://my123456-api.s4hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`s4hana.cloud.skip.read.archived`	In the event of archived (disabled) entities in a source SAP S/4HANA Cloud Public Edition system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it. **Relevant for connector version 1**
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value
`s4hana.cloud.api.version`	The version of the system API you use. By default, Identity Provisioning uses version *1*. Version *1* means your SAP S/4HANA Cloud Public Edition system consumes SAP S/4HANA Cloud Public Edition API: Business User. Version *3* means your SAP S/4HANA Cloud Public Edition system consumes System for Cross-domain Identity Management (SCIM) API.
(Optional) `s4hana.cloud.roles.filter`	Enter OData filtering for reading roles in the S/4HANA system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option** **Relevant for connector version 1**
(Optional) `s4hana.cloud.group.filter`	When specified, only those SAP S/4HANA Cloud Public Edition groups matching the filter expression will be read. Supported operators: eq (equal), co (contains), and sw (starts with). **Possible values:**: • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For more information, see List of Properties [page 80]. **Relevant for connector version 3**

Property Name	Description & Value
(Optional) `s4hana.cloud.user.filter`	When specified, only those SAP S/4HANA Cloud Public Edition users matching the filter expression will be read. You can filter users by **list of attributes** according to the API syntax of SAP S/4HANA Cloud Public Edition. You can set a single attribute or multiple ones as filter criteria. If you enter multiple attributes (using OR operator), the filter will search for any of them. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values:** • `userName` • `externalId` • `emails[0].value` For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName sw "J" or externalId eq "P000252"* • *userName eq "johnbrown" and emails[0].value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails[0].value ne "johnbrown@email.com" or externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators. **Relevant for connector version 3**
(Optional) `s4hana.cloud.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP S/4HANA Cloud Public Edition system. The value must be an integer number. **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `s4hana.cloud.group.prefix`	This property distinguishes SAP S/4HANA Cloud Public Edition groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`S4HANACLOUD_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP S/4HANA Cloud Public Edition source system and will be provisioned to the target system with the following name pattern: **`S4HANACLOUD_<GroupDisplayName>`**. This way SAP S/4HANA Cloud Public Edition groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP S/4HANA Cloud Public Edition groups will be read and provisioned to the target system with their actual display names. For more information, see List of Properties [page 80]. **Relevant for connector version 3**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://my1234567-api.s4hana.ondemand.com
User=MyS4HANAuser
Password=************
s4hana.cloud.api.version=1
ips.date.variable.format=yyyy-MM-dd
s4hana.cloud.skip.read.archived=true
s4hana.cloud.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
s4hana.cloud.roles.page.size=30
```

5. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA Cloud Public Edition* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules depending on your setup of entities in your SAP S/4HANA Cloud Public Edition. For more information, see:

Manage Transformations [page 2439]

SAP S/4HANA Cloud API: Business User

System for Cross-domain Identity Management (SCIM)

Integrate Cross-Domain Identity Management

Default transformation for connector version 1:

            "prefix": "%s4hana.cloud.roles.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.ID",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schemas[0]"
      },
      {
        "constant": "authorization",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {
        "constant": "readWrite",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      },
      {  "condition": "'%ips.application.id%' !== 'null'",
         "constant": "%ips.application.id%",
         "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$.to_BusinessUserAssignment.results",
        "optional": true,
        "preserveArrayWithSingleElement": true,
```

```
        "targetPath": "$.members"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].__metadata"
      },
      {
        "type": "remove",
        "targetPath": "$.members[*].UserName"
      },
      {
        "type": "rename",
        "constant": "value",
        "targetPath": "$.members[*].PersonID"
      },
      {
        "constant": "User",
        "targetPath": "$.members[*].type"
      }
    ]
  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource. To learn how, see Guided Answers: Business Role Description.

Default transformation for connector version 3:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },

            "function": "concatString",
            "prefix": "%s4hana.cloud.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      }
    ]
  }
}
```

Group Uniqueness and Provisioning

In the most common scenario, SAP S/4HANA Cloud Public Edition connector version 3 is used as the source system for groups and Identity Authentication version 2 or Local Identity Directory is the target system.

In SAP S/4HANA Cloud Public Edition version 3, the uniqueness of a group is defined by the combination of `externalId` and `type` attributes. The system supports two group types: `userGroup` and `authorization`. As a result, two different groups can share the same `externalId` while belonging to different types, potentially causing conflicts when provisioned to the target system.

To avoid conflicts, ensure the following:

- Your SAP S/4HANA Cloud Public Edition system is updated to version 3, as described in Update SAP S/4HANA Cloud Public Edition [page 2435].
- Your target system (Identity Authentication version 2 or Local Identity Directory) has the respective group uniqueness property: `ias.group.unique.attribute` or `idds.group.unique.attribute`, set with the following combination of values: `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`, `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']`, `['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`. For more information, see List of Properties [page 80].
  Because the `externalId` attribute in SAP S/4HANA Cloud Public Edition connector version 3 is mapped to the `name` attribute in the target, when a group of type `userGroup` is provisioned from the source to the target, the suffix `:userGroup` is automatically appended to its `name`. This ensures that even if two groups share the same `externalId`, their names remain unique in the target system.

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP S/4HANA Cloud Documentation

1.6.1.39 SAP S/4HANA for procurement planning

Follow this procedure to set up SAP S/4HANA for procurement planning as a source system.

Prerequisites

You have technical credentials for SAP S/4HANA for procurement planning. See: Onboadring

Context

SAP S/4HANA for procurement planning is a cloud-based solution designed to help you plan procurement activities with regard to the time schedule, as well as the investment planning of items based on a central bill of material.

You can use Identity Provisioning to configure SAP S/4HANA for procurement planning as a source system where you can read **users** from and provision them to a target system.

> **Note**
>
> SAP S/4HANA for procurement planning does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.

2. Add *SAP S/4HANA Procurement Planning* as a source system. See: Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API of your SAP S/4HANA for procurement planning system without path information. For example: `https://procplanning-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP S/4HANA for procurement planning system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP S/4HANA for procurement planning system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://procplansecurity.authentication.eu10.hana.ondemand.com/oauth/token**
(Optional) `s4hana.pp.user.filter`	When specified, only those SAP S/4HANA for procurement planning users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA for procurement planning* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP S/4HANA for Procurement Planning

Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP S/4HANA for procurement planning system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                 "sourcePath": "$.userName",
                 "targetPath": "$.userName",
                 "correlationAttribute": true
            },
            {
                 "sourcePath": "$.displayName",
                 "targetPath": "$.displayName"
            },
            {
                 "sourcePath": "$.active",
                 "targetPath": "$.active"
            },
            {
                 "sourcePath": "$.emails",
                 "targetPath": "$.emails",
                 "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            }
        ]
    }
}
```

5. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP S/4HANA for procurement planning – Product Page

1.6.1.40 SAP S/4HANA On-Premise

Follow this procedure to set up SAP S/4HANA on-premise (also valid for SAP S/4HANA Cloud, private edition) as a source system.

Prerequisites

> **Note**
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have technical credentials (user and password) for SAP S/4HANA on-premise.
- The SAP S/4HANA on-premise system is version **1809** or higher.
- You have configured your SOA Manager to directly call the following Web services:
  - **ManageBusinessUserIn**
  - **QueryBusinessUserIn**

  For more information, see: Setting Up SOA Manager.

Context

You can use Identity Provisioning to configure SAP S/4HANA on-premise as a source system where you can read **business users** (employee, collaboration user, contingent worker, and resource) from and provision them to a target system.

In SAP S/4HANA, a business user is defined as a natural person who is represented by a business partner and a link to a user in the system. Actually, the business user is an AS ABAP (SU01) user who also has a one-to-one relation to a corresponding business partner. For more information on the identity model for business users, see SAP Note 2570961.

SAP S/4HANA on-premise supports reading of users with *User UUID* attribute which is generated by Identity Authentication at user creation. The attribute mapping is handled by the default transformation of SAP AS ABAP connector. Therefore, in order to read a user with *User UUID* from S/4HANA on-premise, the user should first be created (provisioned) in AS ABAP and then linked to its corresponding business user in S/4HANA on-premise. For more information, see: SAP Application Server ABAP [page 628].

Reading of **roles** (considered as *groups*) is also handled by the default transformation SAP AS ABAP connector.

Procedure

1. Open the Cloud Connector to add an access control system mapping for **SAP S/4HANA On-Premise**. This is needed to allow the Identity Provisioning service to access SAP S/4HANA On-Premise as a back-end system on the intranet. To learn how, see: Configure Access Control (HTTP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *SAP S/4HANA On-Premise* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP S/4HANA On-Premise system.
`ProxyType`	Enter: *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user for SAP S/4HANA On-Premise.
`Password`	(Credential) Enter the password for the SAP S/4HANA On-Premise technical user.
`s4hana.onprem.skip.read.archived`	In the event of archived (disabled) entities in a source SAP S/4HANA On-Premise system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd*
(Optional) `s4hana.onprem.sap-client`	Use this property if you want to specify a particular AS ABAP client to use as the **sap-client** URL parameter. If this property is not specified, the URL will open your default AS ABAP client. To learn more, see: Specifying the Client For more information about **sap-client**, see: SAP URL Parameters

Property Name	Description & Value
(Optional)`CloudConnectorLocationId`	Relevant when the `ProxyType` property is set to *OnPremise*. Use it in case your SAP Business Technology Platform account uses more than one Cloud Connector or when the Cloud Connector uses `LocationID`.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*OnPremise*

`URL`=*http://aaa777.myhost:1234*

`User`=*MYS4HANAUSER*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`s4hana.onprem.skip.read.archived`=*true*

`s4hana.onprem.sap-client`=*101*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA On-Premise* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in SAP S/4HANA On-Premise. For more information, see:

   Manage Transformations [page 2439]

   APIs for Business User Management

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "($.validityPeriod.startDate <= '${currentDate}') &&
($.validityPeriod.endDate > '${currentDate}')",
    "mappings": [
      {
        "sourcePath": "$.personID",
        "targetVariable": "entityIdSourceSystem"
      },
```

```
        {
          "sourcePath": "$.personalInformation.firstName",
          "targetPath": "$.name.givenName",
          "optional": true
        },
        {
          "sourcePath": "$.personalInformation.lastName",
          "targetPath": "$.name.familyName",
          "optional": true
        },
        {
          "sourcePath": "$.personalInformation.middleName",
          "targetPath": "$.name.middleName",
          "optional": true
        },
        {
          "sourcePath": "$.personalInformation.personFullName",
          "targetPath": "$.name.formatted",
          "optional": true
        },
        {
          "sourcePath": "$.personalInformation.nickName",
          "targetPath": "$.nickName",
          "optional": true
        },
        {
          "sourcePath": "$.userAssignment.userID",
          "targetPath": "$.userName",
          "optional": true,
          "correlationAttribute": true
        },
        {
          "constant": true,
          "targetPath": "$.active"
        },
        {
          "sourcePath": "$.workplaceInformation.emailAddress",
          "targetPath": "$.emails[0].value",
          "optional": true,
          "correlationAttribute": true
        },
        {
          "sourcePath": "$.PersonExternalID",
          "optional": true,
          "correlationAttribute": true
        },
        {
          "type": "valueMapping",
          "sourcePaths": [
            "$.businessPartnerRoleCode"
          ],
          "targetPath": "$.userType",
          "defaultValue": "Employee",
          "valueMappings": [
            {
              "key": [
                "BUP003"
              ],
              "mappedValue": "Employee"
            },
            {
              "key": [
                "BBP005"
              ],
              "mappedValue": "Contingent Worker"
            },
            {
              "key": [
```

```
              "BUP012"
            ],
            "mappedValue": "Collaboration User"
          },
          {
            "key": [
              "WFM001"
            ],
            "mappedValue": "Resource"
          }
        ]
      }
    ]
  }
}
```

6. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Maintain Collaboration Users

1.6.1.41 SAP SuccessFactors

Follow this procedure to set up SAP SuccessFactors as a source system.

Prerequisites

- You are using **SAP SuccessFactors HCM Suite OData API**
  You have created a technical user with permissions to **call** the SAP SuccessFactors HCM Suite OData API and to **export** employee data from the SAP SuccessFactors system. For more information, see Permissions and Setting Up an API User for Sync Jobs in SAP SuccessFactors. The following permissions are required:
  - *Manage User* > *Employee Export*

- *Manage User* > *User Account OData API Entity*
- *Manage Integration Tools* > *Allow Admin to Access OData API*
- *Manage Role-Based Permission Access* > *Role-Based Permission Admin*

- You are using **SAP SuccessFactors Workforce SCIM API**
  Consumers of the SAP SuccessFactors Workforce SCIM API can either create a technical user and assign the necessary permissions, or use the predefined technical user with built-in permissions for communication between SAP SuccessFactors and Identity Provisioning using certificate authentication. For more information, see Upgrade to X.509 Certificate-Based Authentication for Incoming Calls and Permissions.

Context

Companies that manage their employees using SAP SuccessFactors HCM Suite can use the Identity Provisioning service to automatically create accounts for these employees and manage their permissions for the cloud applications. When the hiring process of a new employee is completed in the SAP SuccessFactors HCM solution, a user record with the employee identity data is created in the SAP SuccessFactors system. The Identity Provisioning service can use this data for the identity and authorization provisioning processes.

SAP SuccessFactors provides two APIs for its integration with Identity Provisioning: SAP SuccessFactors HCM Suite OData API and SAP SuccessFactors Workforce SCIM API. The value of `sf.api.version` property controls which API you use.

- When the value is set to **`1`**, or the property is not defined - SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. This is the default value. SAP SuccessFactors source systems created before the introduction of `sf.api.version` property, use OData API.
- When the value is set to **`2`** - SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used. For more information on how to update to version 2, see Update Connector Version [page 2424].

Identity Provisioning supports reading of SAP SuccessFactors users, as well as static and dynamic groups of type Permission.

When users from SAP SuccessFactors source system are provisioned to Identity Authentication target system, newly created and updated users get the *userUUID* attribute generated by Identity Authentication. The Identity Provisioning in its turn sends the *userUUID* back to SAP SuccessFactors to update the users.

To create SAP SuccessFactors as a source system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP SuccessFactors* as a source system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP SuccessFactors and configure the authentication method (basic or certificate-based).

> ### Note
>
> We recommend that you use certificate-based authentication.

a. In your newly added SAP SuccessFactors source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

   Skip this step if you use basic authentication. The next steps are performed in SAP SuccessFactors Admin Center and are relevant for certificate-based authentication only.

b. Login to SAP SuccessFactors and go to *Admin Center*. Follow the procedure described in Upgrade to X.509 Certificate-Based Authentication for Incoming Calls.

   Make sure you select *Identity Provisioning Service* in the *Integration Name* field.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value

URL	Specify the URL to your SAP SuccessFactors API.
	
	For example:
	• For version 1:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com/odata/v2`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com/odata/v2`**
	• For version 2:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com`**
	
	To see the list of all SAP SuccessFactors data centers, see: SAP SuccessFactors API Reference Guide (OData V2): List of SAP SuccessFactors API Servers and System for Cross-domain Identity Management for Workforce in SuccessFactors

`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
(Optional) `sf.api.version`	Handles the version of the API which is consumed by the SAP SuccessFactors system. sf.user.attributes.expand **Possible values:** • *1* - Indicates that SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. • *2* - Indicates that SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used. Default value: *1*

Property Name	Description & Value
`User`	Valid if *BasicAuthentication* Enter the *userID* of your SAP SuccessFactors technical user in the following format: is configured as authentication method.**<user_ID>@<company_ID>**
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the password for your SAP SuccessFactors technical user.
`sf.company.id`	Valid if *ClientCertificateAuthentication* is is configured as authentication method. Enter the Company ID of your SAP SuccessFactors system. The Company ID is a short string of characters that identifies each SAP SuccessFactors system. It is like a username for your organization. All users of the same system share the same Company ID.

Property Name	Description & Value
`sf.user.attributes`	Default property. It's a string representing a comma-separated list of user attributes that have to be loaded (read) from SAP SuccessFactors. You can leave the default property value (all listed attributes), leave only some of them, or add some more. **Note** If you want to add more attributes, make sure you have added: • the relevant extra attributes to the value of this property, separated by commas • extra mappings for these attributes in the *user* transformation • extra mappings for these attributes in the write transformation of the relevant target system **→ Remember** • Always make sure that attribute `lastModifiedDateTime` is in the list of values. If you delete it (don't specify it), the provisioning from SAP SuccessFactors will fail. • If a user in SAP SuccessFactors is missing the `lastModifiedDateTime` attribute, it will break the provisioning. As a solution, you can exclude such users from the provisioning – either by using the `sf.user.filter` property, or by setting a condition in the transformation logic. **Connector version**: SAP SuccessFactors version 1

Property Name	Description & Value
(Optional) `sf.user.attributes.expand`	This property reads additional user data related to *complex (navigation) attributes*, which are specified in `sf.user.attributes`. Default value: *personKeyNav,personKeyNav/userAccountNav* **Note** If you want to add more complex attributes, enter the correct "paths" to them, specifying all parent attribute levels. For example, if you want to read information about user's skills and competency, add *positionSkillMappings/skill*. In this case, make sure you have added: • **positionSkillMappings** to the value of property `sf.user.attributes` • a relevant mapping for this attribute in the *user* transformation • a relevant mapping for this attribute in the write transformation of the relevant target system **Connector version**: SAP SuccessFactors version 1
(Optional) `sf.user.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. Use this property to filter users from SAP SuccessFactors. The filter obtains values as described in the OData 2.0 syntax, except any statements with attribute `lastModifiedDateTime`. Find below example syntax for filtering users depending of the API version: • OData API - **`username eq 'cbraun'`** • SCIM API - **`userName eq "cbraun"`** To learn more, see: • OData version 2 → **4.5. Filter System Query Option ($filter)**. • SAP SuccessFactors API Reference Guide (OData V2) • SAP SuccessFactors Workforce SCIM API and System for Cross-domain Identity Management for Workforce in SuccessFactors

Property Name	Description & Value
(Optional) `sf.user.read.deactivatedafter`	This property filters SAP SuccessFactors inactive users from a particular date on. It is an optional property which does not appear by default at system creation. It accepts a value in the **`yyyy-MM-dd`** format. For example: **`2023-07-17`** The `sf.user.read.deactivatedafter` property works together with the `sf.user.filter` property which is added at system creation with the default value: *active eq true*. Using it can further narrow down the filtering results. To filter active users along with inactive ones from a particular date on, the following configuration must be in place: • Set the `sf.user.read.deactivatedafter` value to a date in the expected format. For example: *2023-07-17* • `sf.user.filter` = *active eq true* As a result, Identity Provisioning reads SAP SuccessFactors active users and the users set to inactive from that date on using the 2023-07-17T00:00:00Z date-time format. Depending on the value you define for `sf.user.filter`, expect the following results: • `sf.user.filter` = *active eq false* All inactive users will be returned. • `sf.user.filter` = *active eq false and userName sw "Test_"* All inactive users with username starting with Test_ will be returned. **Note** When you filter by `sf.user.filter` = *active eq false* along with the property `sf.user.read.deactivatedafter`, the users that match the two critera will be read twice. • `sf.user.filter` = *active eq true and userName sw "Test_"* Inactive users from the provided date on and all active users with username starting with Test_ will be returned.

Property Name	Description & Value
	Connector version: SAP SuccessFactors version 2
(Optional) `sf.group.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. Use this property to filter dynamic groups from SAP SuccessFactors. The filter obtains values as described in the OData 2.0 syntax, except any statements with attribute `lastModifiedDateTime`. To learn more, see: • OData version 2 → **4.5. Filter System Query Option ($filter)** • SAP SuccessFactors API Reference Guide (OData V2) → **DynamicGroup** • SAP SuccessFactors Workforce SCIM API and System for Cross-domain Identity Management for Workforce in SuccessFactors
(Optional) `sf.group.prefix`	This property distinguishes SAP SuccessFactors groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SF_** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP SuccessFactors source system and will be provisioned to the target system with the following name pattern: **SF_<GroupDisplayName>**. This way SAP SuccessFactors groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP SuccessFactors groups will be read and provisioned to the target system with their actual display names. **Connector version**: SAP SuccessFactors version 2
(Optional) `sf.page.size`	Defines the paging size. • Default value: **100** • Maximum value: **1000** **Connector version**: SAP SuccessFactors version 1

Property Name	Description & Value
(Optional)`sf.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 100. To read more than 100 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **Connector version**: SAP SuccessFactors version 2

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination (configuration):

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://apitest.successfactors.com/odata/v2*

`User`=*sfsf_admin@mycompany.com*

`Password`=**********

`sf.user.attributes`=*userId,username,status,email,lastName,firstName,lastModifiedDateTime,personKeyNav,positionSkillMappings*

=*personKeyNav,personKeyNav/userAccountNav,positionSkillMappings/skill*

`sf.user.filter`=*department ne 'Manufacturing'*

`sf.group.filter`=*groupType eq 'permission'*

`sf.page.size`=*70*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   When the SAP SuccessFactors system is configured as a source, the Identity Provisioning service will read all the attributes of the user records supported by the SAP SuccessFactors API.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors. For more information, see:

Manage Transformations [page 2439]

SAP SuccessFactors HCM Suite OData API

SAP SuccessFactors Workforce SCIM API

Default transformation for SAP SuccessFactors HCM Suite OData API version 1:

Code Syntax

```
// The value of entityIdSourceSystem is used for storing the unique ID of
each user.
// You can change the default source attribute perPersonUuiD, but make
sure the new source attribute is also unique.
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.personKeyNav.perPersonUuid",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "constant": false,
        "targetPath": "$.active"
      },
      {
        "condition": "$.personKeyNav.userAccountNav.accountStatus
=='ACTIVE'",
        "constant": true,
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.personKeyNav.userAccountNav.username",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.username",
        "optional": true,
        "correlationAttribute": true
      },
      {

        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%sf.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%sf.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members"
      }
    ]
  }
}
```

> ### Note
>
> When SAP SuccessFactors users are provisioned to Identity Authentication, the service generates a user UUID for every newly created user. Within the same provisioning job, Identity Provisioning returns the user UUID back to SAP SuccessFactors and updates the *sapGlobalUserId* attribute.
>
> Identity Provisioning updates *sapGlobalUserId* when its value is **`null`** or when its value already exists. The latter is valid in cases where, for example, a user is deleted in the Identity Authentication target system and after running a Resync Job, the deleted user is created again. A new user UUID is generated which updates the old value in SAP SuccessFactors.
>
> Returning the user UUID back to SAP SuccessFactors and updating the *sapGlobalUserId* attribute is supported for standard and real-time provisioning scenarios. It is also supported in bulk scenarios, when bulk operations are enabled on the Identity Authentication target system.
>
> In case you encounter error **statusCode 432** during userUUID synchronization, see: Guided Answers: Error statusCode: 432

6. Now, add a target system to provision users into it. Choose from: Target Systems [page 936]

> ⚠ Caution
>
> The **email** attribute is not unique for *SAP SuccessFactors* but it's unique for systems like *Identity Authentication* or *SAP Analytics Cloud*. That's why, if you provision users to any of these systems, make sure that there are no *SAP SuccessFactors* users with duplicate e-mails. If there are such, then in the target system all affected users will be created as a single user, with merged user data.
>
> To learn more, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

(Guided Answers) Multiple Users from SAP SuccessFactors Are Created as One in Identity Authentication

1.6.1.42 SAP SuccessFactors Employee Central Payroll

Follow this procedure to set up SAP SuccessFactors Employee Central Payroll as a source system.

Context

SAP SuccessFactors Employee Central Payroll is a cloud product for payroll processing. It's a service offering where SAP SuccessFactors Employee Central is used for maintenance of core HR master data and SAP HCM Payroll system hosted in an SAP or Hyperscaler data center is used for payroll.

You can use Identity Provisioning to configure SAP SuccessFactors Employee Central Payroll as a source system where you read users and groups from and then provision them to a target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP SuccessFactors Employee Central Payroll* as a source system. See: Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP SuccessFactors Employee Central Payroll and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP SuccessFactors Employee Central Payroll source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next step is performed in SAP SuccessFactors Employee Central Payroll backend system and is relevant for both basic and certificate-based authentication.

   b. For certificate-based authentication, import the certificate generated in the Identity Provisioning UI in your SAP SuccessFactors Employee Central Payroll system, as described in Prerequisite: Finding the Access URL → step 5.

      For basic authentication, provide *User* and *Password*, as described in Prerequisite: Finding the Access URL → step 5.

   c. Save your changes.
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
URL	Enter the URL to your SAP SuccessFactors Employee Central Payroll system. For more information, see Prerequisite: Finding the Access URL → step 8.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication* For more information, see Prerequisite: Finding the Access URL → step 5.

Property Name	Value
`User`	Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`ecp.sap-client`	Enter the SAP client number (a three-digit number) of your SAP SuccessFactors Employee Central Payroll system. For example: **`102`**
(Optional) `ecp.user.filter`	When specified, only those SAP SuccessFactors Employee Central Payroll users matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *userName eq "JohnSmith"* • Value = *userName sw "J"* • Value = *emails.value eq "john.smith@example.com"*
(Optional) `ecp.group.filter`	When specified, only those SAP SuccessFactors Employee Central Payroll groups matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *displayName eq "ProjectTeam1"* • Value = *displayName sw "P"*

Property Name	Value
(Optional) `ecp.group.prefix`	This property distinguishes SAP SuccessFactors Employee Central Payroll groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`ECP_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP SuccessFactors Employee Central Payroll source system and will be provisioned to the target system with the following name pattern: **`ECP_<GroupDisplayName>`**. This way SAP SuccessFactors Employee Central Payroll groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP SuccessFactors Employee Central Payroll groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Employee Central Payroll* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – the behavior of the default transformation logic is to read all user attributes from the source SAP SuccessFactors Employee Central Payroll system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   > ### Note
   >
   > When configuring SAP SuccessFactors Employee Central Payroll as a source system, there may be a mismatch between optional user attributes in the source system and required user attributes in the target system. For example, the email is an optional attribute in SAP SuccessFactors Employee Central Payroll but a required one in Identity Authentication. In such cases, you need to review and adapt your source and/or target system transformations and configurations to reflect your needs.

   Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
              "sourcePath": "$.name.givenName",
              "targetPath": "$.name.givenName",
              "optional": true
            },
            {
              "sourcePath": "$.name.familyName",
              "targetPath": "$.name.familyName",
              "optional": true
            },
            {
              "sourcePath": "$.name.middleName",
              "targetPath": "$.name.middleName",
              "optional": true
            },
            {
                "sourcePath": "$.nickName",
                "targetPath": "$.nickName",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true
            },
            {
                "sourcePath": "$.phoneNumbers",
                "targetPath": "$.phoneNumbers",
                "optional": true,

                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%ecp.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%ecp.group.prefix%"
                    }
                ]
            },
            {
              "sourcePath": "$.displayName",
              "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "optional": true,
                "preserveArrayWithSingleElement": true
            }
        ]
```

```
    }
}
```

6. Add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Identity Provisioning for Employee Central Payroll

1.6.1.43 SAP SuccessFactors Incentive Management

Follow this procedure to set up a source connector for SAP SuccessFactors Incentive Management, formerly known as SAP Commissions.

Prerequisites

You have technical user credentials for an SAP SuccessFactors Incentive Management system with read and write access permissions.

Context

After fulfilling the prerequisites, follow the procedure below to add a source system for SAP SuccessFactors Incentive Management to read users and user assignments to groups. This source system consumes SCIM 2.0 API provided by SAP SuccessFactors Incentive Management.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP SuccessFactors Incentive Management* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP SuccessFactors Incentive Management SCIM API portal.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP SuccessFactors Incentive Management system.
`Password`	(Credential) Enter the password for your SAP SuccessFactors Incentive Management user.

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

   Exemplary destination:

   `Type`=*HTTP*

   `Authentication`=*BasicAuthentication*

   `ProxyType`=*Internet*

   `URL`=*https://mycommissions.callidus.run/CallidusPortal*

   `User`=*MyCommissionsUser*

   `Password`=**********

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Incentive Management* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see:

   Manage Transformations [page 2439]

   SAP SuccessFactors Incentive Management REST API

The behavior of the default transformation logic is to read all user attributes from the source SAP SuccessFactors Incentive Management system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "targetVariable": "entityIdSourceSystem",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.id",
        "targetPath": "$.id",
        "optional": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificPrefix",
        "targetPath": "$.name.honorificPrefix",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "optional": true,
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
```

```
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.timezone",
        "optional": true,
        "targetPath": "$.timezone"
      },
      {
        "sourcePath": "$.addresses",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.addresses"
      },
      {
        "sourcePath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups"
      },
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.locale",
        "optional": true,
        "targetPath": "$.locale",
        "functions": [
          {
            "type": "substring",
            "beginIndex": 0,
            "endIndex": 2
          }
        ]
      }
    ]
  }
}
```

5. Now, add a target system to provision users and their group assignments to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP SuccessFactors Incentive Management: Integration with SAP IdP

1.6.1.44 SAP SuccessFactors Learning

Follow this procedure to set up SAP SuccessFactors Learning as a source system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the API of SAP SuccessFactors Learning for reading user information.

Context

SAP SuccessFactors Learning is a learning solution which helps organizations to improve employee skills and talent management, align learning outcomes with performance goals, boost compliance, and train external audiences.

You can use Identity Provisioning to configure SAP SuccessFactors Learning as a source system where you can read **users** from and provision them to a target system.

When users from SAP SuccessFactors Learning source system, are provisioned to Identity Authentication target system, all newly created users get the *userUUID* attribute generated by Identity Authentication. The Identity Provisioning in its turn sends the *userUUID* back to SAP SuccessFactors Learning to update the users.

> ⚠ Restriction
>
> Reading *groups* is not supported.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SAP SuccessFactors Learning* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
Type	Enter: *HTTP*

Property Name	Value
`URL`	Specify the URL to the API of your SAP SuccessFactors Learning system. It follows the pattern: `https://<root URL>/learning/public-api/rest/admin/Integration.svc/ias`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user ID for SAP SuccessFactors Learning.
`Password`	(Credential) Enter the password for the SAP SuccessFactors Learning technical user. For more information, see Learning Technical User.
(Optional) `lms.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** • *userName eq "testName"* • *externalID eq "testID"* • *active eq "true"* • *sourceSystem eq "Learning"* - indicates that the user is created directly in SAP SuccessFactors Learning with no involvement of Identity Provisioning. • *sourceSystem eq "Identity Provisioning"* - indicates that the user is created in SAP SuccessFactors Learning by Identity Provisioning.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Learning* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   The behavior of the default transformation logic is to read all user attributes from the source SAP SuccessFactors Learning system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   You can change the default transformation mapping rules depending on your setup of entities in your SAP SuccessFactors Learning. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP SuccessFactors Learning

   Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.schemas",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.externalId",
        "optional": true,
        "targetPath": "$.externalId"
      },
      {
        "sourcePath": "$.locale",
        "optional": true,
        "targetPath": "$.locale"
      },
      {
        "sourcePath": "$

        "optional": true,
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['siteID']"
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['sourceSystem']",
        "optional": true,
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['sourceSystem']"
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['applicationID']",
        "optional": true,
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['applicationID']"
      },
```

```
      {
"sourcePath": "$['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']
['customColumns']['110']",
        "optional": true,
        "targetPath": "$.custom-column-path-1"
      },
      {
"sourcePath": "$['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']
['customColumns']['120']",
        "optional": true,
        "targetPath":  "$.custom-column-path-2"
      },
      {
        "sourcePath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.phoneNumbers"
      },
      {
        "sourcePath": "$.emails",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.emails"
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active"

      }
    ]
  }
}
```

→ Tip

Your main scenario with this source connector might be provisioning SAP SuccessFactors Learning users to SAP Cloud Identity Service – Identity Authentication. In this case, you can add the following **condition** at the beginning of the "user" resource since *emails* and *name.familyName* are mandatory attributes for Identity Authentication users.

```
{
  "user": {
"condition": "($.emails[0].value EMPTY false) && ($.name.familyName EMPTY
false)",
    "mappings": [
      ...
```

ⓘ Note

When SAP SuccessFactors Learning users are provisioned to Identity Authentication, the service generates a user UUID for every newly created user. Within the same provisioning job, Identity Provisioning returns the user UUID back to SAP SuccessFactors Learning and updates the *userUUID* attribute.

> Identity Provisioning updates *userUUID* when its value is *null* or when its value already exists. The latter is valid in cases where, for example, a user is deleted in the Identity Authentication target system and after running a Resync Job, the deleted user is created again. A new user UUID is generated which updates the old value in SAP SuccessFactors Learning.
>
> Returning the user UUID back to SAP SuccessFactors Learning and updating the *userUUID* attribute is supported for standard and real-time provisioning scenarios. It is also supported in bulk scenarios, when bulk operations are enabled on the Identity Authentication target system.

5. Now, add a target system to provision users to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP SuccessFactors Learning

1.6.1.45 Sales Cloud – Analytics & AI

Follow this procedure to set up Sales Cloud – Analytics & AI as a source system.

Prerequisites

You have technical user credentials for an Sales Cloud – Analytics & AI (in short, *SCAAI*) system with read and write access permissions.

Context

After fulfilling the prerequisites, follow the procedure to add a source system for Sales Cloud – Analytics & AI to read users and user assignments to groups. This source system consumes SCIM 2.0 API provided by SCAAI.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Sales Cloud – Analytics & AI* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API portal of your SCAAI system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SCAAI system.
`Password`	(Credential) Enter the password for your SCAAI user.
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your SCAAI administrator.
(Optional)`sales.cloud.analytics_ai.group.filter`	Enter a group filter criteria, according to the API syntax of SCAAI. For example: **displayName eq "first_group"**
(Optional)`sales.cloud.analytics_ai.user.filter`	Enter a user filter criteria, according to the API syntax of SCAAI. For example: **externalId eq "John123"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=http://myscaai:8080/scim_services
User=MySCAAIUser
Password=************
OAuth2TokenServiceURL=http://myscaai:8080/gateway_services/api/auth/ips/token
```

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Sales Cloud – Analytics & AI* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCAAI system. For more information, see Manage Transformations [page 2439].

   The behavior of the default transformation logic is to read all user attributes from the source SCAAI system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity.

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.groups",
                "targetPath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "optional" : true
            },
            {
                "type": "remove",
                "targetPath": "$.groups[*].display"
            },
```

```
            {
                "type": "remove",
                "targetPath": "$.groups[*].ref"
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
            },
            {
                "optional": true,
                "preserveArrayWithSingleElement": true,
                "sourcePath": "$.members",
                "targetPath": "$.members"
            },
            {
                "type": "remove",
                "targetPath": "$.members[*].$ref"
            },
            {
                "type": "remove",
                "targetPath": "$.members[*].display"
            }
        ]
    }
}
```

5. Now, add a target system to provision users and their group assignments to it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.46 Cloud Foundry UAA Server

Follow this procedure to set up the Cloud Foundry UAA server as a source system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Jam Collaboration** and **SAP Identity Access Governance** bundle options.

- You have technical user credentials for a Cloud Foundry system with read access permissions.
  In case OAuth is used for authentication, client ID and secret are required when creating a destination for access token retrieval. You need Cloud Foundry UAA version **4.2** or higher.
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need to do this only if the Cloud Foundry UAA server is exposed in a private corporate network. For more information, see Cloud Connector.

Context

User Account and Authentication Service (UAA) is an OAuth2 server that you can use for centralized identity management. It owns the user accounts and authentication sources, and supports standard protocols (such as *SAML*, *LDAP*, and *OpenID Connect*) to provide SSO and delegated authorization to Web applications. For more information, see Cloud Foundry: Overview .

Cloud Foundry UAA is responsible for the SAP ID service to create and manage platform users (platform administrators and platform developers) in Cloud Foundry.

> → Tip
>
> This connector is meant for reading users and groups from **general** Cloud Foundry systems (they could be non-SAP ones). If you want to trigger provisioning of entities from SAP Business Technology Platform Cloud Foundry applications, you'd better use SAP BTP XS Advanced UAA (Cloud Foundry) [page 686] source system.

These source systems consume SCIM 1.1 API provided by Cloud Foundry UAA.

> → Remember
>
> You can read Cloud Foundry users and groups on **application** level only. You cannot read or manage them on a *subaccount* level.

Follow the steps below to create Cloud Foundry UAA as a source system to read users and groups, which can then be provisioned to a certain target system.

Procedure

1. (Optional) If the Cloud Foundry UAA server is exposed in a private corporate network, add an access control system mapping in Cloud Connector. For more information, see Configure Access Control (HTTP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *Cloud Foundry UAA Server* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the Cloud Foundry UAA SCIM API. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	As you need to make OAuth authentication to the UAA system, enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`User`	Enter the OAuth client ID of the Cloud Foundry UAA technical user.
`Password`	(Credential) Enter the OAuth client secret of the technical user.
`uaa.origin`	Enter the location of your Cloud Foundry identity provider. If not sure about the value, ask your Cloud Foundry UAA administrator. The value of this property is a string, which will be used as the *origin* attribute in the system transformation.
`uaa.origin.filter.enabled`	This flag property depends on `uaa.origin`. Possible values: **true** or **false** • If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `uaa.origin`. • If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. • If set to *true* but the `uaa.origin` property is missing, the provisioning job will fail.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://api.authentication.hana.ondemand.com
OAuth2TokenServiceURL=https://MyCFaccount.authentication.hana.ondemand.com/oauth/token
User=MyCFuser
Password=************
uaa.origin=my_UAA_location
uaa.origin.filter.enabled=true
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Cloud Foundry UAA Server* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from a Cloud Foundry UAA entity to the intermediate Identity Provisioning representation.
   - **User offboarding** – If a user or group has been deleted from the Cloud Foundry UAA server, this change is recognized, and the user/group is deleted from the target system too.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Cloud Foundry UAA server. For more information, see:

   Manage Transformations [page 2439]

   Cloud Foundry UAA API: Users

   Cloud Foundry UAA API: Groups

   Default transformation:

   Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "correlationAttribute": true
```

```
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "optional": true,
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.groups",
        "targetPath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.verified",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.origin",
        "targetPath": "$.origin",
        "optional": true
      },
      {
        "sourcePath": "$.zoneId",
        "targetPath": "$.zoneId",
        "optional": true
      }
    ]
  },
  "group": {
    "mappings": [
      {
```

```
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "'%uaa.group.prefix%' !== 'null'",
            "function": "concatString",
            "prefix": "%uaa.group.prefix%"
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      },
      {
        "sourcePath": "$.description",
        "targetPath": "$.description",
        "optional": true
      },
      {
        "sourcePath": "$.zoneId",
        "targetPath": "$.zoneId",
        "optional": true
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      }
    ]
  }
}
```

6. Now, add a target system to which to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

Cloud Foundry UAA: Groups

1.6.1.47 Google G Suite

Follow this procedure to set up Google G Suite as a source system.

Prerequisites

1. Sign in to the Google API console (https://console.developers.google.com) and create a project.
2. Enable the Admin SDK. To do this, go to *Dashboard* > *ENABLE API* > *Admin SDK* > *ENABLE*.
3. Create a service account for your project. We recommend that you select *Enable G Suite Domain-wide Delegation* during the creation. If you skip this option, you can set it later. For more information, see Creating a service account .
4. Then, in the Google admin console (https://admin.google.com), a user with **Super Admin** role can delegate domain-wide authority to your service account. This way, it will have access to the Google Admin SDK on behalf of your user. For more information, see Delegating domain-wide authority .

> **Note**
>
> When specifying the scopes, the administrator has to enter the following:
>
> `https://www.googleapis.com/auth/admin.directory.user, https://www.googleapis.com/auth/admin.directory.group`

Context

A Google service account with delegated domain-wide authority is required for authentication and authorization of the Identity Provisioning service to G Suite domain. The authentication is based on OAuth 2.0 protocol with JSON Web Token (JWT). The private key for the signature is distributed by Google via one-time

downloadable JSON data, which is accessible by the domain administrator. The private key is encoded in PKCS8 format and is in the *private_key* field of the JSON data. For more information, see JSON Web Token (JWT) .

- When using it as a source system, you can read both users and groups from Google G Suite and provision them to any target system you have added in the Identity Provisioning user interface.
- When using it as a target system, you can write both users and groups, read from any source system you have added in the Identity Provisioning user interface. Google G Suite can automatically create accounts for your users in the Google Cloud Datastore.

The Identity Provisioning service supports user and group operations based on the following Google Directory API. See the table below.

User Operations	Group Operations
Create a user	Create a group
Retrieve a user	Retrieve a group's properties
Update a user	Update a group's properties
Delete a user	Delete a group

> ⚠ Caution
>
> You can only provision users whose e-mails are from verified domains.

If you have successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure below.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems* .
2. Add *Google G Suite* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*
URL	Specify the service URL: `https://www.googleapis.com/admin/directory`

Property Name	Description & Value
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication* The authentication type in use is actually **OAuth** with JWT. But for any provisioning system based on OAuth, **BasicAuthentication** is used along with the `OAuth2TokenServiceURL` additional property.
`User`	Enter the service account's ID. You can take it from the *"client_email"* field in the JSON data, downloaded during the setup of Google service account.
`Password`	(Credential) Enter the service account's private key, which represents a long string in PKCS8 format. You can take it from the *"private key"* field in the JSON data, downloaded during the setup of Google service account.
`OAuth2TokenServiceURL`	To make OAuth authentication to the Google G Suite system, enter the URL to the access token provider service. For more information, see Using OAuth 2.0 to Access Google APIs .
`jwt.subject`	Enter the Google G Suite user on behalf of which the Google Directory API is called. This user has been assigned the role **User Management Admin**. This property corresponds to "sub" claim in JWT being generated during access token request: JWT: "sub" (Subject) Claim
(Optional) `jwt.scope`	Enter space-separated Google Directory API authorization scopes. For example: **`https://www.googleapis.com/auth/admin.directory.user`**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary Configuration:

`ProxyType`=*Internet*

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`URL`=*https://www.googleapis.com/admin/directory*

`User`=*1234567890-compute@developer.gserviceaccount.com*

`Password`=*-----BEGIN PRIVATE KEY-----\n123ABCDEFG123456789...*

... /123456789ABCDEFG123=\n-----END PRIVATE KEY-----\n

`OAuth2TokenServiceURL`=*https://www.googleapis.com/oauth2/v4/token*

`jwt.subject`=*john.smith@me123.accounts.ondemand.com*

`jwt.scope`=*https://www.googleapis.com/auth/admin.directory.user*

---

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Google G Suite* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Transformation principles for the source system integration:

   - **Mapping logic** – The provisioning framework reads all attributes from the Google G Suite source system and transfers them to the intermediate JSON data, which then tries to create consistent records in the target system, using all the available attributes accepted by the target system API. When a required attribute is missing, the default transformation is designed with a condition that will exclude the inconsistent records.
   - **User off-boarding** – Identity Provisioning service is handling the deletion status of the users. When a user is deleted from Google G Suite, this deletion will be enforced into the target system as well.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Google G Suite. For more information, see:

   Manage Transformations [page 2439]

   Google Directory API: Users

   Google Directory API: Groups

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
```

```
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.primaryEmail",
                "targetPath": "$.emails[0].value",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.primaryEmail",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name",
                "targetPath": "$.name"
            },
            {
                "constant": true,
                "targetPath": "$.active"
            },
            {
                "condition": "$.suspended == true",
                "constant": false,
                "targetPath": "$.active"
            }
        ]
    },
      "group": {
        "ignore": true,
        "mappings": [
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.name",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.members[?((@.type == 'USER') && (@.status
== 'ACTIVE'))]",
                "targetPath": "$.members",
                "optional": true,
                "preserveArrayWithSingleElement": true
            },
            {
                "targetPath": "$.members[*].status",
                "type": "remove"
            },
            {
                "targetPath": "$.members[*].id",
                "type": "rename",
                "constant": "value"
            },
            {
                "constant": "display",
                "targetPath": "$.members[*].email",
                "type": "rename"
            },
            {
                "targetPath": "$.members[*].kind",
                "type": "remove"
            },
            {
```

```
                "targetPath": "$.members[*].etag",
                "type": "remove"
            },
            {
                "targetPath": "$.members[*].role",
                "type": "remove"
            }
        ]
    }
}
```

If the **displayName** attribute in the source system transformation does not provide group e-mails, you can modify the transformation the following ways:

- Map **email** to another attribute that contains a unique group e-mail.
- Concatenate the **displayName** attribute with your domain. For example:

Sample Code

```
        {
            "sourcePath": "$.displayName",
            "targetPath": "$.email",
            "scope": "createEntity",
            "functions": [
                {
                    "type": "concatString",
                    "suffix": "@test.myaccount.ondemand.com"
                }
            ]
        }
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.48 LDAP Server

Follow this procedure to set up LDAP Server as a source system.

Prerequisites

> **Note**
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo) or Cloud Connector (Cloud Foundry)
- **For tenants running on the infrastructure of SAP Cloud Identity Services**: You have a multi-environment subaccount in the Cloud Foundry region that maps the region of your Identity Authentication tenant and it is subscribed to the *Cloud Identity Services* application. For more information, see Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.
- You have the credentials of a technical user in the LDAP Server, which is used to call the LDAP Server API to read the users and their attributes.

Context

You can use LDAP Server to read entities from it and provision them to a target system. This scenario supports reading **users** and **groups**.

There are two versions of the LDAP Server connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on May 25, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
- When the value is set to *2* – LDAP Server API version 2 is used.
  This version of the connector comes with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
  Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
  After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
  For more information on how to update to LDAP Server connector version 2, see Update Connector Version [page 2424].

Procedure

1. Add an access control system mapping for the **LDAP Server** in the Cloud Connector. This is needed to allow the Identity Provisioning service to access the LDAP server as a back-end system on the intranet. For more information, see Configure Access Control (LDAP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *LDAP Server* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify the destination URL. It must be in the following format: `ldap://<external_host>:<external_port>`
`ldap.proxyType`	Enter: *OnPremise*
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.user`	Enter the *distinguishedName* of the technical LDAP user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the LDAP technical user.
`ldap.group.path`	Enter the complete path to the node containing the groups in the LDAP tree.
`ldap.user.path`	Enter the complete path to the users in the LDAP tree.
(Optional)`ldap.api.version`	Defines the version of LDAP Server API. **Possible values:** • **1** - Indicates that LDAP Server API version 1 is used. • **2** - Indicates that LDAP Server API version 2 is used. If the property is not defined - LDAP Server API version 1 is used.

Property Name	Description & Value
`ldap.user.attributes`	Shows which user attributes from the source system to be included in the LDAP read result (and respectively, in the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • LDAP Server version 1 version 1 - Even though you specified the attributes to be included in the LDAP read result, Identity Provisioning will return all attributes from the LDAP server. • LDAP Server version 2 - Only the specified attributes will be included in the LDAP server read result.
`ldap.group.attributes`	Shows which group attributes from the source system to be included in the LDAP read result (and respectively, in the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • LDAP Server version 1 - Even though you specified the attributes to be included in the LDAP read result, Identity Provisioning will return all attributes from the LDAP server. • LDAP Server version 2 - Only the specified attributes will be included in the LDAP server read result. If nothing is set, all attributes are included.

> → Remember
>
> We strongly recommend that you enter different paths for LDAP users and groups. That means, the value of `ldap.user.path` should be different than the value of `ldap.group.path`.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

The LDAP Server source system is created by default with the properties listed below:

Default LDAP Properties

```
ldap.user.attributes=
ldap.group.attributes=
ldap.user.object.class= inetOrgPerson
ldap.group.object.class= groupOfNames
ldap.group.uniquename.attribute= cn
ldap.member.uniquename.attribute=uid
ldap.attribute.group.id=cn
ldap.attribute.group.member= member
ldap.attribute.user.id= uid
ldap.attribute.dn=distinguishedName
ldap.user.filter=
ldap.group.filter=
ldap.page.size= 100
ldap.attribute.user.mail= mail
ldap.attribute.user.mobile=mobile
ldap.attribute.user.givenName= givenName
ldap.attribute.user.surname= sn
ldap.attribute.user.groups= memberOf
ldap.attribute.user.telephoneNumber= telephoneNumber
```

> ### Note
>
> The **ldap.attribute.*** properties are used as parameterized properties in the default transformation. That is, if a property used in the transformation doesn't have a value, the provisioning job will fail when the transformation is loaded on runtime and the property value is substituted.
>
> Also, you can change a property and use a new one (with a new name). In this case, you must replace the old property with the new one at all corresponding places in the transformation.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *LDAP Server* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your LDAP server. For more information, see Manage Transformations [page 2439].

Currently, the default read transformations of the two connector versions have no differences, so there is no need to update them.

Before the read transformation, the LDAP Server attributes are represented as arrays (single-element arrays, or multi-value arrays separated by comma (,)). After read transformation (in the intermediate JSON data), the attributes are in SCIM format. For more information, see the official documentation for LDAP Server schema attributes in the **Related Information** section.

> ### Note
>
> When a user is deleted from LDAP Server, the deletion status is considered by the Identity Provisioning service during the read processes. Depending on the offboarding handling of the users in the target system, the user can be deleted, or can be set to *inactive*.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [

/* The value of entityIdSourceSystem is used to store the unique ID of the
identity. You should not delete this statement.
You could exchange the default attribute, resolved from
ldap.attribute.user.id system property (which is used as a source) with
another one but make sure the new source attribute is unique as well. */
        {
            "sourcePath": "$.%ldap.attribute.user.id%[0]",
            "targetVariable": "entityIdSourceSystem",
            "correlationAttribute": true
        },

/* The value of the attribute resolved from ldap.attribute.user.id
system property is used also as userName value for the internal JSON
representation. */
        {
            "sourcePath": "$.%ldap.attribute.user.id%[0]",
            "targetPath": "$.userName",
            "correlationAttribute": true
        },

/* The constant urn:ietf:params:scim:schemas:core:2.0:User is required as
a value for the schemas definition in the Identity Authentication service
SCIM REST API. */
        {
            "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
            "targetPath": "$.schemas[0]"
        },

/* The value of the attribute resolved from ldap.attribute.user.mail
system property is used also as a first array value in the emails JSON
array. */
        {
            "sourcePath": "$.%ldap.attribute.user.mail%[0]",
            "targetPath": "$.emails[0].value",
            "optional": true,
```

```
            "correlationAttribute": true
        },

/* The value of the attribute resolved from ldap.attribute.user.givenName
system property is used for the name.givenName value in internal JSON
representation. */
        {
            "sourcePath": "$.%ldap.attribute.user.givenName%[0]",
            "targetPath": "$.name.givenName",
            "optional": true
        },

/* The value of the attribute resolved from ldap.attribute.user.surname
system property is used for the name.familyName value in internal JSON
representation. */
        {
            "sourcePath": "$.%ldap.attribute.user.surname%[0]",
            "targetPath": "$.name.familyName",
            "optional": true
        },

/* The attribute resolved from ldap.attribute.user.groups system property
is transformed by default into groups attribute of the SCIM internal
representation: */
        {
            "sourcePath": "$.%ldap.attribute.user.groups%",
            "preserveArrayWithSingleElement": true,
            "optional": true,
            "targetPath": "$.groups[?(@.value)]"
        },

        {
            "sourcePath": "$.%ldap.attribute.user.mobile%[0]",
            "optional": true,
            "targetPath": "$.phoneNumbers[0].value"
        },
        {
            "condition": "$.%ldap.attribute.user.mobile%.length() > 0",
            "constant": "mobile",
            "targetPath": "$.phoneNumbers[0].type"
        },
        {
            "sourcePath": "$.%ldap.attribute.user.telephoneNumber%[0]",
            "optional": true,
            "targetPath": "$.phoneNumbers[1].value"
        },
        {
            "condition": "$.%ldap.attribute.user.telephoneNumber%.length()
> 0",
            "constant": "work",
            "targetPath": "$.phoneNumbers[1].type"
        }
      ]
    },
      "group": {
        "ignore": true,
        "mappings": [
            {
                "sourcePath": "$.%ldap.attribute.group.id%[0]",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.%ldap.attribute.group.id%[0]",
                "targetPath": "$.displayName"
            },
```

```
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.%ldap.attribute.group.member%",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]"
            }
        ]
    }
}
```

As result of this mapping, this is how the data from LDAP Server looks like before and after the read transformation:

Transformation Snippet (from the user mapping)	Source JSON Data (as read from LDAP Server)	Intermediate JSON Data (as result from the transformation)
Sample Code `{ "user": { "mappings": [ ... { "sourcePath": "$.%ldap.attribute.user.groups%[0]", "preserveArrayWithSingleElement": true, "optional": true, "targetPath": "$.groups[?(@.value)]" }, ...`	Sample Code `... "memberOf": [ "SALES_US", "SALES_EU", "SALES_JA" ] …`	Sample Code `... "groups":[ { "value": "SALES_US" }, { "value": "SALES_EU" }, { "value": "SALES_JA" } ] …`

> **Note**
>
> By default, the **cn** attribute is returned for every read group. An administrator can change this behavior by setting the following properties:
>
> - `ldap.group.uniquename.attribute` – the value can be either the CN or the whole DN (**distinguishedName**) of the group.
> - `ldap.attribute.group.id` – the value can be CN or another attribute to be used as a group ID instead (for example, **displayName** or **description**).
>
> For more information about these properties, see: List of Properties [page 80]

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Connection Pooling Configuration

1.6.1.49 Microsoft Active Directory

Follow this procedure to set up Microsoft Active Directory as a source system.

Prerequisites

> **Note**
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have the credentials of a technical user in the Microsoft Active Directory, which is used to call the Microsoft Active Directory API to read the users and their attributes.

Context

You can configure Microsoft Active Directory (Microsoft AD) as a source system to read users, groups and permission assignments.

There are two versions of the Microsoft AD connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on June 19, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
  In this version, the `group members` attribute mapping in the proxy read transformation does not include `type` sub-attribute. In this case, all members are considered of type `User`, which is the sub-attribute fallback value. As a consequence, if the external system includes nested groups, they will not be handled properly.
- When the value is set to *2* – LDAP Server API version 2 is used.
  This version of the connector is with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
  Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
  After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
  In this version, the `group members` attribute mapping in the proxy read transformation is enhanced with `type` sub-attribute. The sub-attribute has two possible values – `User` and `Group`. This allows you to read and preserve nested groups.
  For more information on how to update to Microsoft Active Directory version 2, see Update Connector Version [page 2424].

Procedure

1. Add an access control system mapping for the **Microsoft Active Directory** in the Cloud Connector. This is needed to allow the Identity Provisioning service to access Microsoft AD as a back-end system on the intranet. For more information, see Configure Access Control (LDAP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *Microsoft Active Directory* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify a destination URL. It must be in the following format: `ldap://<ext_host>:<ext_port>`
`ldap.proxyType`	Enter: *OnPremise*

Property Name	Description & Value
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.attribute.user.id`	Default property, which denotes the ID of a user. By default, it's set to: *cn*
`ldap.attribute.group.id`	Default property, which denotes the ID of a group. By default, it's set to: *cn*
`ldap.attribute.dn`	Default property, which denotes the distinguished name of a user or a group. Only possible value: *distinguishedName*
`ldap.user`	Enter the *distinguishedName* or the *userPrincipalName* of the Microsoft AD technical user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the Microsoft AD technical user.
`ldap.group.path`	Enter the complete path to the node containing the groups in Microsoft AD.
`ldap.user.path`	Enter the complete path to the users in Microsoft AD.
`ldap.api.version`	Defines the version of LDAP Server API. **Possible values:** • **1** - Indicates that LDAP Server API version 1 is used. • **2** - Indicates that LDAP Server API version 2 is used. If the property is not defined - LDAP Server API version 1 is used.
`ldap.user.attributes`	Shows which user attributes from the source system to be included in the Microsoft AD read result (and respectively, in the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • Microsoft AD version 1 - Even though you specified the attributes to be included in the Microsoft AD read result, Identity Provisioning will return all attributes from the Microsoft AD. • Microsoft AD version 2 - Only the specified attributes will be included in the Microsoft AD read result. *sAMAccountName* is always included as mandatory user attribute for Microsoft AD version 2.

Property Name	Description & Value
`ldap.group.attributes`	Shows which group attributes from the source system to be included in the Microsoft AD read result (and respectively, in the intermediate JSON data). Separate the attributes by comma (,). **Possible values:** • Microsoft AD version 1 - Even though you specified the attributes to be included in the Microsoft AD read result, Identity Provisioning will return all attributes from the Microsoft AD. • Microsoft AD version 2 - Only the specified attributes will be included in the or Microsoft AD. If nothing is set, all attributes are included.
(Optional) `ad.group.flatten`	There are target systems that do not support nested groups (group structures). Therefore, if your Microsoft AD system contains such groups, they will not be resolved properly during the provisioning job. Such target systems are: • *SAP Jam Collaboration* • *Identity Authentication* To enable reading of group structures, you can use the `ad.group.flatten` property and set it to *true*. It will read the group structure recursively and will "flatten" it so that all users from all groups and subgroups will be resolved and written in the target system as members of the main parent group. **Note** Performance might be affected when `ad.group.flatten` is set to true and group structure is very complex (contains a lot of nested groups). For best results, we recommend you also set the system property `ldap.group.filter` whose value is one or multiple Microsoft AD parent groups. For example, if a parent group is named **Canteen**, the property should be set as: `ldap.group.filter`= *(cn=Canteen)* See the example below with multiple parent groups.

Example for a destination or a set of properties:

```
Type=LDAP
Name=MyADDestination
ldap.user=john.smith@some.dummy.domain.com
ldap.password=********
ldap.attribute.user.id=cn
ldap.attribute.group.id=cn
ldap.attribute.dn=distinguishedName
ldap.url=ldap://abcd:123
ldap.proxyType=OnPremise
ldap.authentication=BasicAuthentication
ldap.group.path=OU=Groups,OU=IAS,DC=global,DC=corp,DC=mycompany
ldap.user.path=OU=Users,OU=IAS,DC=global,DC=corp,DC=mycompany
ldap.group.filter=(|(cn=Canteen)(cn=Finance)(cn=Support_Team))
ad.group.flatten=true
```

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Active Directory* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Before the read transformation, the Microsoft Active Directory attributes are represented as arrays – single-element arrays, or multi-value arrays separated by comma (,). After the read transformation (in the intermediate JSON data), the attributes are in SCIM format. For more information about Microsoft AD schema attributes, see the **Related Information** section.

   Currently, the default read transformations of the two connector versions have no differences, so there is no need to update them.

   You can change the default transformation mapping rules to reflect your current setup of entities in Microsoft Active Directory. For more information, see:

   Manage Transformations [page 2439]

   Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.%ldap.attribute.user.id%[0]",
        "targetVariable": "entityIdSourceSystem",
        "correlationAttribute": true
      },
      {
        "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
        "constant": "",
        "functions": [
          {
            "function": "concatString",
            "prefix": "(?i)cn=.*?,(.*?)",
            "suffix": ",%ldap.user.path%"
          }
        ],
        "targetVariable": "nestedPathRegex"
      },
// If a user is not a direct member of the configured user base path,
then function getMatchedRegexGroup extracts the nested path from the
distinguishedName of this user,
// and maps the nested path to attribute
['urn:sap:cloud:scim:schemas:extension:ad:2.0:User']['nestedPath']
      {
        "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
        "sourcePath": "$.%ldap.attribute.user.id%[0]",
        "functions": [
          {
            "function": "getMatchedRegexGroup",
            "regex": "${nestedPathRegex}",
            "groupIndex": 1
          }
        ],
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:User']['nestedPath']",
        "defaultValue": ""
      },
      {
        "sourcePath": "$.sAMAccountName[0]",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.displayName[0]",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.mail[0]",
        "targetPath": "$.emails[0].value",
        "optional": true,
        "correlationAttribute": true
      },
      {
```

```
        "sourcePath": "$.givenName[0]",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.sn[0]",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.memberOf",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups[?(@.value)]"
      },
      {
        "sourcePath": "$.mobile[0]",
        "optional": true,
        "targetPath": "$.phoneNumbers[0].value"
      },
      {
        "condition": "$.mobile.length() > 0",
        "constant": "mobile",
        "targetPath": "$.phoneNumbers[0].type"
      },
      {
        "sourcePath": "$.telephoneNumber[0]",
        "optional": true,
        "targetPath": "$.phoneNumbers[1].value"
      },
      {
        "condition": "$.telephoneNumber.length() > 0",
        "constant": "work",
        "targetPath": "$.phoneNumbers[1].type"
      }
    ]
  },
  "group": {
    "ignore": true,
    "mappings": [
      {
        "sourcePath": "$.%ldap.attribute.group.id%[0]",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "condition": "('%ldap.attribute.group.id%' ==
'%ldap.attribute.dn%')",
        "constant": "",
        "functions": [
          {
            "function": "concatString",
            "prefix": "(?i)cn=.*?,(.*?)",
            "suffix": ",%ldap.group.path%"
          }
        ],
        "targetVariable": "nestedPathRegex"
      },
// If a group is not a direct member of the configured group base
path, then function getMatchedRegexGroup extracts the nested path from the
distinguishedName of this group,
// and maps the nested path to attribute
['urn:sap:cloud:scim:schemas:extension:ad:2.0:Group']['nestedPath']
      {
        "condition": "('%ldap.attribute.group.id%' ==
'%ldap.attribute.dn%')",
```

```
        "sourcePath": "$.%ldap.attribute.group.id%[0]",
        "functions": [
          {
            "function": "getMatchedRegexGroup",
            "regex": "${nestedPathRegex}",
            "groupIndex": 1
          }
        ],
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:Group']['nestedPath']",
        "defaultValue": ""
      },
      {
        "sourcePath": "$.sAMAccountName[0]",
        "targetPath": "$.displayName"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.member",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members[?(@.value)]",
        "optional": true
      }
    ]
  }
}
```

As result of this mapping, that is how the data from Microsoft Active Directory looks like before and after the read transformation:

Source JSON Data (as read from Microsoft Active Directory)	Intermediate JSON Data (as a result from the transformation)

Sample Code
`...`
`"memberOf": [`
`"SALES_US",`
`"SALES_EU"`
`]`
`…`
	Sample Code
	`...`
	`"groups":[`
	`{`
	`"value": "SALES_US"`
	`},`
	`{`
	`"value": "SALES_EU"`
	`},`
	`]`
	`…`

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.50 Microsoft Entra ID

Follow this procedure to set up Microsoft Entra ID (formerly known as Microsoft Azure Active Directory) as a source system.

Prerequisites

- You've logged on to Microsoft Azure Portal, with credentials for a user with directory role **Global administrator**. For more information, see Microsoft Entra built-in roles .
- In *Azure Active Directory* > *App registrations*, you've registered an application with a secret key and permissions for Microsoft Graph API. These permissions must be consented by an administrator. For more information, see Microsoft Graph permissions reference .
- (Relevant to target systems) Your registered application is assigned the **User Account Administrator** role. This role allows you to deprovision users. For more information, see Add-MsolRoleMember .

> **Note**
>
> If this role isn't assigned, you can only disable users. To do that, set the `accountEnabled` property to **false**. For more information, see MS Graph: user resource type

Permissions

Assign the following permissions to your application, according to your scenario. Also, the permissions have to be of type *Application*.

- Users – *User.Read.All*
- Groups – *Group.Read.All*

For more information, see MS Graph: Users and MS Graph: Groups

Context

When using it as a source system, you can read both users and groups from Azure AD and provision them to any target system you've added in the Identity Provisioning user interface (if it supports groups).

If you've successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Microsoft Entra ID* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **https://graph.microsoft.com**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the application ID registered in your Azure AD subscription (see the **Prerequisites** section).
`Password`	(Credential) Enter the secret key associated to your app registration.
`aad.domain.name`	Enter one of the verified domain names from the corresponding Azure AD tenant. On this domain, you perform the provisioning operations. For more information, see Managing custom domain names in your Microsoft Entra ID.
`OAuth2TokenServiceURL`	Enter: **https://login.microsoftonline.com/<your_domain>/oauth2/token**, where `<your_domain>` is the domain name you have set in the **`aad.domain.name`** property.
(Optional) `aad.oauth2.resource.name`	Specifies the OAuth2 resource name for Microsoft Graph API. Enter: **https://graph.microsoft.com** You can change the Microsoft Graph endpoint to match your organization's cloud environment. For more information, see Microsoft Graph national cloud deployments.

Property Name	Description & Value
(Optional) `aad.group.member.attributes`	This property defines the attributes of a group member to be read by the Identity Provisioning. By default, it always reads the **type** and the **id** of a member. If you want the Identity Provisioning to read additional attributes, enter them as a single or a comma-separated value. For example: **Example** • If you want to read the e-mails too, enter: `aad.group.member.attributes=`*mail* This reads a member's type, ID, and e-mail. • If you want to read multiple additional attributes, enter: `aad.group.member.attributes=`*mail,mobilePhone,displayName* This reads a member's type, ID, e-mail, phone, and display name.
(Optional) `aad.user.attributes.membership.active`	Use this property if you want to retrieve information about all the groups to which the users are assigned (if any). • If the property is missing, or is set to *false* – group membership details for the users will not be extracted. • If the property is set to *true* – group membership details for the users will be extracted. To learn more, see: List of Properties [page 80]
(Optional) `aad.user.filter`	Use this property to filter users by specific criteria, according to the Microsoft Graph REST API . **Note** This property replaces the deprecated `msgraph-filter` property. To learn more, see: List of Properties [page 80]
(Optional) `aad.group.filter`	Use this property to filter groups by specific criteria, according to the Microsoft Graph REST API .

Property Name	Description & Value
(Optional) `aad.user.filter.group.filter.combine`	Use this property to filter users based on their group assignments. When set to **true**, this property combines user and group filters defined on the `aad.user.filter` and `aad.group.filter` properties to further narrow the search results. This way, only users that meet the following filtering criteria are returned: • Users that match the user filter and at the same time are members of groups that match the group filter. • Members of the filtered groups that match the user filter. When set to **false**, user and group filters are not combined. To learn more, see: List of Properties [page 80] Identity Provisioning: How to Get Users Based on Group Assignments from MS Azure AD
(Optional) `aad.user.attributes`	Defines which user attributes are read from Microsoft Entra ID system. The property is set during system creation with the following default value: *id,mail,userPrincipalName,displayName,mailNickname,givenName,surname,mobilePhone,businessPhones* This means that by default, Identity Provisioning will read from Microsoft Entra ID the user attributes defined in the property value. Those attributes are used in the default read transformation. To check the complete set of user attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: User Properties To learn more, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `aad.group.attributes`	Defines which group attributes are read from Microsoft Entra ID system. The property is set during system creation with the following default value: *id,displayName,mailNickname* This means that by default, Identity Provisioning will read from Microsoft Entra ID the group attributes defined in the property value and will also return the *members* attribute. Those attributes are used in the default read transformation. To check the complete set of group attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: Group Properties To learn more, see: List of Properties [page 80]
(Optional) `aad.entities.top`	This property defines the number of entities to be read per page. Default value: *100*
(Deprecated) `oauth.resource.name`	Enter: **https://graph.microsoft.com** **Note** The **oauth.resource.name** property has been deprecated, as it is no longer needed by the MS Entra ID connector. Use the **aad.oauth2.resource.name** property instead.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Entra ID* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in your Microsoft Entra ID. For more information, see:

   Manage Transformations [page 2439]

   MS Graph: Users

   MS Graph: Groups

   Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "$.userPrincipalName EMPTY false",
    "mappings": [
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.mailNickname",
        "optional": true,
        "targetPath": "$.externalId",
        "correlationAttribute": true
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.mail",
        "targetPath": "$.emails[0].value",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.userPrincipalName",
        "targetPath": "$.userName",
        "correlationAttribute": true
      },
      {
        "sourcePath": "$.displayName",
        "optional": true,
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.surname",
        "optional": true,
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.mobilePhone",
        "optional": true,
        "targetPath": "$.phoneNumbers[0].value"
      },
      {
        "condition": "$.mobilePhone EMPTY false",
        "constant": "mobile",
        "targetPath": "$.phoneNumbers[0].type"
      },
      {
        "sourcePath": "$.businessPhones[0]",
        "optional": true,
        "targetPath": "$.phoneNumbers[1].value"
      },
      {
        "condition": "$.businessPhones.length() > 0",
        "constant": "work",
        "targetPath": "$.phoneNumbers[1].type"
      },
```

```
      {
        "sourcePath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups"
      },
      {
        "sourcePath": "$.manager.id",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
        "optional": true
      },
      {
        "sourcePath": "$.manager.displayName",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['displayName']",
        "optional": true
      }
    ]
  },
  "group": {
    "ignore": true,
    "mappings": [
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.id",
        "targetVariable": "entityIdSourceSystem"
      },
      {
        "sourcePath": "$.mailNickname",
        "optional": true,
        "targetPath": "$.externalId"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members"
      },
      {
        "targetPath": "$.members[*].id",
        "constant": "value",
        "type": "rename",
        "optional": true
      },
      {
        "condition": "'%ips.application.id%' !== 'null'",
        "constant": "%ips.application.id%",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
      },
      {
```

```
        "constant": "userGroup",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {
        "constant": "readWrite",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      }
    ]
  }
}
```

Custom Configurations

Goal	Action	Result
You want Identity Provisioning to read the additional user attributes specified in property `aad.user.attributes` and write them successfully in the target system.	Extend the "*user*" mapping as follows: `{ "user": { "condition": "$.userPrincipalName EMPTY false", "mappings": [ { "sourcePath": "$", "targetPath": "$" }, { "sourcePath": "$.id", "targetVariable": "entityIdSourceSystem" }, ...`	For example, you specify the `aad.user.attributes` property and set its value to: *id,mail,userPrincipalName,city,department,companyName* As a result, every user in the target system will have the following attributes populated – ID, e-mail, user principle name, city, department, and company name. Returned information of an exemplary user: `... { "Resources":[ { "id":"555-aaaa-333-abcd-111222333", "mail":"john.smith@domain.com", "userPrincipalName":"abc@something.onmicrosoft.com", "city": "Sofia", "department":"029", "companyName":"SAP" } ... ] }`

Goal	Action	Result
You want Identity Provisioning to read the additional group attributes specified in property `aad.group.attributes` and write them successfully in the target system.	Extend the "*group*" mapping as follows: `{ "group": { "ignore": false, "mappings": [ { "sourcePath": "$", "targetPath": "$" }, { "constant": "urn:ietf:params:scim:schemas:core:2.0:Group", "targetPath": "$.schemas[0]" }, ...`	Example: Specify the `aad.group.attributes` property and set its value to: *id,displayName,recommendation,isSubscribedByMail* As a result, every group in the target system will have the following attributes populated – ID, display name, date and time of the last renewal, and information if it's subscribed by e-mail or not. Returned information of an exemplary group: `... { "Resources":[ { "id":"12345-ccc-000-xyz-777888999", "displayName":"ImportantGroup3", "renewedDateTime":"2018-01-01T00:00:00Z", "isSubscribedByMail":"true" } ... ] }`

Goal	Action	Result

You want the returned value of a group member to be not the ID but a different attribute.	In the `"group"` mapping, replace **id** with the new attribute. For example:
	
	If you replace *id* with *mail*, the transformation will look like this:
	
	`...`
	`{`
	`"sourcePath": "$.members",`
	`"preserveArrayWithSingleElement": true,`
	`"optional": true,`
	`"targetPath": "$.members"`
	`},`
	`{`
	`"targetPath": "$.members[*].mail",`
	`"constant": "value",`
	`"type": "rename",`
	`"optional": true`
	`}`
	`...`
	
	⚠ Caution
	Make sure that you've added this attribute as a value of property *aad.group.member.attributes*.
		Returned information of an exemplary group member:
		
		`...`
		`{`
		`"members":[`
		`{`
		`"id":"5555555-aaaa-333-abcd-1111122223333",`
		`"type":"user",`
		`"value":"johnsmith@mail.acme.com"`
		`}`
		`]`
		`}`
		`...`

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.51 Procurement Data Warehouse

Follow this procedure to set up Procurement Data Warehouse as a source system.

Prerequisites

- You obtain credentials to access the Procurement Data Warehouse API.

  > **Note**
  >
  > To obtain credentials to access the Procurement Data Warehouse API, create a case to the component *BNS-ARI-PRI*.
  >
  > In response to the case, SAP provides the certificate needed to access the API as well as the URL for the procurement data warehouse enrollment service, which is landscape-specific and starts with `*.cloud.sap`.

- You established trust between your SAP BTP subaccount and the SAP Cloud Identity Services - Identity Authentication service. For more information, see Establishing Trust Automatically.
- To configure your *Procurement Data Warehouse* provisioning system (see the procedure below), you will need to map your SAP Ariba application parameters to the relevant Identity Provisioning properties. The property mapping between the two systems is as follows:

Procurement Data Warehouse Application	Identity Provisioning	Values
API URL	URL	Examples: • US: **https://openapi.ariba.com** • Europe: **https://eu.openapi.ariba.com**
procurement data warehouseOAuth Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token**
OAuth Client ID	`client_id`	Enter the OAuth Client id used for access token retrieval.

- To load transaction data into procurement data warehouse, you must have one or more of the following SAP Ariba applications:
  - SAP Ariba Buying
  - SAP Ariba Buying and Invoicing
  - Guided sourcing capability for SAP Ariba Sourcing
  - SAP Ariba Contracts
  - SAP Ariba Spend Analysis

Context

The Procurement Data Warehouse is a capability that feeds analytics information from SAP Ariba applications, including guided sourcing capability for SAP Ariba Sourcing, SAP Ariba Buying and Invoicing, and SAP Spend Control Tower, to the embedded SAP Analytics Cloud. It provides data transfer, storage, loading, and reporting, and it drives visualization through advanced analytics dashboards.

You can use Identity Provisioning to configure procurement data warehouse as a source system where you can read users and groups and provision them to target systems of your choice for custom reporting. The source system consumes SCIM 2.0 API provided by procurement data warehouse.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *Procurement Data Warehouse* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP Analytics Cloud URL for your procurement data warehouse.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`client_id`	Enter the OAuth client id, generated for your procurement data warehouse. (see the **Prerequisites** section)
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your procurement data warehouse instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page.
(Optional) `pdw.user.filter`	When specified, only those procurement data warehouse users matching the filter expression will be read. For example: • *userName eq "Julie Armstrong"* • *userName sw "J"* • *emails eq "julie.armstrong@example.com"*

Property Name	Description & Value
(Optional)`pdw.group.prefix`	This property distinguishes procurement data warehouse groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`PDW_`** You can use the example value or provide your own. When **set in the source system**, the prefix will be pre-pended to the name of the groups that are read from the procurement data warehouse source system and will be provisioned to the target system with the following name pattern: **`PDW_<GroupDisplayName>`**. This way procurement data warehouse groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the procurement data warehouse groups will be read and provisioned to the target system with their actual display names.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Procurement Data Warehouse* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Procurement Data Warehouse system. For more information, see: Manage Transformations [page 2439]

   > ### Note
   >

                    {
                        "condition": "'%pdw.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "applyOnElements": true,
                        "applyOnAttribute": "display",
                        "prefix": "%pdw.group.prefix%"
                    }
                ]
            }
        ]
    },
    "group": {
        "ignore": true,
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "targetPath": "$.schemas",
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "'%pdw.group.prefix%' !== 'null'",
                        "function": "concatString",
                        "prefix": "%pdw.group.prefix%"
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']"
            },
            {
                "sourcePath": "$.members",
                "targetPath": "$.members",
                "optional": true,
                "preserveArrayWithSingleElement": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:group-custom-
parameters:1.0']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:group-custom-
parameters:1.0']",
                "optional": true
             },
            {
                "condition": "'%ips.application.id%' !== 'null'",
                "constant": "%ips.application.id%",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']"
```

```
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
                "optional": true
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

Configure OAuth Certificate Authentication [page 2456]

1.6.1.52 SCIM System

Follow this procedure to set up a SCIM system as a source system.

Prerequisites

- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only if the SCIM system is exposed in a private corporate network. For more information, see Cloud Connector.

- You have technical user credentials for a SCIM system, with read/write access permissions, depending on the scenario you want to implement. In case OAuth is used for authentication, client ID and secret are required when creating a destination for access token retrieval.

Context

Create a general SCIM 2.0 based source system to read users and groups from it.

Procedure

1. (Optional) If the SCIM system is exposed in a private corporate network, add an access control system mapping in Cloud Connector. For more information, see Configure Access Control (HTTP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
3. Add *SCIM* as a source system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the service URL. For example: **`http://<cloudfoundry_server>.com/api/uaa/`**
`ProxyType`	Depending on your network exposure, enter one of the following: • *Internet* • *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	You can specify one of the following: • Technical user ID • Client ID for OAuth HTTP destinations. It's used for retrieving of the access token.
`Password`	(Credential) You can enter one of the following: • Technical user password • Client secret for OAuth HTTP destinations. It's used for retrieving of the access token.

Property Name	Value
`OAuth2TokenServiceURL`	If you need to make OAuth authentication to the system, enter the URL to the access token provider service for OAuth HTTP destinations. For example: **`https://<token_provider>.com/api/oauth2/v2.0/token`**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SCIM* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see Manage Transformations [page 2439].

   - **Mapping logic** – the behavior of the default transformation logic is to read all user attributes from the source SCIM system, and then map them to the internal SCIM representation. It uses `entityIdSourceSystem` to store the unique ID of the identity. The ID is removed by default, because it is specific for the source system.
   - **User off-boarding** – it depends on the target system API. When a user is deleted from the SCIM system, the deletion status is considered and depends on the user status handling of the target system. The user will be either deleted or set as **inactive**.

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "sourcePath": "$.userName",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.emails[?(@.primary== true)].value",
                "optional": true,
                "correlationAttribute": true
            },
            {
                "type": "remove",
                "targetPath": "$.id"
```

```
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            }
        ]
    },
    "group": {
        "ignore": true,
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            },
            {
                "type": "remove",
                "targetPath": "$.id"
            },
            {
                "type": "remove",
                "targetPath": "$.meta"
            }
        ]
    }
}
```

6. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.1.53 SSH Server (Beta)

Follow this procedure to set up an SSH server (Beta) as a source system.

Prerequisites

- You have credentials for a tenant in SAP Business Technology Platform. For more information, see: Accounts
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only when your SSH server resides in a remote system, outside your Neo environment. For more information, see Cloud Connector.

> ### Note
>
> This is a beta feature available on SAP Business Technology Platform. For more information, see: *Enable beta features* in Change Subaccount Details

Context

SSH Server is a system (connector) in beta state. It helps you execute bash scripts through SSH connection. The configuration allows you to attach separate scripts per entity lifecycle callback (such as user create, group create/update, and so on). This system helps you connect to remote machines via SSH tunnel, with or without use of the Cloud Connector, depending on whether the SSH port is visible or not.

The bash scripts can take as parameters fields that are coming from the entity JSON data. For example: *sudo su - vcap /home/myscript.sh $.userName $.email*

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Add *SSH Server (Beta)* as a source system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Below are listed all available SSH Server properties. Some of them can be mandatory and others – optional, depending on your scenario.

   Mandatory Properties

Property Name	Description & Value
`ProxyType`	Possible values: • **Internet** – if the SSH port is visible in your Neo environment • **OnPremise** – if the SSH port is not directly accessible, and you have to use theCloud Connector. You have to configure TCP protocol connection to the SSH host and port (specify the configuration properties `ssh.host` and `ssh.port`).
`CloudConnectorLocationId`	Relevant when the proxy type is *OnPremise*. Use it only if your SAP Business Technology Platform account uses more than one Cloud Connector.

Property Name	Description & Value
`ssh.auth.type`	Supported SSH authentication types: • **key** • **pwd** • **otp** • **key+otp** • **key+pwd** • **pwd+otp** • **key+pwd+otp**
`ssh.host`	
`ssh.port`	22
`ssh.username`	
`ssh.password`	(Credential) Taken into account only if the authentication type includes **pwd**. That means any of the following: • `ssh.auth.type` = *pwd* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+pwd+otp*
`ssh.totp.secret.key`	(Credential) Taken into account only if the authentication type includes **otp**. That means any of the following: • `ssh.auth.type` = *otp* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd+otp*
`ssh.private.key.type`	The type of the SSH private key. Possible values: • **ssh-rsa** • **ssh-dsa** Default value: *ssh-rsa* **Note** If you choose *ssh-rsa*, the key should be in format **PKCS #8**, non-encrypted.
`ssh.private.key`	(Credential) Taken into account only if the authentication type includes **key**. That means any of the following: • `ssh.auth.type` = *key* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *key+pwd+otp*

Property Name	Description & Value
`ssh.read.groups.command`	Path to the bash command you need to execute to read groups.
`ssh.read.users.command`	Path to the bash command you need to execute to read users.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SSH Server (Beta)* source system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SSH server. For more information, see Manage Transformations [page 2439].

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem",
                "correlationAttribute": true
            },
            {
                "sourcePath": "$.userName",
                "optional": true,
                "correlationAttribute": true
            }
        ]
    },
    "group": {
        "ignore": true,
        "mappings": [
            {
                "targetPath": "$",
                "sourcePath": "$"
            },
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdSourceSystem"
            }
        ]
    }
}
```

5. Now, add a target system to provision users and groups into it. Choose from: Target Systems [page 936]

Next Steps

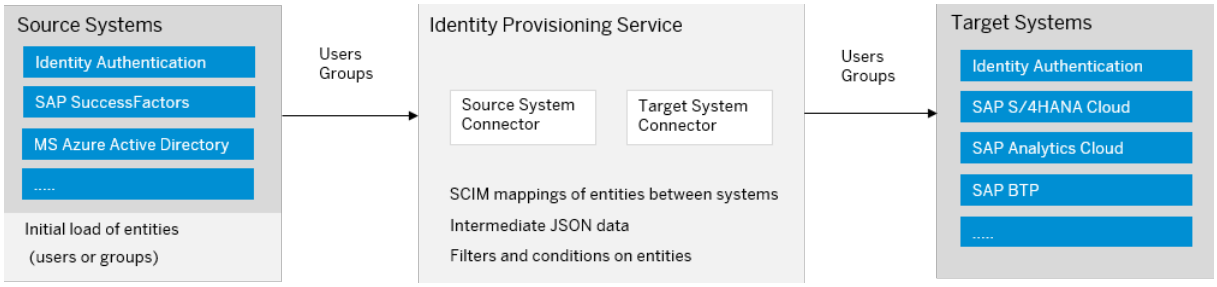
- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2 Target Systems

A target system is the connector used for writing entities.

Target systems are usually cloud systems, where Identity Provisioning creates or updates the entities read from the source system.

A target system can be connected to a single or multiple source systems. In the case of multiple source systems, we recommend that you run the provisioning jobs **successively** for each system, not simultaneously. This way, you'll avoid incorrect overwriting or merging of entity data, hence failed provisioning jobs.



> ⚠ Restriction
>
> By default, the maximum number of productive target systems you are allowed to add for your tenant is **50**. This restriction is valid for *Customer Managed* systems only.
>
> If your business requires using more systems, create an incident for component *BC-IAM-IPS* to request them. Describe your scenarios and provide a reason why you need the additional systems.

System Types [page 70]

1.6.2.1 Identity Authentication

Follow this procedure to set up SAP Cloud Identity Service – Identity Authentication as a target system.

Prerequisites

To establish the connection between Identity Provisioning and Identity Authentication, you need to set up the technical user (of type *System*) in Identity Authentication and assign this user the necessary authorizations. You have the option to do it either now, as a prerequisite, or while configuring Identity Authentication as a target system, as described in step 3.

Context

Identity Authentication provides authentication and single sign-on for users in the cloud.

Using Identity Provisioning, you can read corporate users from on-premise or cloud systems, and provision them to the Identity Authentication user store. This way, you can implement secure authentication, single sign-on (SSO), strong authentication and mobile SSO so that the provisioned users have access to the business applications of your company. For example, you can implement two-factor authentication and mobile SSO for SAP SuccessFactors users.

You can use the Identity Provisioning UI to configure Identity Authentication as a target system where you can provision users, groups and group members. The target system consumes SCIM 2.0 API provided by Identity Authentication.

There are two versions of the Identity Authentication SCIM API. They are controlled by the `ias.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on July 9, 2021) - Identity Authentication SCIM API (in short, SCIM API version 1) is used.

  > ### Note
  >
  > The SAP Cloud Identity Services – Identity Authentication SCIM API (version 1) will be decommissioned on November 30, 2028. You must use its successor, the Identity Directory SCIM API. This requires updating your Identity Authentication connector from version 1 to version 2, as described in Update Connector Version [page 2424].

- When the value is set to **2** - Identity Directory SCIM API (in short, SCIM API version 2) is used. This value is set automatically for all manually created systems in the Identity Provisioning UI after versioning was introduced on July 9, 2021.
  SCIM API version 2 does not support managing of group assignments via the SCIM user resource. The "groups" attribute of the user is read-only. This means that the user group assignments should be managed via the SCIM group resources using the "members" attribute (as it is defined by the SCIM standard). Also, the group resource mapping in the transformation is not ignored by default, as it is in SCIM API version 1.

> **Note**
>
> Identity Authentication (using SCIM API version 2) and Identity Directory are sometimes used interchangeably. Identity Directory is the persistency layer of SAP Cloud Identity Services – Identity Authentication.

To create Identity Authentication as a target system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Identity Authentication* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and Identity Authentication and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added Identity Authentication target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Manage Certificates [page 2450].

      Skip step **a.** if you want to use basic authentication.

      In SAP Cloud Identity Services administration console, perform the next steps. They are relevant for both basic and certificate-based authentication.

   b. Add System as administrator and provide the respective credentials.

      For basic authentication, provide a password. The user ID will be generated automatically when you set the password for the first time.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Save your changes.

   d. Make sure *Manage Users* and *Manage Groups* authorization roles are enabled for the technical user. This way, you can create, edit and delete users and groups in the Identity Authentication user store.

4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
URL	Specify the URL of the Identity Authentication tenant of your company. For example: **https://mytenant.accounts.ondemand.com** **Note** If your Identity Authentication Shanghai (China) tenants reside on SAP BTP, Neo, you should use the following URL pattern: *https://<tenant_ID>.accounts.sapcloud.cn/*
ProxyType	Enter: *Internet* The Identity Authentication is a cloud solution and is outside of your company on-premise infrastructure.
Authentication	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
User	Valid if *BasicAuthentication* is configured as authentication method. Enter the Client ID (previously User ID) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*. For example: *1ab7c243-5de5-4530-8g14-1234h26373ab* If your technical user was created before *January 2020*, enter the T-user. For example: *T000003*
Password	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the Client Secret (previously Password) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*.

Optional Properties

Property Name	Description & Value
• `ias.<property_name>` • `scim.<property_name>`	When using SCIM API version 2, property names start with `ias` prefix, for example: `ias.user.unique.attribute`. When using SCIM API version 1, property names start with `scim` prefix, for example: `scim.user.unique.attribute`. For more information, see List of Properties [page 80]. Use the main search or filter properties by *Name* or *System Type* columns.
`ias.user.unique.attribute`	This property defines by which unique attribute(s) an existing user will be resolved in the event of conflicting users. It appears by default when the system is created, and its value is set to *userName*. Other possible values: • *emails[0].value* • *userName,emails[0].value* • *phoneNumbers[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes If the service finds a user on the target system through this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system through this filter, the creation will fail. For more information, see: List of Properties [page 80]
`ips.failed.request.retry.attempts`	Predefined value: *2*
`ips.failed.request.retry.attempts.interval`	Predefined value: *60*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

5. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Identity Authentication* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

When Identity Authentication is configured as a target system, the default transformation logic writes all the user attributes in the Identity Authentication user store. The logic is provided by the Identity Authentication SCIM REST API, which then maps the attributes to the internal SCIM representation.

Handling Application-Specific Groups

In case you want to provision application-specific groups between the following pairs of provisioning systems:

Source System	Target System
Identity Authentication (SCIM API version 2)	Identity Authentication (SCIM API version 2)
Identity Authentication (SCIM API version 2)	Local Identity Directory
Local Identity Directory	Identity Authentication (SCIM API version 2)

The Identity Provisioning will search and try to resolve the groups by the attribute values of `displayName`, `applicationId`, and `type`. To ensure successful provisioning, you must define value mappings for the attribute `applicationId` in the transformation mappings of the source or the target system. You should define to which `applicationId` in the target system will be mapped the `applicationId` read from the source system.

For example:

```
{
"sourcePaths": [
    "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']"
],
"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']",
"valueMappings": [
    {
        "key": [
            "<your_source_system_applicationId>"
        ],
        "mappedValue": "<your_target_system_applicationId>"
    }
    ],
    "condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
    "type": "valueMapping",
    "defaultValue": ""
}
```

For more information, see Transformation Expressions [page 391] → section **valueMapping**.

SCIM API version 1: Identity Authentication: SCIM REST API

SCIM API version 2: Identity Directory SCIM API

When Identity Authentication is configured as a target system, the default transformation logic:

- Reads all user attributes from the intermediate SCIM representation.
- Skips some of the attributes from the identity records.

This way, the transformation logic ensures that the identity data, sent to the Identity Provisioning SCIM REST API, is consistent.

Default transformation for SCIM API version 1:

Code Syntax

```
{
  "user": {
    "condition": "($.emails.length() > 0) && ($.name.familyName EMPTY
false) && isValidEmail($.emails[0].value)",
    "mappings": [
      {
        "sourcePath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.corporateGroups"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
        "targetPath": "$.schemas[0]"
      },
      {
        "constant":
"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
        "targetPath": "$.schemas[1]"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "optional": true
      },
      {
        "sourcePath": "$.emails[*].value",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.emails[?(@.value)]"
      },
      {
        "sourcePath": "$.userType",
        "targetPath": "$.userType",
        "defaultValue": "employee",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
```

```
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificPrefix",
        "targetPath": "$.name.honorificPrefix",
        "optional": true
      },
      {
        "sourcePath": "$.addresses",
        "targetPath": "$.addresses",
        "preserveArrayWithSingleElement": true,
        "defaultValue": [],
        "optional": true,
        "functions": [
          {
            "function": "putIfAbsent",
            "key": "type",
            "defaultValue": "work"
          },
          {
            "condition": "(@.type NIN ['work', 'home'])",
            "function": "putIfPresent",
            "key": "type",
            "defaultValue": "work"
          }
        ]
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$.phoneNumbers",

            "replacement": "_"
          }
        ]
      },
      {
        "scope": "createEntity",
        "optional": true,
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']"
      },
      {
        "optional": true,
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['description']",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['description']"
      },
      {
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "sourcePath": "$.members[*].value",
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "type": "resolveEntityIds"
          }
```

```
        ]
      }
    ]
  }
}
```

Default transformation for SCIM API version 2:

Code Syntax

```
{
  "user": {
    "condition": "($.emails EMPTY false) && ($.userName EMPTY false) &&
isValidEmail($.emails[0].value)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant":
["urn:ietf:params:scim:schemas:core:2.0:User","urn:ietf:params:scim:schemas
:extension:enterprise:2.0:User","urn:ietf:params:scim:schemas:extension:sap
:2.0:User","urn:sap:cloud:scim:schemas:extension:custom:2.0:User"],
        "targetPath": "$.schemas"
      },
      {

['externalLocation']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalLocation']",
        "scope": "createEntity"
      }
    ]
  }
}
```

→ Remember

If you set `$.userType` to "**public**", all passwords will be written by default in the Identity Authentication. Thus, all provisioned users will successfully sign in to Identity Authentication target system.

When `$.userType` is set to "**employee**", the sign-in behavior of the provisioned users depends on whether users have been created with or without a password, and where these passwords are stored. Thus, you need to modify the target transformations accordingly in order for the users to successfully sign in to the Identity Authentication console.

To learn more, see *Guided Answers*: Identity Authentication: Provisioned Users Can't Sign In

6. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ⚠ Caution
>
> By default, the **email** attribute is unique for *Identity Authentication* but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in *Identity Authentication*.
>
> To learn more about how to fix this issue or prevent it from happening, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from Identity Authentication target, see: Exclude Users from Provisioning to Target Systems

If you have configured the **email** attribute to NOT be unique in *Identity Authentication*, then ignore this **Caution** note and the guided answer. For more information about configurable attributes, see: Identity Authentication: Configure User Identifier Attributes

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.2 Intelligent Opportunity Analyzer

Follow this procedure to set up intelligent opportunity analyzer as a target system.

Prerequisites

You have created an instance and generated a service key for the *scim* service plan of *Intelligent Opportunity Analyzer*. For more information, see Assigning the Entitlements for Intelligent Opportunity Analyzer to Your Subaccounts.

Context

Intelligent opportunity analyzer is a service that comes integrated with SAP Ariba Category Management for identifying and managing opportunities that lead to improving the performance of a purchasing category.

You can use Identity Provisioning to configure intelligent opportunity analyzer as a target system where you can provision users from source systems.

> **Note**
>
> Intelligent opportunity analyzer does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Intelligent Opportunity Analyzer* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*

Property Name	Value
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key. Ensure to append the value `/oauth/token?grant_type=client_credentials`.
(Optional) `ioa.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. Possible values: *userName* and *emails[*].value* For more information, see: **User Update and Uniqueness** section below and List of Properties [page 80].
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Intelligent Opportunity Analyzer* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your intelligent opportunity analyzer system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target intelligent opportunity analyzer entity.

   > ### Note
   >
   > The documentation for the Intelligent Opportunity Analyzer API and its integration with Identity Provisioning is still under development. Refer to the Intelligent Opportunity Analyzer Setup for updates.

User Update and Uniqueness

The write transformation of intelligent opportunity analyzer supports two user unique attributes for managing conflict resolution: *username* and *email*. Both of the attributes are mandatory. The email is a multivalue attribute, indicating that a user may have multiple unique emails.

The uniqueness of a user in the target system is determined not only by the individual attributes or the combination of both, but also by considering whether one or multiple existing users in the target system share the same values for these unique attributes. Have in mind the following specifics when updating an existing user in the target system, in accordance with the configuration of the `ioa.user.unique.attribute` property:

- When `ioa.user.unique.attribute`= *userName*
  If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same email, but a different userName, the user provisioning will fail. In this case, Identity Provisioning will try to create a new user but will fail, since a user with the same email already exists.
- When `ioa.user.unique.attribute`= *emails[*].value*
  If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same username, but a different email, the user provisioning will fail. In this case, Identity Provisioning will try to create a new user but will fail, since a user with the same username already exists.
- When `ioa.user.unique.attribute`= *userName, emails[*].value*
  - If a user in the source system, with a specific username and multiple emails, matches an existing user in the target system by the same username and at least one identical email, the user in the target system will be updated.
  - If a user in the source system, with a specific username and multiple emails, matches multiple existing users in the target system (each sharing one of the multiple emails but having different usernames), the user provisioning will fail. In this case, the user will neither be created nor updated.

Default transformation:

Code Syntax

```
{
  "user":{
    "mappings":[
     {
       "constant": [
         "urn:ietf:params:scim:schemas:core:2.0:User"
       ],
       "targetPath": "$.schemas"
     },
     {
       "sourceVariable": "entityIdTargetSystem",
       "targetPath": "$.id"
     },
     {
       "sourcePath": "$.userName",
       "targetPath": "$.userName"
     },
     {
       "sourcePath": "$.emails",
       "targetPath": "$.emails",
       "preserveArrayWithSingleElement": true
     },
```

```
        {
          "sourcePath":"$.loginName",
          "targetPath":"$.loginName",
          "optional":true
        },
        {
          "sourcePath":"$.name.givenName",
          "targetPath":"$.name.givenName",
          "optional":true
        },
        {
          "sourcePath":"$.name.familyName",
          "targetPath":"$.name.familyName",
          "optional":true
        },
        {
          "sourcePath":"$.name.formatted",
          "targetPath":"$.name.formatted",
          "optional":true
        },
        {
          "sourcePath":"$.name.middleName",
          "targetPath":"$.name.middleName",
          "optional":true
        },
        {
          "sourcePath":"$.name.honorificPrefix",
          "targetPath":"$.name.honorificPrefix",
          "optional":true
        },
        {
          "sourcePath":"$.name.honorificSuffix",
          "targetPath":"$.name.honorificSuffix",
          "optional":true
        },
        {
          "sourcePath":"$.active",
          "targetPath":"$.active"
        },
        {
          "sourcePath":"$.displayName",
          "targetPath":"$.displayName",
          "optional":true
        },
        {
          "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
          "optional": true,
          "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
        }
      ]
    }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.3 Local Identity Directory

Follow this procedure to set up Local Identity Directory as a target system.

Prerequisites

> **Note**
>
> The *Local Identity Directory* connector is available for both bundle and standalone tenants running on SAP Cloud Identity Services infrastructure.

Context

Identity directory is the user store of SAP Cloud Identity Services. It provides a central place for storing and managing users, groups and custom schemas through the System for Cross-domain Identity Management 2.0 REST API, in short Identity Directory SCIM API.

You can provision users and groups to the identity directory from various source systems by configuring the Local Identity Directory connector as a target system in the SAP Cloud Identity Services administration console. The entities are written to the identity directory of your current SAP Cloud Identity Services tenant. Therefore, you don't have to set up connectivity and authentication properties for the target system. In case you want to write entities to the identity directory in another tenant, add Identity Authentication (version 2) as a target system and configure the respective connectivity and authentication properties.

To create Local Identity Directory as a target system, proceed as follows:

Procedure

1. Sign in to SAP Cloud Identity Services administration console and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Local Identity Directory* as a target system.

   For more information, see Add New Systems [page 2415].
3. **Optional:** If needed, choose the *Properties* tab to configure patch and bulk operations.

Optional Properties

Property Name	Value
`idds.bulk.operations.max.count`	This property sets the number of operations to be performed in one bulk request. • Default value: *20* • Maximum value: *100*
`idds.support.bulk.operation`	This property enables bulk operations for users and groups. • When bulk operations are enabled, Identity Provisioning creates, updates, and deletes multiple users and groups in one request. • When bulk operations are not enabled, Identity Provisioning creates, updates, and deletes one user at a time.
`idds.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with **PATCH** requests, and below which they are provisioned with **PUT** request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. • Default value: *20 000* • Minimum value: *1* • Maximum value: *200 000* **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members.

Local Identity Directory properties are prefixed with `idds.<property_name>`. For more information, see List of Properties [page 80].

4. **Optional:** Configure transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the Local Identity Directory target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   When Local Identity Directory is configured as a target system, the default transformation logic writes the user attributes in the user store of SAP Cloud Identity Services. The logic is provided by the Identity Directory SCIM API, which then maps the attributes to the internal SCIM representation.

   ### Handling Application-Specific Groups

In case you want to provision application-specific groups between the following pairs of provisioning systems:

Source System	Target System
Identity Authentication (SCIM API version 2)	Identity Authentication (SCIM API version 2)
Identity Authentication (SCIM API version 2)	Local Identity Directory
Local Identity Directory	Identity Authentication (SCIM API version 2)

The Identity Provisioning will search and try to resolve the groups by the attribute values of `displayName`, `applicationId`, and `type`. To ensure successful provisioning, you must define value mappings for the attribute `applicationId` in the transformation mappings of the source or the target system. You should define to which `applicationId` in the target system will be mapped the `applicationId` read from the source system.

For example:

```
{
"sourcePaths": [
    "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']"
],
"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']",
"valueMappings": [
    {
        "key": [
            "<your_source_system_applicationId>"
        ],
        "mappedValue": "<your_target_system_applicationId>"
    }
    ],
    "condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
    "type": "valueMapping",
    "defaultValue": ""
}
```

For more information, see Transformation Expressions [page 391] → section **valueMapping**.

You can change the default transformation mapping rules to reflect your current setup of entities in your Local Identity Directory. For more information, see:

- Manage Transformations [page 2439]
- SCIM API version 2: Identity Directory SCIM API

Default transformation for Local Identity Directory:

Code Syntax

```
{
    "user": {
        "condition": "($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value)",
        "mappings": [
            {
                "targetPath": "$.id",
```

```
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "targetPath": "$.schemas",
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:User",

"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:User",
                    "urn:sap:cloud:scim:schemas:extension:custom:2.0:User"
                ]
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['emails']",
                "preserveArrayWithSingleElement": true,
                "scope": "createEntity",
                "functions": [
                    {
                        "function": "putIfAbsent",

            }
        ]
    }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ⚠ Caution
>
> By default, the **email** attribute is unique for Local Identity Directory but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in Local Identity Directory.
>
> To learn more about how to fix this issue or prevent it from happening, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from Local Identity Directory target, see: Exclude Users from Provisioning to Target Systems

If you have configured the **email** attribute to NOT be unique in Local Identity Directory, then ignore this **Caution** note and the guided answer. For more information about configurable attributes, see: Configure User Identifier Attributes

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.4 SAP Advanced Financial Closing

Follow this procedure to set up SAP Advanced Financial Closing as a target system.

Prerequisites

You have created an instance and generated a service key for the standard service plan of SAP Advanced Financial Closing. For more information, see: How to Manage User Access Using the SCIM API Provided.

The service key contains the API URL and the OAuth credentials (`clientid` and `clientsecret`) under the `uaa` property.

Context

SAP Advanced Financial Closing allows you to define, automate, process, and monitor the financial closing tasks for the entities of your organization. It is an SAP BTP application that runs in an SAP BTP subaccount.

You can use Identity Provisioning to configure SAP Advanced Financial Closing as a target system for provisioning users and user groups from various source systems.

> **Note**
>
> The last active user in a user group cannot be deleted, as specified in the restriction described in How to Delete Users.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Advanced Financial Closing* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under *endpoints* > *scim2* without adding the path information. For example: `https://afc-production-afc-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user ID provided by the service key under *uaa* > *clientid*.
`Password`	(Credential) Enter the password provided by the service key under *uaa* > *clientsecret*.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL provided by the service key of your SAP Advanced Financial Closing instance. It follows the pattern: **`<uaa.url>/oauth/token`**, where: • `<uaa.url>` is the URL provided by the service key under *uaa* > *url*. • **`/oauth/token`** is the suffix you need to add.

Property Name	Value
`s4hana.afc.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. Possible values: • *userName* • *emails[0].value* • *userName,emails[0].value*
`s4hana.afc.group.unique.attribute`	If Identity Provisioning tries to provision a group that already exists in the target system (a conflicting group), this property defines the unique attributes by which the existing group will be searched and resolved. The default value is *displayName*.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map user and group attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Advanced Financial Closing* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Advanced Financial Closing system. For more information, see: Manage Transformations [page 2439].

   How to Manage User Access Using the SCIM API Provided

   SAP Business Accelerator Hub: SAP Advanced Financial Closing

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Advanced Financial Closing entity.

Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "('%s4hana.afc.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%s4hana.afc.group.prefix%.+/)] empty false)",
    "mappings": [
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",
          "urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
          "urn:ietf:params:scim:schemas:extension:sap:2.0:User"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath": "$.name.formatted",
        "targetPath": "$.name.formatted",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "condition": "$.emails[0].length() > 0",
        "targetPath": "$.emails[0].primary",
        "constant": true
```

```
      },
      {
        "sourcePath": "$.emails",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.emails",
        "functions": [
          {
            "function": "putIfAbsent",
            "key": "type",
            "defaultValue": "work"
          }
        ]
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.groups",
        "targetPath": "$.groups",
        "preserveArrayWithSingleElement": true,
        "optional": true
      }
    ]
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
s4hana.afc.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
s4hana.afc.group.prefix) && (isRegularGroup() ||
isApplicationSpecificGroup())",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:Group",
          "urn:sap:cloud:scim:schemas:extension:custom:2.0:Group"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
s4hana.afc.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%s4hana.afc.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
s4hana.afc.group.prefix)",
            "function": "replaceFirstString",
```

```
            "regex": "%s4hana.afc.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "optional": true,
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
s4hana.afc.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%s4hana.afc.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      }
    ]
  }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.5 SAP Advanced Workflow

Follow this procedure to set up a target connector for SAP Advanced Workflow.

Prerequisites

- You have technical credentials for SAP Advanced Workflow. Note that SAP Advanced Workflow is available to SAP SuccessFactors Incentive Management customers as an optional add-on. You create an Admin user in SAP SuccessFactors Incentive Management, which is synchronized with SAP Advanced Workflow. For more information, see: Adding an Admin User and Commissions User Synchronization.
- You have set up SSO between Identity Authentication and SAP Advanced Workflow. For more information, see Integration with SAP IdP.

Context

SAP Advanced Workflow enables you to analyse, organize, and execute business processes to connect people, data, and daily activities. Workflow provides you the tools you need to configure and customize your business processes based on your specific business needs.

After fulfilling the prerequisites, follow the procedure below to add a target system for SAP Advanced Workflow where you can provision **users** from source systems. This target system consumes Workflow SCIM API.

> ⓘ Note
>
> SAP Advanced Workflow does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Advanced Workflow* as a target system. For more information, see Add New Systems [page 2415].

3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Advanced Workflow system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP Advanced Workflow system.
`Password`	(Credential) Enter the password for your SAP Advanced Workflow user.
`awf.domain`	The domain name is the name of your SAP Advanced Workflow tenant. If you don't know your tenant name, contact your supervisor or administrator, or refer to the email notification you received when your account was created.
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Advanced Workflow* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Advanced Workflow. For more information, see:

Manage Transformations [page 2439]

The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. If the entity has more than one e-mail addresses, only one of them is used. It is either the e-mail set as primary in the source system, or if no primary e-mail is set, the one that comes first is used.

Default transformation:

Code Syntax

```
{
    "user": {
        "condition": "($.emails EMPTY true) ||
isValidEmail($.emails[0].value)",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": ["urn:ietf:params:scim:schemas:core:2.0:User",
"urn:ietf:params:scim:schemas:extension:sap.spm.workflow:2.0:User"],
                "targetPath": "$.schemas"
            },
                    {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true
            },
            {
                "sourcePath": "$.name.middleName",
                "targetPath": "$.name.middleName",
                "optional": true
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName",
                "optional": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.phoneNumbers",
                "targetPath": "$.phoneNumbers",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.timezone",
                "targetPath": "$.timezone",
                "optional": true
            }
        ]
    }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.6 SAP Analytics Cloud

Follow this procedure to set up SAP Analytics Cloud as a target system.

Prerequisites

- In SAP Analytics Cloud, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- Add an OAuth client with authorization grant **Client Credentials**. To learn how, see: Managing OAuth Clients and Trusted Identity Providers

Context

SAP Analytics Cloud is an all-in-one cloud product offered as software as a service for business intelligence, planning, and predictive analytics.

You can use Identity Provisioning to configure SAP Analytics Cloud as a target system where you can provision users and groups. The target system consumes SCIM 2.0 API provided by SAP Analytics Cloud. For more information, see SAP Analytics Cloud: User and Team Provisioning API.

There are two versions of the SAP Analytics Cloud SCIM API. They are handled by the `sac.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on April 10, 2023), SAP Analytics Cloud SCIM API version 1 is used. This is the default value.
- When the value is set to **2** - SAP Analytics Cloud SCIM API version 2 is used. This version is released with enhancements, such as: support for patch operations.

For more information on the differences between SAP Analytics Cloud SCIM API version 1 and 2, see Managing Users and Teams.

For more information on how to update to version 2, see Update Connector Version [page 2424].

> **Note**
>
> In SAP Analytics Cloud, groups are considered teams.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Analytics Cloud* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Analytics Cloud system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Analytics Cloud.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Analytics Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Analytics Cloud instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page. For more information, refer to *Authorize API Access for OAuth Clients* in Manage OAuth Clients
`sac.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. This property is automatically added to the system, with default value: **enabled** **Note** If the property is missing, its default value is **disabled**.

Property Name	Description & Value
(Optional) `sac.csrf.token.path`	Path which is appended to the URL to retrieve the CSRF token. The property is automatically added during system creation, when the system in use is SAP Analytics Cloud consuming SCIM API version 2. Based on the version of the SCIM API consumed, the default value for the property is: • SAP Analytics Cloud SCIM API version 1: `/api/v1/scim/Users?count=1` **Note** The property is present only for systems created before December 3, 2024. Systems created after this date use the default value for the connector version without adding the property. • SAP Analytics Cloud SCIM API version 2: `/api/v1/scim2/Users?count=1` **Note** If you delete the property, the Identity Provisioning will use the default value for the property for SAP Analytics Cloud using SCIM API **version 1**.

Property Name	Description & Value
`sac.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists in SAP Analytics Cloud. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). According to your use case, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Note** If this property is missing, or you've deleted it, and the service does not find such a *userName*, it will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is unsuccessful too, the creation of the conflicting user fails. For more information, see: List of Properties [page 80]
(Optional) `sac.api.version`	Handles the version of SAP Analytics Cloud SCIM API. **Possible values:** • *1* - Indicates that SAP Analytics Cloud SCIM API version 1 is used. • *2* - Indicates that SAP Analytics Cloud SCIM API version 2 is used. Default value: *1*

Property Name	Description & Value
(Optional) `sac.support.bulk.operation`	Set this property to *true* if you want to enable SCIM bulk operations for provisioning users. That means, the Identity Provisioning service can write, update, and delete a potentially large collection of users in a single request. For more information, see: SCIM Protocol: Bulk Operations If not specified, the default value is *false*. **Note** SCIM bulk operations are not supported for provisioning groups to SAP Analytics Cloud.
(Optional) `sac.bulk.operations.max.count`	If you have enabled the SCIM bulk operations, you can use this property to set the number of users to be provisioned per request. Default value: • **`100`** - when using SAP Analytics Cloud SCIM API version 1. • **`30`** - when using SAP Analytics Cloud SCIM API version 2. **Note** The value must not exceed the number of entities defined by the SAP Analytics Cloud system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Payload Too Large*).
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.http.header.x-ignore-roles-if-missing`	Use this property to control whether users or teams (referred to as groups) should keep their role assignments in SAP Analytics Cloud (SCIM API version 1) when no roles are provisioned. Possible values: • true - Users or teams will keep their role assignments when no roles are provisioned. • false - Users or teams will lose their role assignments when no roles are provisioned. This is the default value. For more information, see SAP note 3092730. In SAP Analytics Cloud (SCIM API version 2), this behavior is managed by `sac.support.patch.operation` property.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Analytics Cloud* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Analytic Cloud system. For more information, see: Manage Transformations [page 2439]

   SAP Analytics Cloud REST API: Managing Users and Teams

   Managing Users and Teams → api/v1/scim

   Managing Users and Teams → api/v1/scim2

   Default transformation for SAP Analytics Cloud SCIM API version 1:

   Code Syntax

```
{
    "user": {
        "condition": "isValidEmail($.emails[0].value) &&
(('%sac.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%sac.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "sourcePath": "$.schemas",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.schemas"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
```

```
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.emails[0].value",
                "targetPath": "$.userName"
            },
            {
                "condition": "$.emails[?(@.primary == true)].value != []",
                "sourcePath": "$.emails[?(@.primary == true)].value",
                "preserveArrayWithSingleElement": false,
                "optional": true,
                "targetPath": "$.userName"
            },
            {
              "sourcePath": "$.name.givenName",
              "targetPath": "$.name.givenName",
              "optional": true
            },
            {
              "sourcePath": "$.name.middleName",
              "targetPath": "$.name.middleName",
              "optional": true
            },
            {
              "sourcePath": "$.name.familyName",
              "targetPath": "$.name.familyName",
              "optional": true

custom-parameters']['description']"
      }
    ]
  }
}
```

⚠ Caution

When running a provisioning job to update users or teams (referred to as groups) with role assignments in SAP Analytics Cloud, these role assignments will be removed as a result of the update. This behavior, which can lead to permission issues, is expected because role assignments in SAP Analytics Cloud are not available as group parameters in some source systems, such as Identity Authentication. To preserve existing role assignments when updating users or teams, proceed as follows based on the version of the SAP Analytics Cloud SCIM API:

- For SCIM API version 1, set the `ips.http.header.x-ignore-roles-if-missing` property to *true* in the SAP Analytics Cloud target system. For more information, see the properties table above and the SAP note 3092730.
- For SCIM API version 2, set the `sac.support.patch.operation` property to *true* in the SAP Analytics Cloud target system.

ⓘ Note

Updating a user in SAP Analytics Cloud using SCIM API version 2 depends on whether user attributes in SAP Analytics Cloud are mapped to SAML attributes in your identity provider. If this is the case, the values of those attributes are populated by the identity provider and cannot be changed by the SAP Analytics SCIM API or the UI. For more information, see Mapping SAML Attributes to Users

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ⚠ Caution
>
> The **email** attribute is unique for *SAP Analytics Cloud* but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in *SAP Analytics Cloud*.
>
> To learn more, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from SAP Analytics Cloud target, see: Exclude Users from Provisioning to Target Systems

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

(Guided Answers) Multiple Users from a Source System Are Created as One in the Target

1.6.2.7 SAP Application Server ABAP

Follow this procedure to set up SAP Application Server ABAP (AS ABAP) as a target system.

Prerequisites

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector.
  For more information on how to make a connection to this on-premise system, follow the procedure in Connect to On-Premise Systems [page 2468].
- You have credentials of a technical user with write permissions for AS ABAP. Via this user, the Identity Provisioning service will call the ABAP public API in order to execute a number of function modules. These function modules are listed in **step 1** from the procedure below.
- The technical user must have the required RFC and security authorizations, as described in SAP Note 3666721.

> **Note**
>
> If the technical user has insufficient security authorization, no users or roles can be read.

Context

SAP Application Server ABAP (AS ABAP) offers a user store and user administration capabilities for maintaining users and their authorizations for AS ABAP applications. You can configure AS ABAP as a target system so as to provision new entities from another on-premise or cloud system.

> **Caution**
>
> You can't create or delete groups in AS ABAP. That means:
>
> - On the attempt to create a group in AS ABAP, Identity Provisioning will only add new members or update existing ones. Also, when the service reads a group from a source system, there must be a group with the exact same display name (case sensitive) in the AS ABAP target system. Otherwise, an error will be thrown and the group members will not be updated.
>   If group names in the source system differ from the ones in AS ABAP, you can define value mappings for these group names so the provisioning will still work. To learn how, see Transformation Expressions [page 391] → section **valueMapping**.
> - On the attempt to delete a group in AS ABAP, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

Groups in source systems are mapped to roles in AS ABAP target systems.

> **Note**
>
> Role unassignments are handled differently in AS ABAP version 7.31 and lower, and versions higher than 7.31. For example: If a child role R2 is assigned to a user – first, indirectly through a parent role R1, and then directly to the user, when the parent role is unassigned, expect the following results:
>
> AS ABAP **7.31 and lower**: Directly assigned parent role R1 and indirectly assigned child role R2 are unassigned. Directly assigned child role R2 is still assigned to the user.
>
> AS ABAP **higher than 7.31**: All roles are unassigned from the user.

Procedure

1. Open the Cloud Connector to add an access control system mapping for **AS ABAP**. This is needed to allow the Identity Provisioning service to access AS ABAP as a back-end system on the intranet. To learn how, see: Configure Access Control (RFC)

Go to *Cloud To On-Premise* > *Access Control* tab and select protocol *RFC SNC*. Then, expose the following *exact names* as accessible resources:

- `PRGN_ROLE_GETLIST`
- `BAPI_USER_GETLIST`
- `BAPI_USER_GET_DETAIL`
- `BAPI_USER_CREATE1`
- `BAPI_USER_ACTGROUPS_ASSIGN`
- `IDENTITY_MODIFY`
- `BAPI_USER_DELETE`
- `PRGN_ACTIVITY_GROUPS_LOAD_RFC`

These are Business Application Programming Interface (BAPI) functional modules designed to perform certain tasks in the SAP AS ABAP system, such as retrieving, creating, updating or deleting user data.

For more information about each function module and its parameters, refer to the documentation provided in the SAP system. Logon to your SAP system and run transaction code **SE37**. In the *Function Builder: Initial Screen*, enter the function name, choose *Display* and then *Functional Module Documentation*.

2. Open SAP BTP cockpit, and in your Identity Provisioning subaccount create a destination for the AS ABAP system. To learn how, see: Create RFC Destinations

   The destination configuration is required by the Identity Provisioning service to find the back-end system to be used for writing data. It also provides the credentials of the technical user, needed for the connection to the ABAP public API.

   Below are the fields you have to fill in the cockpit destination before using an AS ABAP client as a target system.

   > ### Note
   >
   > In the RFC destination, you can set only JCo properties. Properties starting with `abap` are connector specific and must be set in the Identity Provisioning UI.

Field/Property Name	Value
Name	Enter a destination name.
Type	Select *RFC*.
User	Enter the user for AS ABAP. The *User* field corresponds to property `jco.client.user` in the exported RFC destination.
Password	(Credential) Enter the password for the AS ABAP user. The *Password* field corresponds to property `jco.client.passwd` in the exported RFC destination.

Field/Property Name	Value
jco.client.client	The property is configured during destination creation in SAP BTP cockpit. Provide the client to be used in the ABAP system. Valid format is a three-digit number.
Proxy Type	Defines the proxy type of the connection you need to provide for your ABAP system. The value is set during destination creation in SAP BTP cockpit. The proxy type *OnPremise* requires the Cloud Connector to access resources within your on-premise network. Enter: *OnPremise*
Direct Connection	
jco.client.ashost	Provide the virtual host entry that you have configured in the Cloud Connector → *Access Control* configuration. At least one property specifying the target host must be set during destination creation.
jco.client.sysnr	Provide the "system number" of the ABAP system.
Load Balancing Connection	
jco.client.mshost	Represents the message server host to be used. At least one property specifying the target host must be set during destination creation.
jco.client.r3name	Provide the three-character system ID of the ABAP system to be addressed.
jco.client.msservt	Provide the port on which the message server is listening for incoming requests. You can use this property as an alternative to `jco.client.r3name`.
Optional Properties	
`jco.destination.peak_limit`	The value represents the maximum number of active connections that can simultaneously be created for a destination. For example: *10*
`jco.destination.pool_capacity`	The value represents the maximum number of idle connections kept open by the destination. For example: *5*

Field/Property Name	Value
`ips.overwrite.existedbefore.assignments`	This property defines whether or not the Identity Provisioning service to overwrite user/group assignments that have existed in the target system before you start provisioning entities to that system. • If you start a provisioning job without setting this property (by default, it's *true*), all assignments from the source group will overwrite the ones from the target group. • If you set the property to *false*, all existing assignments will be kept in the target system group, and the new ones will just be added.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
`ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

> **Note**
>
> If connection properties, like `User` and `Password`, are configured both in the destination (SAP BTP cockpit) and on the *Properties* tab (Identity Provisioning User Interface), the values set in the destination are considered with higher priority.

3. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
4. Add *SAP Application Server ABAP* as a target system. To learn how, see: Add New Systems [page 2415]
5. From the *Destination Name* dropdown, choose the RFC destination you have created in *step 2*.
6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Application Server ABAP* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in AS ABAP. For more information, see Manage Transformations [page 2439].

> **Note**
>
> The value of the **entityIdTargetSystem** attribute stores the entity's unique ID, which is written in the target system as the value of the **USERNAME** attribute. Do not delete or change this statement!

When AS ABAP is configured as a target system for the Identity Provisioning service, the ABAP public API is used to write the identity data retrieved from the relevant source system. During the writing process, the JSON data is following the structure of the export parameters and will turn them into list and tables. Therefore, every JSON array from the intermediate transformation will be represented as a BAPI table, and every child JSON object will be represented as a BAPI structure.

Default transformation:

- Use the default transformation if the version of your AS ABAP system is *7.40* or higher. If your system version is *7.31*, you can still use this transformation – just apply SAP Note 1695883.
  Note: *Active* and *inactive* users are handled as follows:
  - If a user is *inactive* in the source system, Identity Provisioning creates it as *inactive* (locked) in AS ABAP target system too.
  - If a user is *active* in the source system, Identity Provisioning sets the `LOCK` value to `"U"` when updating the user in the AS ABAP target system.
  - If a user is *inactive* in the source system, Identity Provisioning sets the `LOCK` value to `"L"` when updating the user in the AS ABAP target system.

            "minimumNumberOfDigits": 1,
            "minimumNumberOfSpecialSymbols": 0
          }
        ]
      },
      {
        "constant": "updateEntity",
        "targetVariable": "operationTypeVariable"
      },
      {
        "constant": "createEntity",
        "targetVariable": "operationTypeVariable",
        "scope": "createEntity"
      },
      {
        "condition": "$.active == false && '${operationTypeVariable}'
== 'createEntity'",
        "constant": "X",
        "targetPath": "$.LOCK_LOCALLY"
      },
      {
        "condition": "'${operationTypeVariable}' == 'updateEntity'",
        "constant": "U",
        "targetPath": "$.LOCK"
      },
      {
        "condition": "$.active == false && '${operationTypeVariable}'
== 'updateEntity'",
        "constant": "L",
        "targetPath": "$.LOCK"
      }
    ]
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
abap.role.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
abap.role.prefix) && (isRegularGroup() ||
isApplicationSpecificGroup())",
    "mappings": [
      {
        "scope": "createEntity",
        "sourcePath": "$.displayName",
        "targetVariable": "entityIdTargetSystem",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
abap.role.prefix)",
            "function": "replaceFirstString",
            "regex": "%abap.role.prefix%",
            "replacement": ""
          }
        ]
      },
```

```
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.ROLE_NAME",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
abap.role.prefix)",
            "function": "replaceFirstString",
            "regex": "%abap.role.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.USERLIST[?(@.USERNAME)]",
        "optional": true,
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

7. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

ABAP: Supported Languages and Code Pages

1.6.2.8 SAP Ariba Applications

Follow this procedure to set up SAP Ariba Applications as a target system.

Prerequisites

> **Note**
>
> This topic describes customer-managed configurations for the SAP Ariba Applications target system. For SAP-managed configurations, refer to the SAP-Managed SAP Cloud Identity [page 520] documentation.

Next-Generation SCIM API

If you are using the next-generation SCIM API provided by SAP Ariba Applications:

- The Identity Provisioning service must be configured to use the OAuth 2.0 client-credentials flow to obtain access tokens from the Identity Authentication service for calling the SAP Ariba Applications next generation SCIM API. The required dependency must be defined in the configuration of the consumer application. For more information, see Configure Form-Based OAuth Authentication [page 2457].

Current-Generation SCIM API

If you are using the current-generation SCIM API provided by SAP Ariba Applications:

- You have created a client application on SAP Ariba APIs Portal for your integration with Identity Provisioning. This is needed to enable SCIM API for user and group for Ariba Applications. For more information, see Register an Application in SAP Ariba Developer Portal .

  > **Note**
  >
  > If you don't have an SAP Ariba APIs account, go to the SAP Ariba Developer Portal and follow the instructions for sign up. For more information, see Get an SAP Ariba APIs Account.

  To find your *realm* name, log in to your SAP Ariba system. It is embedded in your login URL, as illustrated by the following examples:
  - SAP Ariba Buyer example: `https://s1.ariba.com/Buyer/Main/ad/loginPage/...&realm=`*`mycompany-t`*
  - SAP Ariba Sourcing example: `http://`*`mycompany`*`.sourcing.ariba.com/`
- You have enabled the client application for Identity Provisioning on the SAP Ariba Developer Portal.
- You have generated an OAuth secret for your application. For more information, see Generating the OAuth Secret and Base64 Encoded Client ID and Secret.
  To set up your SAP Ariba Applications provisioning system, you'll need to map your SAP Ariba application parameters to the corresponding Identity Provisioning properties. The mapping is as follows:

SAP Ariba	Identity Provisioning	Values
SCIM API URL	URL	Examples:

SAP Ariba	Identity Provisioning	Values
		• US: **https://openapi.ariba.com** • Europe: **https://eu.openapi.ariba.com** • UAE: **https://mn1.openapi.ariba.com** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
SAP Ariba OAuth 2.0 Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token** • UAE: **https://api.mn1.ariba.com/v2/oauth/token** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
OAuth Client ID	`User`	Alphanumeric string Example: **aaaa12345-1111-3333-cccc-1234567890**
OAuth Secret	`Password`	Alphanumeric string Example: **aaaGGG1eee12abcdefGHIJK123lmnopTTT**
Application key	`ariba.applications.api.key`	Alphanumeric string Example:**123abc123XYZ000abc123ABC012345**
AN-ID	`ariba.applications.realm.id`	AN<numeric_string> Example: **AN000111222333**

Context

After fulfilling the prerequisites, you can create an SAP Ariba Applications target system to provision users and groups.

These target systems can consume either the current-generation SCIM API or the next-generation SCIM API provided by SAP Ariba Applications. Identity Provisioning distinguishes between the two by the API URL pattern (the current SCIM API contains **openapi** in the URL, while the next-generation API does not) and by the `AuthType=Form` property, which must be configured only for the next-generation API.

For more information about the SAP Ariba SCIM API scope of support, see SAP Ariba SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Ariba Applications* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SCIM API URL for your SAP Ariba application (see the **Prerequisites** section). The current-generation SCIM API uses the **openapi** pattern in the URL.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`AuthType`	Enter: *Form* **Relevant for next-generation SCIM API**
`User`	Enter the *Client ID* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`Password`	(Credential) Enter the *Client Secret* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.

Property Name	Description & Value
`ariba.applications.api.dependency.name`	This property holds the value of the dependency name used in the configuration of the SAP Ariba Applications consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. **Relevant for next-generation SCIM API**
`ariba.applications.api.key`	(Credential) Enter your application key (see the **Prerequisites** section). **Relevant for current-generation SCIM API**
`ariba.applications.realm.id`	Enter your AN-ID (see the **Prerequisites** section). **Relevant for current-generation SCIM API**
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Exemplary destination (property configuration):

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://openapi.ariba.com
User=aaaa12345-1111-3333-cccc-1234567890
Password=**********
OAuth2TokenServiceURL=https://api.ariba.com/v2/oauth/token
ariba.applications.api.key=123abc123XYZ000abc123ABC012345
ariba.applications.realm.id=AN000111222333
```

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Applications* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Applications. For more information, see:

   Manage Transformations [page 2439]

   SCIM API for User and Group Master Data

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "('%ariba.applications.group.prefix%' === 'null') ||
($.groups[?(@.display =~ /%ariba.applications.group.prefix%.*/)] empty
false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",

          }
        ]
      }
    ]
  }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.9 SAP Ariba Category Management

Follow this procedure to set up SAP Ariba Category Management as a target system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Category Management. For more information, see Creating a SAP Ariba Category Management SCIM Service Instance in Your Subaccount.

> **Note**
>
> This connector has been deprecated as of August 25, 2025, and is no longer needed. Customers with existing configurations should stop running jobs to or from SAP Ariba Category Management provisioning systems.

Context

SAP Ariba Category Management is a cloud-based solution that enables organizations to define and manage purchasing categories and provides actionable market intelligence, category insights, and various tools and templates for developing and operationalizing category strategies that drive business value and performance. This business solution is built on SAP Business Technology Platform (BTP). You can use Identity Provisioning to configure SAP Ariba Category Management as a target system where you can provision users from source systems.

> **Note**
>
> SAP Ariba Category Management does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.

2. Add *SAP Ariba Category Management* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token`
(Optional) `cm.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. Possible values: *userName* and *emails[*].value* For more information, see: **User Update and Uniqueness** section below and List of Properties [page 80].
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Category Management* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Category Management system. For more information, see:

Manage Transformations [page 2439]

SCIM APIs for SAP Ariba Category Management

Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Ariba Category Management entity.

User Update and Uniqueness

The write transformation of SAP Ariba Category Management supports two user unique attributes for managing conflict resolution: *username* and *email*. The username is a mandatory attribute, while the email is an optional, multivalue attribute, indicating that a user may have multiple unique emails.

The uniqueness of a user in the target system is determined not only by the individual attributes or the combination of both, but also by considering whether one or multiple existing users in the target system share the same values for these unique attributes. Have in mind the following specifics when updating an existing user in the target system, in accordance with the configuration of the `cm.user.unique.attribute` property:

- When `cm.user.unique.attribute`= *userName*
  If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same email, but a different userName, the user provisioning will fail. In this case, Identity Provisioning will try to create a new user but will fail, since a user with the same email already exists.
- When `cm.user.unique.attribute`= *emails[*].value*
  If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same username, but a different email, the user provisioning will fail. In this case, Identity Provisioning will try to create a new user but will fail, since a user with the same username already exists.
- When `cm.user.unique.attribute`= *userName, emails[*].value*
  - If a user in the source system, with a specific username and multiple emails, matches an existing user in the target system by the same username and at least one identical email, the user in the target system will be updated.
  - If a user in the source system, with a specific username and multiple emails, matches multiple existing users in the target system (each sharing one of the multiple emails but having different usernames), the user provisioning will fail. In this case, the user will neither be created nor updated.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]",
```

```
                "preserveArrayWithSingleElement": true
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath":"$.externalId",
                "targetPath":"$.externalId",
                "optional":true
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "optional": true
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true,
                "defaultValue": true
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "optional":true,
                "preserveArrayWithSingleElement": true
            }
        ]
    }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

User Replication Setup

1.6.2.10 SAP Ariba Central Invoice Management

Follow this procedure to set up SAP Ariba Central Invoice Management as a target system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Central Invoice Management. This step is automated by the booster *Set Up SAP Ariba Central Invoice Management*. For more information, see Setting Up Invoice Processing with SAP Ariba Central Invoice Management (4N6) –> *Set up Configuration Using Booster in SAP BTP Cockpit*.

Context

SAP Ariba Central Invoice Management is an SAP BTP SaaS application running on SAP BTP, Cloud Foundry environment. This application enables central management of supplier invoices from multiple connected systems, such as SAP S/4HANA Cloud Public Edition systems. You can use Identity Provisioning to configure SAP Ariba Central Invoice Management as a target system where you can provision users and groups from source systems.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Ariba Central Invoice Management* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
Type	Enter: *HTTP*

Property Name	Value
`URL`	Enter the URL provided by the service key under the *ips-connector* field without adding the path information. For example: `https://eu10.cim.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token` For example: `https://<my tenant>.authentication.eu10.hana.ondemand.com/oauth/token`
(Optional) `cim.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. **Possible values:** • *userName* - default value • *emails[*].value* • *userName,emails[*].value* For more information, see: List of Properties [page 80]
(Optional) `cim.group.prefix`	This property distinguishes SAP Ariba Central Invoice Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`CIM_`** You can use the example value or provide your own. When **set in the target system**, only groups containing the **`CIM_`** prefix in their display name will be provisioned to SAP Ariba Central Invoice Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Ariba Central Invoice Management.

Property Name	Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Central Invoice Management* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Central Invoice Management system. For more information, see:

   Manage Transformations [page 2439]

   User Management (SCIM) for SAP Ariba Central Invoice Management

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Ariba Central Invoice Management entity.

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "(($.emails EMPTY true) ||
(isValidEmail($.emails[*].value))) && (('%cim.group.prefix%' === 'null')
|| ($.groups[?(@.display =~ /%cim.group.prefix%.*/)] empty false))",
    "mappings": [
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User"
        ],
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
```

```
      "sourcePath": "$.userName",
      "targetPath": "$.userName"
    },
    {
      "sourcePath": "$.externalId",
      "targetPath": "$.externalId",
      "optional": true
    },
    {
      "sourcePath": "$.name.givenName",
      "targetPath": "$.name.givenName",
      "optional": true
    },
    {
      "sourcePath": "$.name.middleName",
      "targetPath": "$.name.middleName",
      "optional": true
    },
    {
      "sourcePath": "$.name.familyName",
      "targetPath": "$.name.familyName",
      "optional": true
    },
    {
      "sourcePath": "$.name.formatted",
      "targetPath": "$.name.formatted",
      "optional": true
    },
    {
      "sourcePath": "$.name.honorificPrefix",
      "targetPath": "$.name.honorificPrefix",
      "optional": true
    },
    {
      "sourcePath": "$.name.honorificSuffix",
      "targetPath": "$.name.honorificSuffix",
      "optional": true
    },
    {
      "sourcePath": "$.emails",
      "preserveArrayWithSingleElement": true,
      "optional": true,
      "targetPath": "$.emails"
    },
    {
      "condition": "$.emails[?(@.primary == true)] empty true",

          }
        ]
      }
    ]
  }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Ariba Central Invoice Management

1.6.2.11 SAP BTP ABAP environment

Follow this procedure to set up SAP BTP ABAP environment as a target system.

Prerequisites

To establish the connection between Identity Provisioning and SAP BTP ABAP environment, you need to set up the communication (user, system and arrangement) on SAP BTP ABAP environment. You can do it now (as a prerequisite) or in the process of configuring SAP BTP ABAP environment as a target system, as described in step 3.

Context

You can use SAP BTP ABAP environment as a target system to provision entities from a certain source system. This scenario supports writing **users** and **assignments**. In SAP BTP ABAP environment, groups correspond to roles, thus group members are user assignments of a role.

> ### Note
>
> Identity Provisioning cannot create and delete roles in SAP BTP ABAP environment target system. It can only create, update and delete user assignments of a role. Therefore, roles must have been created in SAP BTP ABAP environment target system before you run a provisioning job.
>
> For example, if you try to create or delete a role in SAP BTP ABAP environment, Identity Provisioning will only add or remove the user assignments of that role, respectively.

The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users** (Employee).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP BTP ABAP environment* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP BTP ABAP environment and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP BTP ABAP environment target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP BTP ABAP environment backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

For more information, see Maintain a Communication Arrangement for Inbound Communication

> **Note**
>
> The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
>
> The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP BTP ABAP environment system. You can take the URL from the communication scenario SAP_COM_0193.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`ips.date.variable.format`	*yyyy-MM-dd*
`a4c.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP BTP ABAP environment target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID*

Property Name	Description & Value
`a4c.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP BTP ABAP environment target system. • **true** – the current user roles will be deleted in the target system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* See also: Extended Explanation of the *.user.roles.overwrite Properties
(Optional) `a4c.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*.
(Optional) `a4c.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20).
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of user assignments of a role, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://12345-aaaaa-3333.abap.hana.ondemand.com*

`User`=*MyABAPEnvUser*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`a4c.user.roles.overwrite`=*false*

`a4c.support.bulk.operation` = *true*

`a4c.bulk.operations.max.count` = *50*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP ABAP environment* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in SAP BTP ABAP environment. For more information, see:

   Manage Transformations [page 2439]

   Inbound Service: Business User

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "isValidEmail($.emails[0].value) &&
(('%a4c.roles.prefix%' === 'null') || ($.groups[?(@.display =~ /
%a4c.roles.prefix%.*/)] empty false))",
```

```
    "mappings": [
      {
        "sourcePath": "$.userName",
        "targetPath": "$.personExternalID"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.personExternalID",
        "optional": true
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['employeeNumber']",
        "targetPath": "$.personExternalID",
        "optional": true
      },
      {
        "targetPath": "$.personID",
        "sourceVariable": "entityIdTargetSystem"
      },

        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.personalInformation.lastName"
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.personalInformation.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.formatted",
        "targetPath": "$.personalInformation.personFullName",
        "optional": true
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.user.userName"
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.user.logonLanguageCode",
        "optional": true
      },
      {
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.workplaceInformation.emailAddress"
      },
      {
        "targetPath": "$.user.lockedIndicator",
        "constant": "false"
      },
      {
        "condition": "$.active == false",
        "targetPath": "$.user.lockedIndicator",
        "constant": "true"
      }
    ]
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
a4c.roles.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
a4c.roles.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "mappings": [
      {
        "sourcePath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
a4c.roles.prefix)",
            "function": "replaceFirstString",
            "regex": "%a4c.roles.prefix%",
```

```
            "replacement": ""
          }
        ],
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
a4c.roles.prefix)",
            "function": "replaceFirstString",
            "regex": "%a4c.roles.prefix%",
            "replacement": ""
          }
        ],
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

See also: Extended Explanation of the *user.roles.overwrite Properties

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

User Provisioning in SAP BTP ABAP environment

1.6.2.12 SAP BTP Account Members (Neo)

Follow this procedure to set up your SAP Business Technology Platform as a target system, to which you can provision and write members in your Neo account.

Prerequisites

You have created a new Platform API OAuth client, with API *Account Member Management* and scopes *Manage Account Members* and *Read Account Members*.

Save the *Client ID* and *Client Secret* as you'll need them when you configure your target system. Make sure you save the client secret as you cannot retrieve it later.

For more information, see Create a Platform API Client.

Context

The Identity Provisioning service helps companies to automatically manage the user-to-platform roles assignments for SAP Business Technology Platform subaccounts. For this aim, the service reuses data from an active company user store. For this scenario, as a target system are used SAP Business Technology Platform subaccounts. A source system can be a solution supported by the Identity Provisioning service with read access for user artifacts.

This provisioning scenario is based on the Platform Authorization Management API of SAP BTP. For more information, see Platform Authorization Management API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP BTP Account Members (Neo)* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
URL	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/platform/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_CP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*
`scp.user.userbase`	This property specifies the host to the identity provider to be used with this proxy system. All provisioned users can be authenticated only by this identity provider. Default value: *accounts.sap.com* If you use another IdP, enter its value as configured in the SAP BTP cockpit. For example: **`<account_ID>.accounts.ondemand.com`**
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Account Members* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Using the default transformation, all groups that are available in the source system and their respective members (as identifiers) are assigned as platform roles to the users. These users are added to the SAP Business Technology Platform subaccount via the target system.

   You can change the default transformation mapping rules to reflect your current setup of entities in your target system. For more information, see:

   Manage Transformations [page 2439]

   SAP BTP: Authorization Management API

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "('%scp.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%scp.group.prefix%.*/)] empty false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
// The roles in the conditions below are placeholder names mapped to the
SAP BTP roles. You can replace these names with the actual role names used
in your source system.
// You can delete some of these roles (if redundant), or add new mappings
for additional roles.
      {
        "condition": " (('%scp.group.prefix%' === 'null')
&& ($.groups[*].value contains 'AccountAdministrator')) ||
(('%scp.group.prefix%' !== 'null') && ($.groups[*].value contains
'%scp.group.prefix%AccountAdministrator'))",
        "constant": "AccountAdministrator",
        "targetPath": "$.roles[0].value"
      },
```

```
      {
        "condition": " (('%scp.group.prefix%' === 'null') &&
($.groups[*].value contains 'Developer')) || (('%scp.group.prefix%' !==
'null') && ($.groups[*].value contains '%scp.group.prefix%Developer'))",
        "constant": "Developer",
        "targetPath": "$.roles[1].value"
      },
      {
        "condition": " (('%scp.group.prefix%' === 'null')
&& ($.groups[*].value contains 'CloudConnectorAdministrator')) ||
(('%scp.group.prefix%' !== 'null') && ($.groups[*].value contains
'%scp.group.prefix%CloudConnectorAdministrator'))",
        "constant": "CloudConnectorAdministrator",
        "targetPath": "$.roles[2].value"
      },
      {
        "condition": " (('%scp.group.prefix%' === 'null')
&& ($.groups[*].value contains 'ApplicationUserAdministrator')) ||
(('%scp.group.prefix%' !== 'null') && ($.groups[*].value contains
'%scp.group.prefix%ApplicationUserAdministrator'))",
        "constant": "ApplicationUserAdministrator",
        "targetPath": "$.roles[3].value"
      },
      {
        "condition": " (('%scp.group.prefix%' === 'null') &&
($.groups[*].value contains 'ReadOnly')) || (('%scp.group.prefix%' !==
'null') && ($.groups[*].value contains '%scp.group.prefix%ReadOnly'))",
        "constant": "ReadOnly",
        "targetPath": "$.roles[4].value"
      },
      {
        "constant": "%scp.user.userbase%",
        "optional": true,
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:UserExt']['userbase']"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
        "targetPath": "$.schemas[0]"
      },
      {
        "constant":
"urn:sap:cloud:scim:schemas:extension:custom:2.0:UserExt",
        "targetPath": "$.schemas[1]"
      }
    ]
  },
 "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
scp.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
scp.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "skipOperations": [
      "delete"
    ],
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
scp.group.prefix)",
            "function": "replaceFirstString",
```

```
            "regex": "%scp.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "sourcePath": "$.members[*].value",
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "type": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

What is SAP BTP

1.6.2.13 SAP BTP Platform Members (Cloud Foundry)

Follow this procedure to set up a SAP BTP Platform Members (Cloud Foundry) as a target system.

Prerequisites

- You have a global account in SAP BTP with at least one multi-environment subaccount with enabled Cloud Foundry environment.
- You have added SAP BTP Platform Members (Cloud Foundry) as a source system for the same Cloud Foundry landscape and executed successfully a read job, typically to the Identity Directory of the SAP Cloud Identity Services tenant that is established as a trusted custom identity provider.

This is required to preserve the specific group naming convention (see the defined name pattern below) used by SAP BTP Platform Members (Cloud Foundry). Reading groups from this source into the Identity Directory, assigning users to the groups, and synchronizing the assignments back to SAP BTP Platform Members (Cloud Foundry) ensures the correct provisioning of user group assignments. For more information, see SAP BTP Platform Members (Cloud Foundry) source system [page 674] and Local Identity Directory target system [page 957].

Context

The Cloud Foundry environment enables you to create polyglot cloud applications in Cloud Foundry. It contains the SAP BTP, Cloud Foundry runtime service, which is based on the open-source application platform managed by the Cloud Foundry Foundation. For more information, see Cloud Foundry Environment.

When you enable the Cloud Foundry environment in your subaccount, the system automatically creates a Cloud Foundry organization for you. You are able to add platform users as org members and space members and assign roles to grant these users platform access. For more information, see Valid role types .

SAP BTP Platform Members (Cloud Foundry) connector manages org and space members, as well as their role assignments, in the Cloud Foundry environment of a multi-environment subaccount, where a **single** SAP Cloud Identity Services tenant acts as custom identity provider. We recommend that you use the Identity Provisioning service enabled in this SAP Cloud Identity Services tenant.

In SAP BTP Platform Members (Cloud Foundry), groups correspond to roles in particular Cloud Foundry orgs or spaces, thus group members are user assignments of a role in a specific Cloud Foundry org or space. Group names must follow a defined pattern, explained below, to ensure the correct mapping and provisioning of users and their role assignments to the relevant Cloud Foundry organization or space.

> **Note**
>
> The attribute *name*, defined within the *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group* schema, is used to map the users and user assignments of a role to the relevant Cloud Foundry organization or space. The group names follow the respective patterns:
>
> - organization group name: `<org_ID> <org_role>`
> - space group name: `<org_ID> <space_ID> <space_role>`, where `space_ID` can be retrieved using the Cloud Foundry Command Line Interface by executing the command **`cf space --guid`**.
>
> Whereas the group display names adhere to the following patterns:
>
> - organization group display name: `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<org_role>`
> - space group display name: `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<space_name>:<space_role>`

The target system consumes `User Account and Authentication API` and `Cloud Foundry V3 API` provided by Cloud Foundry.

→ Remember

This connector enables you to write users and user role assignments to Cloud Foundry on *subaccount* level. For provisioning of users and groups to Cloud Foundry on *application* level, refer to SAP BTP XS Advanced UAA (Cloud Foundry) [page 1045]. For more information, see SAP BTP Integration Scenario.

ⓘ Note

The number of platform users you can provision is limited, as specified in the restriction described in User Provisioning.

Follow the steps below to create SAP BTP Platform Members (Cloud Foundry) as a target system to provision users and user role assignments.

ⓘ Note

In case you have Cloud Foundry environment enabled in multiple Cloud Foundry landscapes or more than one SAP Cloud Identity Services tenants, you must configure a separate SAP BTP Platform Members (Cloud Foundry) connector for each of them.

Procedure

1. To enable provisioning of platform users and user role assignments to and from Cloud Foundry environment, create a Support Ticket on component `BC-CP-CF-SEC-IAM`.

   Specify your SAP Cloud Identity Services tenant ID and the origin key of the trust configuration for BTP platform users which points to your SAP Cloud Identity Services tenant. You can find the origin key value in the SAP BTP cockpit. Go to your SAP BTP subaccount, choose *Trust Configuration* and see the value under *Origin Key* for the relevant *Custom Identity Provider for Platform Users*.
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *SAP BTP Platform Members (Cloud Foundry)* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the `email` of the CF provisioning user (see **Prerequisites**).

Property Name	Description & Value
`Password`	(Credential) Enter the password for the CF provisioning user (see **Prerequisites**).
`btp.cf.pm.origin`	Enter the origin key of your SAP Cloud Identity Services tenant (see **Step 1**). The value of this property is a string, which always ends with the suffix *-platform*. It will be used as the *origin* attribute in the system transformation.
`btp.cf.pm.landscape`	Enter the *technical key* or the *host name* of the landscape in which your multi-environment subaccount with enabled Cloud Foundry environment is located. The technical key is available only for the SAP BTP Cloud Foundry regions. For more information, see Regions and API Endpoints Available for the Cloud Foundry Environment. Please note that when the technical key contains an extension index, the correct value is displayed in the *API Endpoint* column instead of the *Technical Key* column of the table. This is an example of a *technical key*: **`cf-eu10-002`**, corresponding to the API endpoint `api.cf.eu10-002.hana.ondemand.com` and host name `cf.eu10-002.hana.ondemand.com` The host name of the landscape can be found by looking up the *API Endpoint* field in the *Overview* tab of your *Cloud Foundry Environment* on subaccount level of the SAP BTP cockpit. The API endpoint has the following format: `https://api.<landscape-hostname>` **Note** If your provisioning job finishes with error *'Name or service not known'*, the value used for technical key is not correct. In that case you can use the host name of the landscape instead.

Property Name	Description & Value
(Optional) `btp.cf.pm.group.prefix`	This property distinguishes SAP BTP Platform Members (Cloud Foundry) groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`BTP_CF_PM_`** When set in the target system, only groups containing the **`BTP_CF_PM_`** prefix in their display name will be provisioned to SAP BTP Platform Members (Cloud Foundry). Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP BTP Platform Members (Cloud Foundry).
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.trace.failed.entity.content`	If a provisioning job repeatedly fails and you need problem investigation, you can enable logging and tracing for the personal and sensitive data of your provisioned entities. To do this, set this property to *true*. For more information, see List of Properties [page 80].

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Platform Members (Cloud Foundry)* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP Platform Members (Cloud Foundry) system. For more information, see:

   Manage Transformations [page 2439]

   Cloud Foundry V3 API

- **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the SAP BTP Platform Members (Cloud Foundry) target attributes.
- **User offboarding** – If a user has been deleted from the source system, this change is recognized, and the user is deleted from the SAP BTP Platform Members (Cloud Foundry) target system too.

> ### Note
>
> Update operation is skipped for users in the default write transformation.

> ### Caution
>
> Keep in mind that when you add or delete users and user role assignments in SAP BTP Platform Members (Cloud Foundry), the operations order must adhere to the Cloud Foundry Environment hierarchy. In this case, you can expect the following behavior:
>
> - When adding a user as space member, it must already be present as member of the relevant organization with assigned role **Org User**. When deleting an org member, it should be first removed from the spaces of the relevant organization. In case you end up with erroneous entity structure, you can manually add or delete users via the administration console for SAP Cloud Identity Services.
> - When adding user role assignments, you should first add the org roles and afterwards proceed with the space roles. Also, when deleting user role assignments, you should first delete the space roles and then proceed with the org roles. If this condition is not fullfiled the job will finish with error. In that case, you can rerun the job until it finishes successfully.

Default transformation:

> ### Code Syntax

```
{
  "user": {
    "skipOperations": [
      "update"
    ],
    "condition": "(('%btp.cf.pm.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%btp.cf.pm.group.prefix%%btp.cf.pm.landscape%.+/)] empty
false)) && $.groups[?(@.display === 'cf-user-provisioning')] empty true",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },

        "targetPath": "$.verified"
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "condition": "$.emails[?(@.primary == true)].value == []",
        "targetPath": "$.emails[0].primary",
        "constant": true
      },
      {
        "constant": [
          "urn:scim:schemas:core:1.0"
        ],
        "targetPath": "$.schemas"
      }
    ]
  },
  "group": {
    "condition": "('%btp.cf.pm.group.prefix%' === 'null') ||
($.displayName =~ /%btp.cf.pm.group.prefix%%btp.cf.pm.landscape%.+/)",
    "mappings": [
      {
        "scope": "createEntity",
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "targetPath": "$.id",
        "targetVariable": "entityIdTargetSystem"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.members[*].value",
        "targetPath": "$.members[?(@.value)]",
        "optional": true,
        "preserveArrayWithSingleElement": true,
```

```
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

6. Now, add a source system from which to read users and user role assignments. For example: Local Identity Directory [page 604]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP BTP Integration Scenario

1.6.2.14 SAP BTP Java/HTML5 apps (Neo)

Follow this procedure to set up SAP Business Technology Platform as a target system, to which you can provision user-to-groups assignments for Java/HTML5 applications that run on SAP BTP, Neo environment.

Prerequisites

You have created a new Platform API OAuth client, with *Authorization Management* scopes. Save the *Client ID* and *Client Secret* as you'll need them when you configure your target system. Make sure you save the client secret as you cannot retrieve it later.

For more information, see Create a Platform API Client.

Context

The Identity Provisioning service helps companies to automatically manage the user-to-groups assignments for Java/HTML5 applications running on SAP BTP, Neo environment. For this aim, the service reuses data from

an active company user store. For this scenario, SAP BTP is the target system. The source system can be a solution supported by the Identity Provisioning service with read access for user and group artifacts.

This provisioning scenario is based on the Authorization Management REST API of SAP BTP. For more information, see Using the Authorization Management REST API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP BTP Java/HTML5 apps (Neo)* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_BTP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*

Property Name	Description & Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Java/HTML5 apps (Neo)* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Using the default transformation, all groups that are available in the source system and their respective members (as identifiers) will be created as groups and members in the SAP BTP account. In the target system, they will be configured and assigned to the same list of users (as identities) that are available as members for these roles in the source system.

   > ### Note
   >
   > Make sure the *group* mapping in the source system is enabled. If it contains **`"ignore": true`**, change it to **`"ignore": false`**.

   You can change the default transformation mapping rules to reflect your current setup of entities in your target system. For more information, see:

   Manage Transformations [page 2439]

   SAP BTP: Authorization Management API

   Default transformation:

   > ### Code Syntax

```
{
    "user": {
        "ignore": true,
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetVariable": "entityIdTargetSystem"
            }
        ]
    },
```

```
    "group": {
    "condition": "('%hcp.group.prefix%' === 'null') || ($.displayName =~ /
%hcp.group.prefix%.*/)",`
        "mappings": [
// Attribute entityIdTargetSystem stores the displayName attribute as a
unique value of the group.
                "sourcePath": "$.displayName",
                "targetVariable": "entityIdTargetSystem",
                "functions": [
                  {
                    "condition": "('%hcp.group.prefix%' !== 'null') && (@
=~ /%hcp.group.prefix%.*/)",
                    "function": "replaceFirstString",
                    "regex": "%hcp.group.prefix%",
                    "replacement": ""
                  }
              ]
            },
// All members of a source group will be transformed, by default, into
users for a new group.
// This group will be created in SAP BTP when the JSON data is prepared to
be sent to the target system.
            {
                "sourcePath": "$.members[*].value",
                "optional": true,
                "targetPath": "$.users"
            }
        ]
    }
}
```

5. Now, add a source system from which to read groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

What is SAP BTP

1.6.2.15 SAP BTP XS Advanced UAA (Cloud Foundry)

Follow this procedure to set up the SAP BTP XS Advanced UAA (running on SAP BTP, Cloud Foundry environment) as a target system.

Prerequisites

You have created credentials to call the REST APIs of the SAP Authorization and Trust Management service on global account, subaccount, or directory level. For more information, see: Get Access to the APIs and btp create security/api-credential.

Context

The SAP BTP XS Advanced UAA connector enables you to provision platform users, business users, groups and group assignments to the local user stores of global accounts, directories, and multi-environment subaccounts on SAP BTP. These users and groups (considered role collections in SAP BTP), are typically read from source systems, such as identity providers like SAP Cloud Identity Services.

Create a separate target system for each global account, subaccount and directory, and configure the respective credentials and connectivity properties. Depending on where you want to provision your entities, you need to:

- Create a target system for the global account to provision **platform users** and groups.
- Create a target system for the directory to provision **platform users** and groups.
- Create a target system for the subaccount to provision **platform users**, **business users** and groups.

> **Note**
>
> Provisioning of platform users as **org members** and **space members** requires the usage of a different connector: SAP BTP Platform Members (Cloud Foundry). For more information, see SAP BTP Platform Members (Cloud Foundry) [page 1034].

Creating, updating, and deleting groups follow the standard processes. If groups exist in the source but do not exist in the target, Identity Provisioning will create them. If groups have been changed or deleted in the source, Identity Provisioning will update or delete them accordingly. Deleting involves deassigning the group members and deleting the group itself.

Follow the steps below to create SAP BTP XS Advanced UAA as a target system to provision SAP BTP users and groups to global accounts, directories, and multi-environment subaccounts on SAP BTP.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.

2. Add *SAP BTP Advanced UAA (Cloud Foundry)* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the API URL in the following format: `https://api.authentication.<region>.hana.ondemand.com` For more information, see Call an API.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service in the following format: • `https://<global_account_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` • `https://<subaccount_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` • `https://<directory_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` For more information, see Call an API.
`User`	Enter the respective OAuth client ID that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.
`Password`	(Credential) Enter the respective OAuth client secret that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.

Property Name	Description & Value
`xsuaa.origin`	Enter the Origin Key of your identity provider. • Identity provider for platform users: In the SAP BTP cockpit, go to your global account (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for platform users. This origin key always ends with `-platform`. • Identity provider for business users: In the SAP BTP cockpit, go to your subaccount (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for business (application) users. For example: sap.custom **Note** If multiple origins are configured, the user will be created multiple times, once per origin. For more information, see Configure Single and Multiple Origins [page 1051]
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://api.authentication.eu10.hana.ondemand.com
OAuth2TokenServiceURL=https://myaccount.authentication.eu10.hana.ondemand.com/oauth/token
User=sb-full-access!a76125
Password=************
xsuaa.origin=sap.custom
```

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Advanced UAA* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the intermediate Identity Provisioning representation to the SAP BTP XS Advanced UAA target attributes.
   - **User offboarding** – If a user has been deleted from the source system, this change is recognized and the user is deleted in the SAP BTP XS Advanced UAA target system too.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP XS Advanced UAA system. For more information, see Manage Transformations [page 2439] and the API documentation.

   - User Management (System for Cross-domain Identity Management (SCIM))- SCIM groups - role collections
   - User Management (System for Cross-domain Identity Management (SCIM)) - SCIM users - shadow users

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "isValidEmail($.emails[0].value) &&
(('%xsuaa.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%xsuaa.group.prefix%.*/)] empty false))",
    "mappings": [
      {
        "constant": "xsuaa-dummy-value",
        "targetPath": "$.id",
        "scope": "createEntity"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
```

```
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath":"$.name.givenName",
        "targetPath":"$.name.givenName",
        "optional":true
      },
      {
        "sourcePath":"$.name.familyName",
        "targetPath":"$.name.familyName",
        "optional":true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "defaultValue": true,
        "optional": true
      },
      {
        "scope": "createEntity",
        "constant": true,
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.verified",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "scope": "createEntity",
        "constant": true,
        "targetPath": "$.verified"
      },
      {
        "constant": "%xsuaa.origin%",
        "targetPath": "$.origin"
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "condition": "$.emails[?(@.primary == true)].value == []",
        "targetPath": "$.emails[0].primary",
        "constant": true
      },
      {
        "constant": "urn:scim:schemas:core:1.0",
        "targetPath": "$.schemas[0]"
      }
    ]
```

```
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
xsuaa.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
xsuaa.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "mappings": [
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "targetVariable": "entityIdTargetSystem",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
xsuaa.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%xsuaa.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.description",
        "targetPath": "$.description",
        "optional": true
      },
      {
        "constant": "urn:scim:schemas:core:1.0",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      },
      {
        "constant": "USER",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.members[*].type",
        "optional": true
      }
    ]
  }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP BTP Integration Scenario

1.6.2.15.1 Configure Single and Multiple Origins

Configure and provision users with single or multiple origins in SAP BTP XS Advanced UAA (Cloud Foundry) target system.

Context

An origin tells you which is the identity provider of a user in SAP BTP XS Advanced UAA (Cloud Foundry). It is defined in the trust configuration in the SAP BTP cockpit under *Security* > *Trust Configuration* > *Origin Key*.

The origin itself is not a concept of Identity Provisioning. The role of the service is to ensure that you can read and provision users with their identity providers. Once you find the identity provider in the Origin Key, you need to set it in the `xsuaa.origin` property. You can configure it in source, target and proxy SAP BTP XS Advanced UAA (Cloud Foundry) systems. Both single and multiple values are supported. The value is a string that usually specifies the name of the identity provider or its location.

For example: `xsuaa.origin=`*ldap* and `xsuaa.origin=` *ldap;myaccount-xsuaa.accounts.ondemand.com*, where the ";" (semicolon) is the only supported delimiter.

Provisioning Users with Single Origin

You want to provision a user from a given source system to SAP BTP XS Advanced UAA (Cloud Foundry) target system where a single origin is configured.

1. On the *Properties* tab of the target system, enter the value for the `xsuaa.origin` property, for example: *idp1*.
2. (Optional) Ensure the property resolving the uniqueness of the attributes is configured. By default, it is set to: `xsuaa.user.unique.attribute=`*userName*.
3. Run a provisioning job from the source system.

As a result, users are created with a single origin in the target system.

Provisioning Users with Multiple Origins

You want to provision a user from a given source system to SAP BTP XS Advanced UAA (Cloud Foundry) target system where multiple origins are configured.

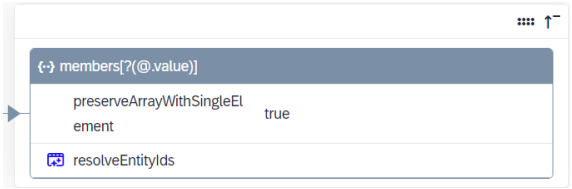
1. On the *Properties* tab of the target system, enter multiple values for the `xsuaa.origin` property, for example: *idp1;idp2*.
2. Ensure the property resolving the uniqueness of the attributes is configured and contains the *origin* value. For example, set it to: `xsuaa.user.unique.attribute`=*userName,origin*.
3. On the *Transformations* tab, update the SAP BTP XS Advanced UAA (Cloud Foundry) target system transformation by adding "[]" (square brackets) to ensure that the following constant supports multiple values:

JSON Text Editor	Graphical Editor
Code Syntax `{ "constant":"%xsuaa.origin%[]", "targetPath":"$.origin" },`	

> ### Note
>
> In case you use the `resolveEntityIds` function in your SAP BTP XS Advanced UAA (Cloud Foundry) target system transformation to resolve the value of one group member in the `sourcePath` to exactly one group member in the `targetPath`, this won't work with multiple origin values. You need to change the `targetPath` in the transformation so that the value of one group member is resolved to multiple group members. See the example below.

JSON Text Editor	Graphical Editor
Current mapping: Code Syntax `{ "sourcePath":"$.members[0].value", "preserveArrayWithSingleElement":true, "optional":true, "targetPath":"$.members[0].value", "functions":[ { "function":"resolveEntityIds" } ] },`	Current mapping:

JSON Text Editor	Graphical Editor

Expected mapping:
Code Syntax
`{`
`"sourcePath":"$.members[0].value",`
`"preserveArrayWithSingleElement":true,`
`"optional":true,`
`"targetPath":"$.members[?(@.value)]",`
`"functions":[`
`{`
`"function":"resolveEntityIds"`
`}`
`]`
`},`
	Expected mapping:
	 


4. Run a provisioning job.

As a result, two entries for one and the same user are created. Both entries contain the same user attributes (for example, username and email address) and differ only in their origins. The job logs show that one user is read and two users are created.

If the provisioned user is assigned to a group, this group will have two user entries assigned as group members which differ only in their origins.

> **Note**
>
> Multiple origins are not supported in provisioning scenarios between SAP BTP XS Advanced UAA (Cloud Foundry) source system and SAP BTP XS Advanced UAA (Cloud Foundry) target system.

Change From Single to Multiple Origins

You have provisioned users to SAP BTP XS Advanced UAA (Cloud Foundry) with a single origin and now you want to provision them with multiple ones.

Follow the steps in the *Provisioning Users with Multiple Origins* above. Before you run the provisioning job, you must reset the target system. For more information, see Reset Identity Provisioning System [page 2485]

1.6.2.16 SAP Build Work Zone, advanced edition

Follow this procedure to set up SAP Build Work Zone, advanced edition as a target system.

Prerequisites

You have OAuth credentials for SAP Build Work Zone, advanced edition. To learn how, see SAP Build Work Zone, advanced edition: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a target SAP Build Work Zone, advanced edition system to provision users and groups.

These target systems consume SCIM 2.0 API provided by SAP Build Work Zone, advanced edition.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Build Work Zone, advanced edition* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Build Work Zone, advanced edition and configure the authentication method (basic or OAuth certificate-based).

   > ### Note
   >
   > We recommend that you use OAuth certificate-based authentication in the regions where it is supported by SAP Build Work Zone, advanced edition. This authentication method is supported for subaccounts created on the recommended data centers for new customers according to the SAP Build Work Zone, advanced edition documentation.

   a. In your newly added SAP Build Work Zone, advanced edition target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in the SAP Build Work Zone, advanced edition Admin Console and are relevant for certificate-based authentication only.

   b. Login to the SAP Build Work Zone, advanced edition Admin Console and execute substep *2. f. iii. Use X.509 Certificate-Based Authentication* from *Step 3: Configure the Identity Authentication service and the Identity Provisioning service* in Option 1: Create a new tenant .

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Build Work Zone, advanced edition system, in format: **`https://<account><sap_wz_domain>.workzone.ondemand.com`** For example: *https://mytenant.mydomain123.workzone.ondemand.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the OAuth client key, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Enter the OAuth client secret, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Build Work Zone, advanced edition instance, based on the configured authentication method: • *BasicAuthentication* - **`https://<account><sap_wz_domain>.workzone.ondemand.com/api/v1/auth/token`** For example: *https://myaccountmydomain123.workzone.ondemand.com/api/v1/auth/token* • *ClientCertificateAuthentication* - **`https://<company_uuid>.api-<region_host>.dws.workzone.ondemand.com/api/v2/auth/token`** **Note** The `api-` prefix before `<region_host>` is necessary for using *ClientCertificateAuthentication* authentication. For example: *https://mycompanyuuid123.api-eu-20.dws.workzone.ondemand.com/api/v2/auth/token*
`client_id`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth Client id used for access token retrieval.
Optional Properties	
(Optional) `workzone.content.type`	This property makes the SAP Build Work Zone, advanced edition target system to send the specified value for the *Content-Type* HTTP header. Example: **application/json** Default value (when not specified): *application/scim+json*
(Optional) `workzone.support.patch.operation`	This is a default property – it appears during system creation. Its default value is *true*. That means, when the Identity Provisioning identifies a changed entity in the source system, it will execute the updates as PATCH requests instead of PUT. That means, only the changes will be written in SAP Build Work Zone, advanced edition, instead of provisioning the whole entity data.

Property Name	Description & Value
(Optional) `workzone.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the SAP Build Work Zone, advanced edition target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). Default value (when not specified): *userName* To learn more, see: List of Properties
(Optional) `workzone.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists on the SAP Build Work Zone, advanced edition target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for this property. Default value (when not specified): *displayName* To learn more, see: List of Properties
(Optional) `workzone.include.if.match.wildcard.header`	This property makes the SAP Build Work Zone, advanced edition target system to send the *If-Match* HTTP header with a value of "*" for every request to SAP Build Work Zone, advanced edition. This header could be used for entity versioning. Default value (when not specified): *false*
(Optional) `ips.failed.request.retry.attempts`	Predefined value: *2*
(Optional) `ips.failed.request.retry.attempts.interval`	Predefined value: *30*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Build Work Zone, advanced edition* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Build Work Zone, advanced edition. For more information, see:

   Manage Transformations [page 2439]

   SAP Build Work Zone SCIM API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "('%workzone.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%workzone.group.prefix%.*/)] empty false)",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",

                ]
            }
        ]
    }
}
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.17 SAP Build Work Zone, standard edition

Follow this procedure to set up SAP Build Work Zone, standard edition as a target system.

Prerequisites

You have created an instance and generated a service key for the standard service plan of SAP Build Work Zone, standard edition. For more information, see: Initial Setup.

The service key contains the API URL and the OAuth credentials (`clientid` and `clientsecret`) under the `uaa` property.

Context

The SAP Build Work Zone, standard edition simplifies access to SAP, custom-built, and third party applications and extensions (both on the cloud and on premise) by establishing a central launchpad.

You can use the Identity Provisioning UI to configure SAP Build Work Zone, standard edition as a target system for provisioning users, groups and users' group assignments from various source systems.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Build Work Zone, standard edition* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP Build Work Zone, standard edition API URL from the service key of your SAP Build Work Zone, standard edition instance under `endpoints [portal-service]`. It follows the pattern: `https://portal-service.cfapps.sap.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, from the service key of your SAP Build Work Zone, standard edition instance under `uaa.clientid`.
`Password`	(Credential) Enter the OAuth Client Secret, from the service key of your SAP Build Work Zone, standard edition instance under `uaa.clientsecret`.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL from the service key of your SAP Build Work Zone, standard edition instance. It follows the pattern: `<uaa.url>/oauth/token`. For example: `https://ips-cflp-woaealle.authentication.sap.hana.ondemand.com/oauth/token`
`cflp.providerId`	Enter a valid providerID value. The provider ID is specified in the Channel Manager of the SAP Build Work Zone, standard edition when defining a new content provider. For more information about configuring the content provider to use the Identity Provisioning service, see: Manage Content Providers (Cloud), Manage Content Providers (On Premise). **Note** All users and groups are provisioned to the target SAP Build Work Zone, standard edition system with the providerID defined for this target system. If you want to use different providerIDs, you need to create separate target systems for every providerID.

Property Name	Value
`cflp.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. SAP Build Work Zone, standard edition supports the following unique attributes which are automatically filled in when the target system is added in the service UI: **`emails[0].value, ['urn:ietf:params:scim:schemas:extension:2.0:mapping'] ['providerId'],externalId`** **Note** SAP Build Work Zone, standard edition, only supports **`externalId`** of type UUID. • If the user has an **`externalId`**, the conflict is resolved by **`externalId`** and **`providerId`**. • If the user doesn't have an **`externalId`**, the conflict is resolved by **`email`** and **`providerId`**. The general rule is that to resolve the conflict, there should be an existing user who matches both unique attributes. However, when resolving conflicts, Identity Provisioning decides whether to update an existing user or create a new one based on several criteria: whether the user was created by the Identity Provisioning service, if any of the provisioning systems (source or target) have been reset, and last but not least, the unique combination of user attributes. For more information, see **Step 4**. → Recommendation We recommend that you do not modify the value of the `cflp.user.unique.attribute` property. Otherwise, user creation fails.

Property Name	Value
`cflp.group.unique.attribute`	If Identity Provisioning tries to provision a group that already exists in the target system (a conflicting group), this property defines the unique attributes by which the existing group will be searched and resolved. SAP Build Work Zone, standard edition supports a pair of unique attributes which is automatically filled in when the target system is added in the service UI: **`externalId, ['urn:ietf:params:scim:schemas:extension:2.0:mapping']['providerId']`** For the conflict to be resolved, an existing group matching both unique attributes should be found. In this case, Identity Provisioning updates the group. This means, the conflicting group overwrites the existing one. If the group matches only one of the unique attributes, the conflict is not resolved, and the group creation fails. → Recommendation We recommend that you do not modify the value of the `cflp.group.unique.attribute` property. Otherwise, the group creation fails.
`cflp.support.bulk.operation`	This property enables bulk operations for users and groups. When the property is enabled (set to *true*), the following operations can be executed by Identity Provisioning service in a single request: • Create or delete multiple users • Create, update, or delete multiple groups When the property is disabled (set to *false*), the following operations can be executed by Identity Provisioning service for a single entity at a time: • Create or delete a user • Create, update, or delete a group **Possible values:** • *true* • *false* Default value: *false*

Property Name	Value
`cflp.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of operations to be provisioned per request. **Possible values:** Default value: *20* Maximum value: *100* If you enter a number larger than 100, the service will replace it with the default value (20).
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map user and group attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Build Work Zone, standard edition* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Build Work Zone, standard edition entity.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Build Work Zone, standard edition system. For more information, see: Manage Transformations [page 2439].

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   ### User Update and Uniqueness

   The write transformation of SAP Build Work Zone, standard edition supports three user unique attributes: *externalId*, *email* and *providerId*. Only providerId is mandatory in combination with at least one of the other attributes. Based on the combinations of these attributes, there can be distinguished three types of users:

   - User 1 - with *email* and *providerId*, but no *externalId*

- User 2 - with *externalId* and *providerId*, but no *email*
- User 3 - with all three attributes: *externalId*, *email* and *providerId*

The uniqueness of the user is ensured by the combination of two unique attributes: the *providerId* and *externalId* or the *providerId* and the *email*.

Updating an existing user in the target system depends on how the user is identified there (its combination of unique attributes) and whether Identity Provisioning is aware of this user:

- The existing user was created by a provisioning job (that is, the service is aware of this user).
  If the following attributes are changed in the source system: the *email* of user 1, the *externalId* of user 2, or the *email* or *externalId* of user 3, after running a new job, Identity Provisioning will update the existing user.
- The existing user was not created by a provisioning job or was created by one but afterwards the source and the target systems have been reset (that is, the service is not aware of this user).
  If the following attributes are changed in the source system, expect the subsequent results after running a new job:
  - Changing the *email* of user 1 will result in creating a new user in the target system, because the user won't match the combination of two unique attributes: *email* and *providerId*.
  - Changing the *externalId* of user 2 will result in creating a new user in the target, because the user won't match the combination of two unique attributes: *externalId* and *providerId*.
  - Changing the *email* or the *externalId* of user 3 will result in updating the user in the target system, because the user will still match a combination of two unique attributes. However, changing both, the *email* and the *externalId*, of user 3 will result in creating a new user in the target system, because the user will match only one unique attribute - the *providerId*.

Default transformation:

            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

Configure Integration with the Identity Provisioning Service

1.6.2.18 SAP Business Network

Follow this procedure to set up SAP Business Network as a target system.

Context

> **Note**
>
> Currently, the SAP Business Network connector cannot be used by customers due to API access constraints. SAP is working on resolving these constraints to make the connector fully operational and accessible.

SAP Business Network, formerly known as Ariba Network, is a cloud-based offering that makes it possible for buyers and suppliers to collaborate on transactions, strengthen their relationships, and discover new business opportunities.

You can use Identity Provisioning to configure SAP Business Network as a target system where you can provision users and update group members.

> **Note**
>
> Identity Provisioning cannot create and delete groups in SAP Business Network target system. It can only update existing groups by adding or removing group members. Therefore, groups must have been created in SAP Business Network before you run a provisioning job.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Business Network* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the SAP Business Network API URL.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	Enter the OAuth Client Id, created for your SAP Business Network system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Business Network system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.
`bn.api.key`	An API Key represents the unique key that identifies a particular application as a legitimate consumer of an API.
`bn.realm.id`	The realm name is part of the URL you use to access SAP Business Network.
(Optional) `bn.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. The property is not added automatically at system creation. Default value: *userName* If the service finds an existing user by userName, it updates this user with the data of the conflicting one. If the service does not find an existing user by userName, the creation of the conflicting user fails.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Business Network* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Business Network system. For more information, see:

Manage Transformations [page 2439].

To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Business Network entity.

Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "($.emails.length() > 0) && ($.name.givenName EMPTY
false) && ($.name.familyName EMPTY false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",
          "urn:ietf:params:scim:schemas:extension:sap:2.0:User",

"urn:ietf:params:scim:schemas:extension:sap.business.network:2.0:User",
          "urn:com.sap.ariba.framework.scim2.common.types.UserResourceV2"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
        "optional": true
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:sap.business.network:2.0:User']
['userStatus']",
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:sap.business.network:2.0:User']
['userStatus']",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
```

```
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true,
        "defaultValue": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.name.formatted",
        "targetPath": "$.name.formattedName",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificPrefix",
        "targetPath": "$.name.honorificPrefix",
        "optional": true
      },
      {
        "sourcePath": "$.name.honorificSuffix",
        "targetPath": "$.name.honorificSuffix",
        "optional": true
      },
      {
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.emails[0].value"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "condition": "$.addresses[?(@.type == 'work')].country EMPTY
false",
        "sourcePath": "$.addresses[?(@.type == 'work')]",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.addresses[0]"
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.preferredLanguage",
        "targetPath": "$.preferredLanguage",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
```

```
      {
        "sourcePath": "$.timezone",
        "targetPath": "$.timezone",
        "optional": true
      }
    ]
  },
  "group": {
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": ["urn:ietf:params:scim:schemas:core:2.0:Group"],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName"
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "entityType": "group",
            "type": "resolveEntityIds"
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "entityType": "user",
            "type": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Business Network

1.6.2.19 SAP Central Business Configuration

Follow this procedure to set up SAP Central Business Configuration (in short, CBC) as a target system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the API of SAP Central Business Configuration for creating or updating user and group member information.

Context

Create a CBC target system to provision users and group members to it.

> ⚠ Caution
>
> You can't create or delete groups on CBC. That means:
>
> - On the attempt to create a group on CBC, Identity Provisioning will only add new members or update existing ones. Also, when the service reads a group from a source system, there must be a group with the exact same display name (case sensitive) in the CBC target system. Otherwise, an error will be thrown and the group members will not be updated.
> - On the attempt to delete a group on CBC, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Central Business Configuration* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your CBC system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Specify the technical user for your CBC system.
`Password`	(Credential) Specify the password for your technical user.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://mycbcaccount.authentication.us2.hana.ondemand.com/oauth/token**
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Central Business Configuration* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your CBC system. For more information, see Manage Transformations [page 2439].

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target CBC entity.

   Default transformation:

   Code Syntax

   ```
   {
   ```

```
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
cbc.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
cbc.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schema[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "isAttributeWithMandatoryPrefix(@,
cbc.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%cbc.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    },
    "user": {
    "condition": "('%cbc.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%cbc.group.prefix%.*/)] empty false)",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "constant":
"urn:sap:cloud:scim:schemas:extension:custom:2.0:User",
                "targetPath": "$.schemas[1]"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
```

```
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "targetPath": "$.emails[0].primary",
                "condition": "$.emails[?(@.primary == true)].value == []",
                "constant": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.userType",
                "optional": true,
                "targetPath": "$.userType"
            }
        ]
    }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Central Business Configuration – Collection

1.6.2.20 SAP Commerce Cloud

Follow this procedure to set up SAP Commerce Cloud as a target system.

Prerequisites

- In SAP Commerce Cloud, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Configuring OAuth Client.

Context

SAP Commerce Cloud is a highly flexible and modular platform for delivering modern customer experiences. It provides a standardized, automated, end-to-end solution that allows your projects to release code from repository to cloud.

You can use Identity Provisioning to configure SAP Commerce Cloud as a target system to provision users and groups. These target systems consume SCIM 2.0 API provided by SAP Commerce Cloud. For more information, see Commerce Cloud SCIM Web Services API Documentation.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Commerce Cloud* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Commerce Cloud system. The URL follows the pattern: `https://backoffice.<tenant>. model-t.cc.commerce.ondemand.com` You can find the correct URL in the *Environments* section of SAP Cloud Portal.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Commerce Cloud.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Commerce Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Commerce Cloud instance.

Property Name	Description & Value
(Optional) `cc.user.unique.attribute`	This property defines by which unique attribute(s) an existing user in the target system will be searched and resolved in case Identity Provisioning tries to provision a conflicting user. SAP Commerce Cloud supports the following unique attributes which are automatically filled in during system creation: **`emails[0].value, userName, externalId`**. If the service finds an existing user by at least one of the unique attributes, it updates this user with the data of the conflicting one. If such a user is not found, the update of the conflicting user fails. If more than one users with these unique attributes are found, the update fails.
(Optional) `cc.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In this case, the existing group only needs to be updated. This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is **`displayName`**. If the service finds an existing group by this unique attribute, the group that you try to provision will overwrite the existing one. If such a group is not found, the group that you try to provision will not be created in the target system.
(Optional) `cc.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for target systems: *false*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Commerce Cloud* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   > ### Note
   >
   > Users that are created in SAP Commerce Cloud through the UI, don't have an ID and a username. When synchronizing such users from a source system to SAP Commerce Cloud target system, Identity Provisioning detects that they already exist. To resolve the conflict, the service tries to retrieve them from the target, but as they have no IDs, the users are skipped.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Commerce Cloud system. For more information, see:

   Manage Transformations [page 2439].

   Commerce Cloud SCIM Web Services API Documentation

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   ### Code Syntax

```
{
    "user": {
        "condition": "$.userName EMPTY false && (('%cc.group.prefix%' ===
'null') || ($.groups[?(@.display =~ /%cc.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {

                        "function": "replaceFirstString",
```

```
                        "regex": "%cc.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585].

Related Information

SAP Cloud Identity Services Integration Architecture → cloudscimwebservices extension

1.6.2.21 SAP Concur

Follow this procedure to set up SAP Concur as a target system.

Prerequisites

- You are using User v1 API, Identity v4 API or SCIM v4 API.

  > **Note**
  >
  > The **User v1 API** has been decommissioned. For more information, see Concur User API Decommission.

- Your SAP Concur admin user has obtained a *Company Request Token* and a *Company UUID* from the SAP Concur Company Request Token self-service tool.
  For more information, see SAP Concur Company Request Token.

Context

Companies that use SAP Concur for managing and controlling travel expenses, invoices and other can use Identity Provisioning service to automate the identity and access management for the SAP Concur solution.

This service allows you to provision identity data from your existing corporate identity stores, such as SAP AS ABAP or Microsoft Active Directory, or provision employee user data from different SAP cloud user stores, such as SAP SuccessFactors or SAP Cloud Identity Service – Identity Authentication.

The SAP Concur integration with Identity Provisioning is supported with Standard and Professional editions.

SAP Concur provides different APIs for integration with Identity Provisioning, resulting in different connector versions. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `concur.api.version` property controls which API you use.

- When the value is set to **3**, the SCIM v4 API is used. It supports the provisioning of users and group assignments. However, group assignments are ignored by the default write transformations and are provisioned only if the `ignore` parameter is set to `false`.

  > **Note**
  >
  > Identity Provisioning cannot create and delete groups in SAP Concur target system. It can only create, update and delete user assignments of a group. Therefore, groups must have been created in SAP Concur system before you run a provisioning job.

  By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced. The default version is the latest released connector version at the time the system is created.
- When the value is set to **2**, the Identity v4 API is used. This applies to systems created between December 8, 2021, and December 1, 2025. Identity v4 API supports provisioning of users with the `userUUID` attribute, which is generated by Identity Authentication at user creation.
- When the value is set to **1**, or the property is not defined, the User v1 API is used. This applies to systems created before versioning was introduced on December 8, 2021. Version 1 is deprecated.

For more information on how to update to the connector version you need, see: Update Connector Version [page 2424].

To create SAP Concur as a target system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Concur* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Connector Version 1 Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value

`URL`	For EU2 data center, enter:
	`eu2.concursolutions.com`
	For US2 data center, enter:
	`www.concursolutions.com`

`ProxyType`	Enter: **`Internet`**
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *1* to use User v1 API.
`Authentication`	Enter: *BasicAuthentication*
`User`	Deprecated property. Do not use.
`Password`	Deprecated property. Do not use.
`X-ConsumerKey`	Deprecated property. Do not use.
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`

Property Name	Description & Value
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Connector Version 2 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *2* to use the Identity v4 API. This was the default value for systems created between December 8, 2021, and December 1, 2025.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.

Property Name	Description & Value
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com
`concur.user.unique.attribute`	This property defines by which unique attribute(s) an existing user in the target system will be searched and resolved in case Identity Provisioning tries to provision a conflicting user. This property appears by default when the system is created. Its value is set to *userName*. Other possible values: • userName • Another unique attribute that supports filtering.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Connector Version 3 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*

Property Name	Description & Value
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *3* to use the SCIM v4 API. By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.

Property Name	Description & Value
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com
`concur.user.unique.attribute`	This property defines by which unique attribute(s) an existing user in the target system will be searched and resolved in case Identity Provisioning tries to provision a conflicting user. Possible values: • userName (Default value) • externalId • urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:employeeNumber **Note** In SAP Concur, *userName*, *externalId*, and *employeeNumber* are unique user attributes, but only *userName* is required. To ensure proper conflict resolution, *externalId* and *employeeNumber* must also be present in the source.
`concur.group.unique.attribute`	This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is *displayName*. If the service finds an existing group by this unique attribute, the group that you try to provision will overwrite the existing one. If such a group is not found, the group that you try to provision will not be created in the target system.

Property Name	Description & Value
`concur.group.prefix`	This property distinguishes SAP Concur groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`Concur_`** You can use the example value or provide your own. When **set in the target system**, only groups containing the **`Concur_`** prefix in their display name will be provisioned to SAP Concur. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Concur. For more information, see List of Properties.
(Optional)`concur.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for target systems: *false*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Concur* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Concur. For more information, see:

Manage Transformations [page 2439]

SAP Business Accelerator Hub: Concur (Users)

User v1 API: User v1

Identity v4 API: Identity v4

SCIM v4 API: SCIM v4 API

Default transformation when using User v1 API (connector version 1):

            },
            {
                "constant": "DEFAULT",
                "targetPath": "$.LedgerCode"
            },
            {
                "constant": "en_US",
                "targetPath": "$.LocaleName"
            }
        ]
    }
}
```

- **Mapping logic** – When the SAP Concur system is configured as a target, the default transformation logic offered by the Identity Provisioning service contains the minimum of required properties for the successful provisioning of the users. You can change the default transformation mapping rules to reflect your current setup of entities in the source system. Before you start extending the default transformation, you have to get familiar with the requirements of the SAP Concur API to avoid inconsistencies. For more information, see User v1.
- **User off-boarding** – Identity Provisioning service handles the end-to-end lifecycle of the users, including their off-boarding. For some source systems, the deletion of a user or inactive user status is the final step of this lifecycle process. The SAP Concur solution, however, does not allow user accounts to be deleted. The offboarding of SAP Concur user accounts is always performed by setting them as disabled. When a user is deleted or set with status **inactive** in a system configured as a source for

user data provisioning to SAP Concur, the user account in SAP Concur will be disabled (the attribute `"targetPath": "$.Active"` gets a value "**N**").

⚠ Caution

The User v1 API requires an initial password setup for all newly provisioned user accounts. The default transformation offers a statement with an empty string as a value for the password configuration. However, it is ignored in order to prevent from a default setup of a wrong initial password for your systems. While the password statement is ignored, the provisioning will not be working. To enable the provisioning to SAP Concur, you need to perform the following operations:

1. Enable the password statement. To do this, either delete **"ignore": true,** or set it as **"ignore": false**.
2. Set a proper statement for the password attribute value (**"targetPath": "$.Password"**).

(Optional) You can leave the default empty string, or you can use the **randomPassword** function to calculate a random value for the initial password of the newly created SAP Concur accounts. If you choose one of these two options and if you are not using single sign-on solution for SAP Concur, you have to also arrange a password reset support process in your company. This will securely offer an initial password to your corporate users for their newly created SAP Concur accounts. For more information, see Transformation Expressions [page 391] → **Transformation Functions**.

The Identity Provisioning does not provide group resource mapping in the SAP Concur write transformation. Although you cannot provision groups to SAP Concur, you can group the users into organizational units by enhancing your target transformation as follows:

{·} Sample Code

```
...

    {
            "constant": "<provided by SAP Concur>",
            "targetPath": "$.LedgerCode"
        },
        {
            "constant": "<obtain from SAP Concur API>",
            "targetPath": "$.Custom21"
        },
        {
            "constant": "<obtain from SAP Concur API>",
            "targetPath": "$.OrgUnit1"
        },
        {
            "constant": "<obtain from SAP Concur API>",
            "targetPath": "$.OrgUnit2"
        }
    {
            "constant": "DEFAULT" or "<obtain from SAP Concur API>",
            "targetPath": "$.LedgerKey"
        },
```

Default transformation when using Identity v4 API (connector version 2):

{·} Code Syntax

```
{
```

```

        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
        "optional": true,
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['displayName']",
        "optional": true,
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['displayName']"
      }
    ]
  }
}
```

Note

The default transformation for Concur connector version 2 (based on Identity v4 API) provides a mapping that generates the Concur User Login_ID based on the username from the source (Login Name in SAP Cloud Identity Services) and the domain configured as the `concur.company.domain` property.

In case you want to do the following:

- Provision users with usernames that are already in email format
- Use the user email address as SAP Concur Login_ID
- Use other attribute with value in email format as SAP Concur Login_ID

you have to update this mapping and remove the function that appends the domain part. For example:

Default

Code Syntax

```
{
        "sourcePath":
"$.userName",
        "targetPath":
"$.userName",
        "functions": [
          {
            "type":
"concatString",
            "suffix":
"@%concur.company.domain%"
          }
        ]
      },
```

Changed

Code Syntax

```
{
   "condition":"$.emails[?
(@.primary== true)] empty
false",
   "sourcePath":"$.emails[?
(@.primary== true)].value",
   "targetPath":"$.userName",
   "optional":true
},
{
   "condition":"$.emails[?
(@.primary== true)] empty true",

"sourcePath":"$.emails[0].value"
,
   "targetPath":"$.userName",
   "optional":true
},
```

In addition, make sure that this mapping is aligned with the configuration of Name ID attribute in Identity Authentication, as described in Appendix – SAP Cloud Identity Services - Identity Authentication Service (SAP IAS) Setup.

Default transformation when using SCIM v4 API (connector version 3):

Code Syntax

```
{
  "user": {
    "condition": "('%concur.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%concur.group.prefix%.*/)] empty false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
```

```
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",
          "urn:ietf:params:scim:schemas:extension:sap:2.0:User",
          "urn:ietf:params:scim:schemas:extension:enterprise:2.0:User"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "functions": [
          {
            "type": "concatString",
            "suffix": "@%concur.company.domain%"
          }
        ]
      },
      {
        "sourcePath": "$.name",
        "targetPath": "$.name"
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName"
      },
      {
        "condition": "$.name.academicTitle NIN ['Dr.', 'Doctor',
'Prof.','Professor', 'Prof. Dr.', 'Professor Doctor', 'B.A.', 'Bachelor
of Arts', 'MBA', 'Master of Business Administration', 'Ph.D', 'Doctor of
Philosophy']",
        "type": "remove",
        "targetPath": "$.name.academicTitle"
      },
      {
        "sourcePath": "$.addresses[?(@.type NIN ['work', 'home', 'other',
'billing', 'bank', 'shipping'])]",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.addresses",
        "functions": [
          {
            "condition": "(@.country empty false)",
            "type": "convertCountryCode",
            "outputFormat": "alpha2",
            "inputAttributes": [
              "country"
            ],
            "outputAttribute": "country"
          }
        ]
      },
      {
        "targetPath": "$.addresses[*].type",
        "type": "remove"
      },
      {
        "sourcePath": "$.addresses[?(@.type IN ['work', 'home', 'other',

        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
concur.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%concur.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
```

```
      }
    ]
  }
}
```

In SAP Concur connector version 3, *phoneNumbers* and *emails* require a type (such as *work*, *home*, mobile). One phone number and one email are allowed per type, except for *mobile* phone numbers, where multiple entries are permitted. If multiple mobile phone numbers are present, at least one must be primary. When a phone number has no type, Identity Provisioning sets it to *mobile*. When an email has no type, the service sets it to *work*.

A user may have multiple phone numbers, emails and addresses in a given source system. By using the *elementAt* function, only the first element in the array will be retrieved. This function can be applied to phone numbers, emails, or addresses:

Code Syntax

```
{
   "condition":"$.phoneNumbers[?(@.type == 'work')] empty false",
   "sourcePath":"$.phoneNumbers[?(@.type == 'work')]",
   "optional":true,
   "preserveArrayWithSingleElement":true,
   "targetPath":"$.phoneNumbers[0]",
   "functions":[
      {
         "function":"elementAt",
         "index":0
      }
   ]
}
```

The *address* attribute does not require a type. If a type is provided, only one address per type is allowed.

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.22 SAP CPQ

Follow this procedure to set up SAP CPQ (Configure, Price, and Quote) as a target system.

Prerequisites

- You have created a technical user with administrator permissions that will be used to call the API of SAP CPQ for creating and updating user and group information.
- Make sure all users that need to be read from the source system have an organization unit name. This unit name must correspond to an existing company system ID in SAP CPQ. The *organization unit* and the *company system ID* must be exactly the same. Users with empty (missing) organization units will not be provisioned, as well as users whose organization units don't match any of the SAP CPQ company system IDs for the relevant tenant.
- In order for a created user to be active in SAP CPQ, it should be assigned to an SAP CPQ target group, whose ID ends with suffix *–USERTYPE*. To learn more, see SAP CPQ: SCIM API → section **Mappings between SCIM API and SAP CPQ** → `groups`.

Context

SAP CPQ is a highly configurable system designated to help sales representatives to configure products, apply pricing and generate quotes. SAP CPQ is part of the SAP Sales Cloud portfolio.

Create an SAP CPQ target system to provision users and groups to it.

> ⚠ Caution
>
> You can't create or delete groups on SAP CPQ. That means:
>
> - On the attempt to create a group on SAP CPQ, Identity Provisioning will only add new members or update existing ones. Also, if you read a group from a source system, there must be a group with the exact same display name (case sensitive) in the SAP CPQ target system. Otherwise, an error will be thrown and the group members will not be updated.
> - On the attempt to delete a group on SAP CPQ, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP CPQ* as a target system. For more information, see Add New Systems [page 2415].

3. Set up the communication between Identity Provisioning and SAP CPQ and configure the authentication method (basic or OAuth certificate-based).

> **Note**
>
> We recommend that you use OAuth certificate-based authentication.

   a. In your newly added SAP CPQ target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip this step if you use basic authentication. The next steps are relevant for OAuth certificate-based authentication only. For more information, see Configure OAuth Certificate Authentication [page 2456].

   b. Convert your certificate file from `.crt` to `.cer`.

   c. Login to SAP CPQ and navigate to *Security* > *Certificate Management* > *User Certificates* > *New Certificate* and upload the certificate to the technical user of SAP CPQ.

      Make sure the *Enable User Certificates* option is turned on. Additionally, the technical user must be set to *Active*.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`ips.delete.existedbefore.entities`	Enter: *true* SAP CPQ API does not allow creation and deletion of groups. Thus, if a previously read group is later deleted from the source system, this property will delete the relevant members from SAP CPQ (not the group itself).
`ips.delete.threshold.groups`	(Optional) Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
`ips.delete.threshold.users`	(Optional) Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Value
`OAuth2TokenServiceURL`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth 2.0 Token Service URL. For example: `https://<cpq_url>/oauth2/token`
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Specify the password for your technical user.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the URL to the API of your SAP CPQ system. It is the same as your SAP CPQ tenant URL. It must contain the domain name. For example: **https://sample1234.mycpqdomain.com**
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the Username of your SAP CPQ technical user.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Identity Provisioning offers a default transformation for the *SAP CPQ* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP CPQ entity. You can change the default transformation mapping rules to reflect your current setup of entities in your SAP CPQ. For more information, see:

   Manage Transformations [page 2439]

   SAP CPQ: SCIM API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "isValidEmail($.emails[0].value) &&
(('%cpq.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%cpq.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
```

```
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "constant":
"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
                "targetPath": "$.schemas[1]"
            },
            {
                "sourcePath": "$.externalId",
                "optional": true,
                "targetPath": "$.externalId"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.addresses",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.addresses"
            },
            {
                "sourcePath": "$.phoneNumbers",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.phoneNumbers"
            },
            {
                "scope": "createEntity",
                "constant": [],
                "targetPath": "$.groups"
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['organization']",
                "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['organization']"
            },
            {
                "constant": true,
                "targetPath": "$
['urn:sap:cpq:scim:schemas:extension:custom:2.0:User']['IsSsoUser']"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
```

```
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            }
        ]
    },
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
cpq.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
cpq.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "isAttributeWithMandatoryPrefix(@,
cpq.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%cpq.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
Powered by Gitiles
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.23 SAP Data Custodian

Follow this procedure to set up SAP Data Custodian as a target system.

Prerequisites

> ⚠ Restriction
>
> This system is available for all standalone tenants and bundle tenants running on SAP Cloud Identity Services infrastructure. Bundle tenants running on Neo environment can use it only through **SAP Identity Access Governance** bundle option.

- You have created an SAP Data Custodian tenant.
- You have created a user within your tenant with the required roles for your scenario.
- You have added your user to SAP Identity Service Management (SAP ISM).

Context

SAP Data Custodian is a robust Software as a Service (SaaS) solution that protects sensitive data stored in public, private, hybrid, and multicloud environments. This solution integrates with partnered public hyperscalers, SAP applications, and SAP managed clouds.

After fulfilling the prerequisites, follow the procedure below to create a target SAP Data Custodian system to provision users and groups.

These target systems consume SCIM 2.0 API provided by SAP Data Custodian.

SCIM API 2.0 does not support managing of group assignments via the SCIM user resource. The "groups" attribute of the user is read-only. This means that the user group assignments should be managed via the SCIM group resources using the "members" attribute (as it is defined by the SCIM standard).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Data Custodian* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Data Custodian and configure the authentication method (basic or certificate-based).

   > ⓘ Note
   >
   > We recommend that you use certificate-based authentication.

a. In your newly added SAP Data Custodian source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

   Skip this step if you use basic authentication. The next steps are performed in SAP Data Custodian and are relevant for certificate-based authentication only.

b. Login to SAP Data Custodian tenant and create a tenant operations technical user (TOTU), as described in Create a Tenant Operations Technical User in SAP Data Custodian.

c. Upload the outbound certificate that you downloaded in **substep a.** to the TOTU, as described in Register the Outbound Certificate to Your Tenant Operations Technical User.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP Data Custodian SCIM API excluding the path information. `https://<SCIM_API_URL>` For more information, see Identity Provisioning.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* Enter the OAuth client key, created for your SAP Data Custodian tenant. For more information, see Basic Authentication Prerequisites.
`Password`	Valid if *BasicAuthentication* (Credential) Enter the OAuth client secret, created for your SAP Data Custodian tenant. For more information, see Certificate Authentication Prerequisites.
`OAuth2TokenServiceURL`	Specify the URL of the access token provider service for your SAP Data Custodian instance: `https://<SCIM_API_URL>/kms/scim/v1/Oauth2/Token`

Property Name	Description & Value
`dc.group.prefix`	This property distinguishes SAP Data Custodian groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **DC_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **DC_** prefix in their display name will be provisioned to SAP Data Custodian. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Data Custodian.
`dc.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `dc.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName*
`dc.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system via this filter, the creation will fail. **Default behavior**: The property is missing during system creation. Its default value is *userName*. This means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. **Possible values:** Default value: *userName*

Property Name	Description & Value
`dc.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. This means, for example, that if a user attribute is modified, only this change will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Data Custodian* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Jam Collaboration. For more information, see:

   Manage Transformations [page 2439]

   SAP Data Custodian SCIM 2.0 API

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "isValidEmail($.emails[0].value) &&
(('%dc.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%dc.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:User",

"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:User",
                    "urn:sap:cloud:scim:schemas:extension:custom:2.0:User"
                ],
                "targetPath": "$.schemas"
            },
            {
                "condition": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid'] EMPTY
false",
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "targetPath": "$.externalId"
            },
            {
                "condition": "$.externalId EMPTY false",
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId"
            },
            {
                "condition": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['userId'] EMPTY
false",
                "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['userId']",
                "targetPath": "$.externalId"
            },
            {
                "condition": "$.emails[?(@.primary == true)].value == []",
```

```
                "sourcePath": "$.emails[0].value",
                "targetPath": "$.userName"
            },
            {
                "condition": "$.emails[?(@.primary == true)].value != []",
                "sourcePath": "$.emails[?(@.primary == true)].value",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.userName",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "optional": true,
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.name.formatted",
                "optional": true,
                "targetPath": "$.name.formatted"
            },
            {
                "sourcePath": "$.name.honorificPrefix",
                "optional": true,
                "targetPath": "$.name.honorificPrefix"
            },
            {
                "sourcePath": "$.name.honorificSuffix",
                "optional": true,
                "targetPath": "$.name.honorificSuffix"
            },
            {
                "sourcePath": "$.name.middleName",
                "optional": true,
                "targetPath": "$.name.middleName"
            },
            {
                "sourcePath": "$.active",
                "optional": true,
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            }
        ]
    },
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
dc.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
dc.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
```

```
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "isAttributeWithMandatoryPrefix(@,
dc.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%dc.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ### Note
>
> When Identity Authentication is configured as a source system, the default transformation logic:
>
> - Provisions only groups and user group assignments if they are part of the following predefined group list:
>   - *SAP_Data_Custodian_Auditor*
>   - *SAP_Data_Custodian_Service_Admin*
>   - *SAP_Data_Custodian_Key_Admin*
>   - *SAP_Data_Custodian_Key_User*
> - Skips some of the attributes from the identity records.
> - Sets primary email for `userName` of the user.
>
> This way, the transformation logic ensures that the identity data, sent to the Identity Provisioning SCIM REST API, is consistent.

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP Data Custodian

1.6.2.24 SAP Datasphere

Follow this procedure to set up SAP Datasphere as a target system.

Prerequisites

- In SAP Datasphere, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- In SAP Datasphere, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Create OAuth2.0 Clients to Authenticate Against SAP Datasphere

Context

SAP Datasphere is a solution that harmonizes data management, analytics, and intelligent planning, including capabilities of SAP Data Intelligence Cloud and SAP Analytics Cloud. The solution enables SAP customers to consolidate their SAP data and analytics needs into a single SAP solution.

You can use Identity Provisioning to configure SAP Datasphere as a target system where you can provision users. The target system consumes SCIM 2.0 API provided by SAP Datasphere.

> **Note**
>
> SAP Datasphere does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Datasphere* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Datasphere system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Datasphere.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Datasphere.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Datasphere instance. This token URL is listed in the *Trusted Identity Providers* section of the *App Integration* page. For more information, see Create OAuth2.0 Clients to Authenticate Against SAP Datasphere
`ds.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. This property is automatically added to the system, with default value: **enabled**

Property Name	Description & Value
`ds.user.unique.attribute`	This property appears by default when the system is created, and its value is set to *userName*. It defines by which unique attribute(s) an existing user to be resolved in the event of conflicting users. Other possible values: • **emails[0].value** • **userName,emails[0].value** • **externalId**, or another SCIM attribute, or a conjunction of SCIM attributes **Note** If this property is missing, or you've deleted it, and the service does not find such a *userName*, it will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is unsuccessful too, the creation of the conflicting user fails. For more information, see: List of Properties [page 80]
`ds.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a PATCH request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false*

Property Name	Description & Value
(Optional) `ds.support.bulk.operation`	Set this property to *true* if you want to enable SCIM bulk operations for provisioning users. That means, the Identity Provisioning service can write, update, and delete a potentially large collection of users in a single request. For more information, see: SCIM Protocol: Bulk Operations and Bulk Operations If not specified, the default value is *false*.
(Optional) `ds.bulk.operations.max.count`	If you have enabled the SCIM bulk operations, you can use this property to set the number of users to be provisioned per request. Default value: **30** **Note** The value must not exceed the number of entities defined by the SAP Datasphere system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Payload Too Large*).
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Datasphere* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Datasphere system. For more information, see: Manage Transformations [page 2439]

   SAP Datasphere SCIM 2.0 API

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "($.emails[0].value EMPTY false) &&
isValidEmail($.emails[0].value) && ($.userName EMPTY false)",
    "mappings": [
```

```
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",

      },
      {
        "sourcePath": "$.emails[0].value",
        "optional": true,

"targetPath": "$['urn:sap:params:scim:schemas:extension:sac:2.0:user-
custom-parameters']['idpUserId']"
      },
      {
        "condition": "$.emails[?(@.primary == true)].value != []",
        "sourcePath": "$.emails[?(@.primary == true)].value",
        "preserveArrayWithSingleElement": false,
        "optional": true,

"targetPath": "$['urn:sap:params:scim:schemas:extension:sac:2.0:user-
custom-parameters']['idpUserId']"
      },
      {

"sourcePath": "$['urn:sap:params:scim:schemas:extension:sac:2.0:user-
custom-parameters']['idpUserId']",
        "optional": true,

"targetPath": "$['urn:sap:params:scim:schemas:extension:sac:2.0:user-
custom-parameters']['idpUserId']"
      },
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
        "optional": true,
        "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
        "functions": [
          {
            "type": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

> **Note**
>
> Updating a user in SAP Datasphere depends on whether user attributes in SAP Datasphere are mapped to SAML attributes in your identity provider. If this is the case, the values of those attributes are populated by the identity provider and cannot be changed by the SAP Datasphere SCIM API or the UI. For more information, see Map SAML Attributes to Users and Create a User.

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

> **Caution**
>
> The **email** attribute is unique for *SAP Datasphere* but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in *SAP Datasphere*.
>
> To learn more, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from SAP Datasphere target, see: Exclude Users from Provisioning to Target Systems

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.25 SAP Document Center

Follow this procedure to set up SAP Document Center as a target system.

Prerequisites

- You have an SAP Business Technology Platform user with administration rights for the tenant.
- You have enabled the SAP Document Center service in the cockpit.

Context

SAP Document Center offers programs (apps) that can be downloaded and run on multiple independent devices. For more information, see SAP Document Center.

It plays the role of a content service for your SAP Business Technology Platform subaccount. To use it as a target system for writing users, follow the procedure below.

Procedure

1. Assign your SAP Business Technology Platform user **admin** rights for SAP Document Center. To do this, open the *SAP Document Center* service tile (in the cockpit), open link *Assign Roles & Set Destinations*, choose *Administrator*, and then – *Assign*.
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *SAP Document Center* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: **HTTP**
`URL`	Enter the URL, generated in the cockpit for your subaccount in the *SAP Document Center* tile. You can take this URL from the *Configure SAP Document Center* link. Remove the last slash after "…**/admin"**.
`ProxyType`	Enter: **Internet**
`Authentication`	Enter: **BasicAuthentication**
`User`	Enter your SAP Business Technology Platform user (with administrator rights).
`Password`	(Credential) Enter the password for your SAP Business Technology Platform user.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Document Center* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Document Center. For more information, see:

   Manage Transformations [page 2439]

   SAP Document Center: REST API

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "$.userName EMPTY false",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.firstName"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.lastName"
            },
            {
                "sourcePath": "$.emails[0].value",
                "optional": true,
                "targetPath": "$.email"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.logonId"
            }
        ]
    }
}
```

6. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.26 SAP Enable Now

Follow this procedure to set up SAP Enable Now as a target system.

Prerequisites

- You have created a technical user in SAP Enable Now with the necessary permissions for establishing a connection with Identity Provisioning.

Context

The SAP Enable Now solution is SAP's digital adoption platform. It can help you improve the adoption, productivity, and efficiency of your software by providing in-application help and e-learning content to users.

You can use Identity Provisioning to configure SAP Enable Now as a target system where you can provision users and groups. The target system consumes SCIM 2.0 API provided by SAP Enable Now.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Enable Now* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Enable Now system. It follows the pattern: • `https://<company-name>.enable-now.cloud.sap` • `https://<company-name>.sap-enable-now.cn` (relevant for China)
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the username of the SAP Enable Now technical user.
`Password`	(Credential) Enter the password of the SAP Enable Now technical user.
`en.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. Default value: *userName*
`en.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false*

Property Name	Description & Value
(Optional) `en.group.prefix`	This property distinguishes SAP Enable Now groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **EN_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **EN_** prefix in their display name will be provisioned to SAP Enable Now. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Enable Now.
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Enable Now* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Enable Now system. For more information, see: Manage Transformations [page 2439]

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "($.userName EMPTY false) &&
isValidEmail($.emails[0].value) && (('%en.group.prefix%' === 'null') ||
($.groups[?(@.display =~ /%en.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:User",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:User"
                ],
                "targetPath": "$.schemas"
            },
            {
```

```
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
              "sourcePath": "$.name.givenName",
              "optional": true,
              "targetPath": "$.name.givenName"
            },
            {
              "sourcePath": "$.name.middleName",
              "optional": true,
              "targetPath": "$.name.middleName"
            },
            {
              "sourcePath": "$.name.familyName",
              "optional": true,
              "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "optional": true
            },
            {
                "sourcePath": "$.emails",
                "targetPath": "$.emails",
                "preserveArrayWithSingleElement": true
            }
        ]
    },
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
en.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
en.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "targetPath": "$.id",
                "sourceVariable": "entityIdTargetSystem"
            },
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:Group",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:Group"
                ],
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "isAttributeWithMandatoryPrefix(@,
en.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%en.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
```

```
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
                "optional": true
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

> ⚠ Caution
>
> The **email** attribute is unique for *SAP Enable Now* but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in *SAP Enable Now*.
>
> To learn more, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from SAP Enable Now target, see: Exclude Users from Provisioning to Target Systems

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Enable Now

1.6.2.27 SAP Fieldglass

Follow this procedure to set up a target connector for SAP Fieldglass.

Prerequisites

You have created an API application key and a web service. To do that, follow the steps on page: Create API Application Key or Web Service and Web Services Setup

You will need the values of *Virtual Person Name (Username)* and *License Key* for the configuration of your target system (**step 3** below).

Context

After fulfilling the prerequisites, follow the procedure below to add a target system for SAP Fieldglass to write users to it. This target system consumes SCIM 2.0 API provided by SAP Fieldglass.

> ⓘ Note
>
> The system transformation supports groups but cannot directly create new groups. However, you can map groups from the source system to groups from SAP Fieldglass by display name.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Fieldglass* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify your SAP Fieldglass environment URL. For example: *https://abc123.fgvms.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	Enter your *Virtual Person Name (Username)* – see the **Prerequisites** section above.
`Password`	(Credential) Enter your *License Key* – see the **Prerequisites** section above.
`OAuth2TokenServiceURL`	Enter your OAuth token URL in the following format: `https://<Environment_URL>/api/oauth2/v2.0/token` For example: *https://abc123.fgvms.com/api/oauth2/v2.0/token*
(Optional) `fg.group.prefix`	This property distinguishes SAP Fieldglass groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **FG_** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Fieldglass source system and will be provisioned to the target system with the following name pattern: **FG_<GroupDisplayName>**. This way SAP Fieldglass groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Fieldglass groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **FG_** prefix in their display name will be provisioned to SAP Fieldglass. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Fieldglass.
`fg.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. • If set to *false*, PUT operations are used to update users in the target system. Default value: *false* For more information, see: List of Properties [page 80]

Property Name	Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Fieldglass* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Fieldglass. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Fieldglass

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. If the entity has e-mail addresses, the first entry will be marked as primary.
   - **User off-boarding** – Users can be deleted from the target system. Depending on the implementation, this could be done through a user interface (if such exists) or the SCIM REST API. Users could be deactivated, depending on the SAP Fieldglass system implementation. The SCIM core schema defines an attribute "**active**", whose definition depends on the service provider. For more information, see SCIM: Singular Attributes

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "('%fg.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%fg.group.prefix%.*/)] empty false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "scope": "createEntity",
```

```
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.name.familyName"
      },
      {
        "sourcePath": "$.name.formatted",
        "optional": true,
        "targetPath": "$.name.formatted"
      },
      {
        "sourcePath": "$.name.honorificPrefix",
        "targetPath": "$.name.honorificPrefix",
        "condition": "$.name.honorificPrefix IN ['Mr.', 'Mrs.', 'Ms.',
'Dr.']",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.title",
        "targetPath": "$.title",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.emails[0].value"
      },
      {
        "optional": true,
        "defaultValue": "work",
        "sourcePath": "$.emails[0].type",
        "targetPath": "$.emails[0].type"
      },
      {
        "defaultValue": true,
        "optional": true,
        "sourcePath": "$.emails[0].primary",
        "targetPath": "$.emails[0].primary"
      },
      {
        "sourcePath": "$.timezone",
```

```
        "optional": true,
        "targetPath": "$.timezone"
      },
      {

        "sourcePath": "$.members[*].value",
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      },
      {
        "sourcePath": "$.schemas",
```

```
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.schemas"
      }
    ]
  }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.28 SAP Field Service Management

Follow this procedure to set up SAP Field Service Management as a target system.

Prerequisites

You have OAuth credentials for SAP Field Service Management. For more information, see: Generating Client ID & Secret

Context

SAP Field Service Management is a cloud-based solution that is used to resolve customers issues with end-to-end field service management. For example, it helps customers overcome resource limitations, such as having enough skilled technicians in all locations.

You can use the Identity Provisioning user interface (UI) to configure SAP Field Service Management as a target system where you can provision users and group members. When integrated with Identity Provisioning, the cloud solution supports the following group concept:

- A user is created with a default group assigned. A group is mapped to a company (one of the key organizational units in SAP Field Service Management). When using the Identity Provisioning service API, the group is returned as follows:

  ```
  <GroupName>_<CompanyName>
  ```

- A user can have one group assignment for each company. As in SAP Field Service Management a user can be assigned to multiple companies, this requires a group assignment for each of the companies the user can access. A user cannot be assigned to different groups mapped to one and the same company.

> ⚠ Caution
>
> You cannot create or delete groups in SAP Field Service Management. In this case, you can expect the following behavior:
>
> - If a new group is created in the source system (for example, Identity Authentication) and you run the provisioning job to SAP Field Service Management, the job will fail and no group will be created in the target system.
> - If a group exists both in the source system (for example, Identity Authentication) and the target system - SAP Field Service Management, running a provisioning job will only add new members or update existing ones. In this case, groups in the source and target systems must have the same display name (case sensitive). Otherwise, the job will fail, and no group members will be updated.
> - If a group exists in the target SAP Field Service Management system and you try to delete it, Identity Provisioning will only remove its group members. In this case, the relevant group members must exist in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Field Service Management* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Field Service Management system. It follows the pattern: `https://<cluster>.fsm.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Field Service Management system.

Property Name	Value
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Field Service Management system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://<cluster>.fsm.cloud.sap/api/oauth2/v2/token`
(Optional) `fsm.group.prefix`	This property distinguishes SAP Field Service Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`FSM_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the groups that are read from the SAP Field Service Management source system and will be provisioned to the target system with the following name pattern: **`FSM_<GroupDisplayName>`**. This way SAP Field Service Management groups in the target system will be distinguished from groups provisioned from other applications. If the property is not set, the SAP Field Service Management groups will be read and provisioned to the target system with their actual display names. • When **set in the target system**, only groups containing the **`FSM_`** prefix in their display name will be provisioned to SAP Field Service Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Field Service Management.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Field Service Management* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Field Service Management system. For more information, see:

   Manage Transformations [page 2439].

   Field Service Management - SCIM API

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Field Service Management entity.

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value) && (('%fsm.group.prefix%' === 'null')
|| ($.groups[?(@.display =~ /%fsm.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:User",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:User"
                ],
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name.givenName",
```

```
                "targetPath": "$.name.givenName"
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active"
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
                "optional": true,
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
            }
        ]
    },
    "group": {
        "condition": "(isAttributeWithOptionalPrefix($.displayName,
fsm.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
fsm.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup()))
|| ('%fsm.group.prefix%' === 'null') || ($.displayName =~ /
%fsm.group.prefix%.*/)",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "('%fsm.group.prefix%' !== 'null') &&
(@ =~ /%fsm.group.prefix%.*/)",
                        "function": "replaceFirstString",
                        "regex": "%fsm.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.29 SAP HANA Cloud Database Services

Follow this procedure to set up SAP HANA Cloud Database Services as a target system.

Prerequisites

You have created a technical user for Identity Provisioning in the SAP HANA database with the OPERATOR and ROLE ADMIN system privileges. For more information, see SAP Identity Provisioning Service → *Prerequisites*.

Context

SAP HANA Cloud allows you to consume the SAP HANA database from cloud applications running on SAP Business Technology Platform, as well as from applications running elsewhere using the standard SAP HANA clients. Every instance of SAP HANA Cloud has its own single SAP HANA database.

You can use the Identity Provisioning user interface (UI) to configure SAP HANA Cloud Database Services as a target system where you can provision users and group members, that is, user assignments for a role.

The SAP HANA Cloud Database Services connector supports provisioning of entities to the following two database types:

- SAP HANA Database (HDB)
- SAP HANA Data Lake Relational Engine (HDLRE / IQ Database)

You can define the target database type by setting the `hana.cloud.db.instance.type` property to either `hdb` or `hdlre`.

For more information on the supported database types, see SAP HANA Cloud, SAP HANA Database and SAP HANA Cloud, Data Lake.

> **Note**
>
> In SAP HANA Cloud Database Services, groups correspond to roles.

> ⚠ Caution
>
> Identity Provisioning cannot create or delete roles in SAP HANA Cloud Database Services. It can only create, update, and delete user assignments for a role. Therefore, roles must be created in the SAP HANA Cloud Database Services system before running a provisioning job. Additionally, groups in the source system and roles in the target system must have identical names.

Review the expected behavior in the following scenarios:

- If a new group is created in the source system (for example, Identity Authentication) and you run the provisioning job to SAP HANA Cloud Database Services, the job will fail and no role will be created in the target system.
- If a group in the source system (Identity Authentication) and a role in the target system (SAP HANA Cloud Database Services) exist, when running a provisioning job, the user group assignments from the source will be mapped to the user role assignments in the target, provided that the group and role names are identical. If the names do not match, the job will fail, and no role assignments will be updated. You have the following options to handle these discrepancies: use the `valueMappings` expression to change the group names, as described in Transformation Expressions [page 391], or dynamically assign users to groups in SAP HANA Cloud Database Services, as described in Enabling Group Assignment [page 2445].
- If a role exists in the target SAP HANA Cloud Database Services system and you try to delete it, Identity Provisioning will only remove the existing user assignments for that role.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP HANA Cloud Database Services* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://demo-hc-3-test.authentication.sap.hana.ondemand.com/oauth/token` For more information on how to obtain the value, refer to the create a service binding step in the User Provisioning with Identity Provisioning Service.

Property Name	Value
`hana.cloud.db.instance.type`	Refers to the database type configured or used within SAP HANA Cloud. The value can be set to: • **hdb** - SAP HANA Database • **hdlre** - SAP HANA Data Lake Relational Engine Default value: **hdb**
`hana.cloud.db.instance.id`	Refers to a unique identifier associated with a specific database instance within the SAP HANA Cloud.
`hana.cloud.db.providerName`	Specifies the identity provider (IdP) that users managed through Identity Provisioning will use for authentication. The provider must be configured to support the authentication method specified in `hana.cloud.db.authenticationType`. For more information on how to obtain the value, refer to the create a JWT provider step in the User Provisioning with Identity Provisioning Service.
`hana.cloud.db.authenticationType`	Specifies the method by which users managed through Identity Provisioning authenticate when connecting to the database. The authentication method is set to *JWT* (users authenticate via JWT tokens issued by an identity provider) during system creation.

Property Name	Value
`hana.cloud.db.group.prefix`	(Optional) This property distinguishes SAP HANA Cloud Database Services roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`HANA_Cloud_DB_`** You can use the example value or provide your own. • When **set in the source system**, the prefix will be prepended to the name of the roles that are read from the SAP HANA Cloud Database Services source system and will be provisioned to the target system with the following name pattern: **`HANA_Cloud_DB_<role_name>`**. This way SAP HANA Cloud Database Services roles in the target system will be distinguished from roles provisioned from other applications. If the property is not set, the SAP HANA Cloud Database Services roles will be read and provisioned to the target system with their actual names. • When **set in the target system**, only roles containing the **`HANA_Cloud_DB_`** prefix in their role name will be provisioned to SAP HANA Cloud Database Services. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be be provisioned to SAP HANA Cloud Database Services.
`hana.cloud.db.user.unique.attribute`	This property defines by which unique attribute(s) an existing user in the target system will be searched and resolved in case Identity Provisioning tries to provision a conflicting user. Default value: *userName*
`ips.delete.threshold.roles`	(Optional) Use this property to control the number of role assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of role assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Value
`ips.delete.threshold.users`	(Optional) Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the SAP HANA Cloud Database Services API URL. For example: `https://api.gateway.orchestration.<cluster>-<datacenter>.hanacloud.ondemand.com`
`User`	Enter the OAuth Client Id, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP HANA Cloud Database Services* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP HANA Cloud Database Services system. For more information, see:

   Manage Transformations [page 2439].

   > ### Note
   >
   > Given that the SAP HANA Database username attribute is immutable and the email is not supported, refer to Handling Specific Attributes for your provisioning scenarios, particularly with Identity Authentication.

Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "('%hana.cloud.db.group.prefix%' === 'null') ||
($.groups[?(@.display =~ /%hana.cloud.db.group.prefix%.*/)] empty false)",
    "mappings": [
      {

        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

5. Add a source system from which to read users and user assignments for a role. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

User Provisioning

1.6.2.30 SAP HANA Database

Follow this procedure to set up SAP HANA Database as a target system.

Prerequisites

- You have credentials for a tenant in SAP Business Technology Platform. For more information, see: Accounts
- You have the necessary connection settings to reach an SAP HANA database.
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only when your SAP HANA DB resides in a remote on-premise system, outside your Neo environment. For more information, see Cloud Connector.

Context

> **Note**
>
> SAP HANA Database is only available as a target system.

SAP HANA Database is a target system (connector), which allows you to log into remote systems that have SAP HANA installed. Only provisioning of entity type **user** is currently supported by this connector. That includes user assignments to roles and all types of catalog and repository privileges (*schema*, *analytic*, *application*). For more information about SAP HANA privileges, see:

SAP HANA: GRANT Statement (Access Control)

SAP HANA: Stored Procedures Used to Grant/Revoke Privileges on Activated Repository Objects

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP HANA Database* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Below are listed all available SAP HANA properties. Some of them can be mandatory and others – optional, depending on your scenario.

Mandatory Properties

Property Name	Description & Value
`ProxyType`	Possible values: • **Internet** • **OnPremise** The proxy type **OnPremise** requires you to provide mappings to your host and port to the Cloud Connector.
(Optional) `Type`	Enter: **HTTP** **Note** This property is mandatory only when your **ProxyType** is **OnPremise**.
`hana.jdbc.db.user`	Name of the SAP HANA Database user
`hana.jdbc.db.password`	(Credential)
`hana.jdbc.db.host`	SAP HANA Database host
`hana.jdbc.db.port`	Default value: **30015**
`hana.jdbc.db.encrypt`	This property enables or disables TLS encryption. Possible values: • true (Default value) • false **Note** For existing systems, the property value defaults to false.
`hana.jdbc.db.validateCertificate`	When set to true, this property specifies that the server certificate is validated. When set to false, the certificate is not validated. Possible values: • true (Default value) • false
(Optional) `CloudConnectorLocationId`	Relevant when the proxy type is *OnPremise*. Use it only if your SAP Business Technology Platform account uses more than one Cloud Connector.

Property Name	Description & Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP HANA Database* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP HANA Database. For more information, see Manage Transformations [page 2439].

   Default transformation:

   Code Syntax

```
{
    "user": {
        "condition": "$.userName EMPTY false",
        "mappings": [
            {
                "sourcePath": "$.userName",
                "targetPath": "$.username"
            },
            {
                "targetPath": "$.password_option.password",
                "scope": "createEntity",
                "functions": [
                    {
                        "type": "randomPassword",
                        "passwordLength": 24,
                        "minimumNumberOfLowercaseLetters": 1,
                        "minimumNumberOfUppercaseLetters": 1,
                        "minimumNumberOfDigits": 1,
                        "minimumNumberOfSpecialSymbols": 0
                    }
                ]
            },
            {
                "ignore": true,
                "constant": true,
```

```
                "targetPath":
"$.password_option.no_force_first_password_change",
                "scope": "createEntity"
            },
            {
                "constant": true,
                "targetPath": "$.deactivate",
                "scope": "deleteEntity"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.username",
                "scope": "deleteEntity"
            },
            {
                "constant": false,
                "targetPath": "$.deactivate"
            },
            {
                "constant": true,
                "targetPath": "$.reset_connect_attempts"
            },
            {
                "ignore": true,
                "constant": true,
                "targetPath": "$.force_password_change"
            },
            {
                "ignore": true,
                "constant": true,
                "targetPath": "$.enable_password_lifetime"
            },
            {
                "ignore": true,
                "constant": true,
                "targetPath": "$.disable_client_connect"
            },
            {
                "constant": "NOW",
                "targetPath": "$.valid_from"
            },
            {
                "constant": "FOREVER",
                "targetPath": "$.valid_to"
            },
            {
                "ignore": true,
                "constant": "1970-01-01 00:00:00.0",
                "targetPath": "$.valid_from"
            },
            {
                "ignore": true,
                "constant": "1970-01-01 00:00:00.0",
                "targetPath": "$.valid_to"
            },
            {
                "ignore": true,
                "constant": "role",
                "targetPath": "$.catalog_permissions[0].type"
            },
            {
                "ignore": true,
                "constant": "MONITORING",
                "targetPath": "$.catalog_permissions[0].name"
            },
            {
                "ignore": true,
                "constant": "ADMIN",
```

```
                "targetPath": "$.catalog_permissions[0].option"
            },
            {
                "ignore": true,
                "constant": "object_privilege",
                "targetPath": "$.catalog_permissions[1].type"
            },
            {
                "ignore": true,
                "constant": "SELECT CDS METADATA",
                "targetPath": "$.catalog_permissions[1].name"
            },
            {
                "ignore": true,
                "constant": "SYS.USERS",
                "targetPath": "$.catalog_permissions[1].on"
            },
            {
                "ignore": true,
                "constant": "role",
                "targetPath": "$.repository_permissions[0].type"
            },
            {
                "ignore": true,
                "constant":
"sap.appcore.auth.p::select_ACCESS_VIEWS_BY_USER",
                "targetPath": "$.repository_permissions[0].name"
            },
            {
                "ignore": true,
                "constant": "application_privilege",
                "targetPath": "$.repository_permissions[1].type"
            },
            {
                "ignore": true,
                "constant": "sap.hana.ide::Catalog",
                "targetPath": "$.repository_permissions[1].name"
            },
            {
                "ignore": true,
                "constant": true,
                "targetPath": "$.repository_permissions[2].revoke"
            },
            {
                "ignore": true,
                "constant": "analytic_privilege",
                "targetPath": "$.repository_permissions[2].type"
            },
            {
                "ignore": true,
                "constant": "_SYS_BI_CP_ALL",
                "targetPath": "$.repository_permissions[2].name"
            }
        ]
    }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.31 SAP Integrated Business Planning

Follow this procedure to set up SAP Integrated Business Planning (in short, SAP IBP) as a target system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Integrated Business Planning, you need to set up the communication (user, system and arrangement) on SAP Integrated Business Planning. You can do it now (as a prerequisite) or in the process of configuring SAP Integrated Business Planning as a target system, as described in step 3.

Context

SAP Integrated Business Planning is a cloud-based solution that combines sales and operations planning (S&OP), forecasting and demand, response and supply, demand-driven replenishment, and inventory planning.

You can use Identity Provisioning to configure SAP IBP as a target system where you can provision entities from a particular source system. The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users** (employee).

SAP Integrated Business Planning provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. By default, the Identity Provisioning service uses API version *1*. The value of the `ibp.api.version` property controls which API you use.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. It supports provisioning **business users** and **role assignments**. In SAP Integrated Business Planning version 1, groups correspond to roles, thus group members are user assignments to a role.

  > **Note**
  >
  > Identity Provisioning cannot create and delete roles in SAP Integrated Business Planning target system. It can only create, update and delete user assignments of a role. Therefore, roles must have been created in SAP Integrated Business Planning system before you run a provisioning job.

For more information on how to update to version *2*, see Update SAP Integrated Business Planning [page 2432].

- When the value is set to *2*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users** with their **assignments** to user groups and roles.
  This version allows you to create, update, and delete user groups, referred to as business user groups in SAP Integrated Business Planning. However, similar to connector version 1, you cannot create or delete groups of type **authorization** (business roles in SAP Integrated Business Planning). You can only update the role assignments.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Integrated Business Planning* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Integrated Business Planning and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Integrated Business Planning target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Integrated Business Planning backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      - When `ibp.api.version=1` is set in Identity Provisioning for the SAP IBP target system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

        > ### Note
        >
        > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.

> The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

- When `ibp.api.version=2` is set in Identity Provisioning for the SAP IBP target system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

> **Note**
>
> The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP IBP system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`ibp.api.version`	The API version which is consumed by the SAP Integrated Business Planning system. By default, Identity Provisioning uses version *1*.
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value

`ibp.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Integrated Business Planning target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved.
	
	The possible values depend on the API version which your SAP Integrated Business Planning system consumes.
	
	• If your system consumes SAP Integrated Business Planning API: Business User, the service searches for an existing user by *personExternalID* and *emails[0].value*.
	According to your use case, choose how to set up the property:
	  • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one.
	If a user with such a *personExternalID* is not found, the creation of the conflicting user fails.
	  • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails.
	If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails.
	• If your system consumes SCIM Interface for IAM, the service searches for an existing user by *userName* , *emails[0].value*, *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes.
	According to your use case, choose how to set up the property:
	  • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails.

Property Name	Description & Value
	• Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *externalId*. If the service finds an existing user with *externalId* , it updates this user with the data of the conflicting one. If a user with such *externalId* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. For more information, see List of Properties [page 80].
`ibp.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP IBP target system. • **true** – the current user roles will be deleted in the target system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target system. See also: Extended Explanation of the *.user.roles.overwrite Properties **Relevant for connector version 1**
(Optional) `ibp.roles.prefix`	This property distinguishes SAP Integrated Business Planning roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **IBP_** You can use the example value or provide your own. When **set in the target system**, only roles containing the **IBP_** prefix in their role name will be provisioned to SAP Integrated Business Planning. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be provisioned to SAP Integrated Business Planning. **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `ibp.group.prefix`	This property distinguishes SAP Integrated Business Planning groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IBP_`** You can use the example value or provide your own. When **set in the target system**, only groups containing the **`IBP_`** prefix in their display name will be provisioned to SAP Integrated Business Planning. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Integrated Business Planning. For more information, see List of Properties [page 80]. **Relevant for connector version 2**
`ibp.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP Integrated Business Planning target system, the creation will fail. In this case, the existing group only needs to be updated. In SAP Integrated Business Planning the uniqueness of a group is defined by the combination of the following two attributes, which are automatically filled in when the target system is created: *externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group'] ['type']*. To resolve the conflict, an existing group must match both of these attributes. If the group matches only one of the attributes, the conflict is not resolved, and group creation will fail. **Note** Although you can define your own unique combination of attributes (for example, *externalId,displayName*), we recommend that you do not modify the automatically filled value of the `ibp.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute *displayName*. **Relevant for connector version 2**

Property Name	Description & Value
(Optional) `ibp.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*. **Relevant for connector version 1**
(Optional)`ibp.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to **true**, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to **false**, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false* **Relevant for connector version 2**
(Optional) `ibp.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20). **Relevant for connector version 1**

Property Name	Description & Value
`ibp.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with **PATCH** requests, and below which they are provisioned with **PUT** request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Note** You can use this property when SAP Integrated Business Planning is based on SCIM Interface for IAM (in short, SCIM API). **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *20000* **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. For more information, see List of Properties [page 80]. **Relevant for connector version 2**
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of user assignments of a role, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP

```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP IBP* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in your SAP IBP. For more information, see:

   Manage Transformations [page 2439]

   SAP Integrated Business Planning API: Business User

   SAP Business Accelerator Hub: SAP IBP

   Integrate Cross-Domain Identity Management

   SCIM Interface for IAM

   Default transformation for connector version 1:

   Code Syntax

```
{
  "user": {
    "condition": "isValidEmail($.emails[0].value) &&
(('%ibp.roles.prefix%' === 'null') || ($.groups[?(@.display =~ /
%ibp.roles.prefix%.*/)] empty false))",
    "mappings": [
      {
        "sourcePath": "$.userName",
        "targetPath": "$.personExternalID"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.personExternalID",
        "optional": true
      },
```

```
      {
        "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['employeeNumber']",
        "targetPath": "$.personExternalID",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",

        "optional": true
      }
    ]
  }
}
```

> **Note**
>
> If you are using SAP Integrated Business Planning version 2511, note that the `timeZone` value is not provided in the `IANA` format required by SCIM. To fix this, you need to manually add the `convertTimezoneCode` function within the `timeZone` mapping, as shown below:

```
{
   "sourcePath":"$.timeZone",
   "optional":true,
   "targetPath":"$.timezone",
   "functions":[
      {
         "type":"convertTimezoneCode",
         "outputFormat":"sap"
      }
   ],
   "defaultValue":"CET"
},
```

Group Uniqueness and Provisioning

In the most common scenario, Identity Authentication connector version 2 or Local Identity Directory is used as the source system for groups and SAP Integrated Business Planning connector version 2 is the target system.

In SAP Integrated Business Planning version 2, the uniqueness of a group is defined by the combination of `externalId` and `type` attributes. The system supports two group types: `userGroup` and `authorization` (role). As a result, two different groups can share the same `externalId` while belonging to different types, potentially causing conflicts when provisioned to the target system.

To avoid conflicts, ensure the following:

- Your SAP Integrated Business Planning target system must be updated to version 2, as described in Update SAP Integrated Business Planning [page 2432] and it must have the group uniqueness property: `ibp.group.unique.attribute`, set with the following combination of values: `externalId,['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`. For more information, see List of Properties [page 80].
- The groups in your Identity Authentication connector version 2 or Local Identity Directory source systems must have a value for the `externalName` attribute, which is mapped to the `externalId` attribute.

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.32 SAP Intelligent Agriculture

Follow this procedure to set up SAP Intelligent Agriculture as a target system.

Prerequisites

- You have onboarded your SAP Intelligent Agriculture tenant as described in the Onboarding with the SAP BTP Cockpit section of the *Administration Guide for SAP Intelligent Agriculture*.
- You have OAuth credentials for SAP Intelligent Agriculture. For more information, see: Getting the Credentials from the SAP Intelligent Agriculture Instance.

Context

SAP Intelligent Agriculture enables agribusinesses to sustainably increase farming efficiency by digitizing their farming processes and services from plan-to-harvest, taking advantage of data science and machine learning capabilities.

You can use Identity Provisioning to configure SAP Intelligent Agriculture as a target system where you can provision users and update group members.

> ⚠ Caution
>
> You can't create or delete groups on SAP Intelligent Agriculture. That means:
>
> - On the attempt to create a group on SAP Intelligent Agriculture, Identity Provisioning will only add new members or update existing ones. Also, if you read a group from the external back-end system, there must be a group with the exact same display name (case sensitive) in the SAP Intelligent Agriculture system. Otherwise, an error will be thrown and the group members will not be updated.
> - On the attempt to delete a group on SAP Intelligent Agriculture, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.

2. Add *SAP Intelligent Agriculture* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter:
`URL`	Enter the URL related to your SAP Intelligent Agriculture system, in format: **`https://*.prod-<region>.ia.agribusiness.cloud.sap`** , where * is the name of your subaccount. For example: **`https://custom-domain.prod-eu10.ia.agribusiness.cloud.sap`**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Intelligent Agriculture instance, in format: **`https://<TENANT>.authentication.<REGION>.hana.ondemand.com/oauth/token`**

Property Name	Value
(Optional) `ia.user.unique.attribute`	When Identity Provisioning attempts to provision a user for the first time, it may detect that this user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user will be searched and resolved. If the service finds a user on the target system via this filter, then the conflicting user will overwrite the existing one. If the service does not find a user on the target system via this filter, the creation will fail. **Default behavior**: The property is missing during system creation. Its default value is *userName* . This means, if the service finds an existing user by a *userName* , it updates this user with the data of the conflicting one. If a user with such *userName* is not found, the creation of the conflicting user fails. **Possible values:** • *userUuid* • *emails* • *userName* • *externalId* Default value: *userName*

Property Name	Value
`ia.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). *displayName*. Currently, it is the only unique attribute that is supported. When set, you can expect the following behavior: • If a group with the given This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is *displayName* is found in the target system, the group that you try to provision will overwrite the existing one. • This property defines by which unique attribute(s) theIf a group with the given *displayName* is not found in the target system, the group that you try to provision will not be created in the target system. **Possible values:** If the property is not specified, the search is done by the default attribute: `displayName`
`ia.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. This means, for example, that if a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false*

Property Name	Value
(Optional) `ia.group.prefix`	This property distinguishes SAP Intelligent Agriculture groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`IA_`** You can use the example value or provide your own. When **set in the target system**, only groups containing the **`IA_`** prefix in their display name will be provisioned to SAP Intelligent Agriculture. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Intelligent Agriculture.
`ia.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Intelligent Agriculture system for entity versioning. **Possible values:** • *true* • *false* Default value: *false*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of group assignments to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of group assignments, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Intelligent Agriculture* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Intelligent Agriculture system. For more information, see Manage Transformations [page 2439].

To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Intelligent Agriculture entity.

Note

When a user is deleted from the SAP Intelligent Agriculture target system, depending on the off-boarding user handling it can be deleted or set to anonymized.

If you try to read such user, you get only its *id* and the other attributes have value `ANONYMOUS`.

If you try to create again a user with the same unique attributes (`userUuid`, `externalId`, `userName`, and `email`) during the configured retention period, the existed entity is restored to its active state. If the create operation requests changes in the values of the attributes, they will be executed after triggering a resync job.

For more information, see Data Retention Manager.

SAP Intelligent Agriculture SCIM API

Default transformation:

Code Syntax

```
{
  "user": {
    "condition": "isValidEmail($.emails[0].value) && ($.userName
EMPTY false) && ($['urn:ietf:params:scim:schemas:extension:sap:2.0:User']
['userUuid'] EMPTY false) && (('%ia.group.prefix%' === 'null') ||
($.groups[?(@.display =~ /%ia.group.prefix%.*/)] empty false))",
    "mappings": [
      {
        "targetPath": "$.id",
        "sourceVariable": "entityIdTargetSystem"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
        "targetPath": "$.schemas[0]"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.middleName",
        "optional": true,
        "targetPath": "$.name.middleName"
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.name.familyName"
```

```
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$.userUuid"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$.externalId"
      },
      {
        "sourcePath": "$.emails[*].value",
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.emails[?(@.value)]"
      }
    ]
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
ia.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
ia.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "mappings": [
      {
        "targetPath": "$.id",
        "sourceVariable": "entityIdTargetSystem"
      },
      {
        "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
        "targetPath": "$.schema[0]"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
ia.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%ia.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ### Note
>
> When Identity Authentication is configured as a source system, the default transformation logic:
>
> - Provisions only groups and user group assignments if they are part of the following predefined group list:
>   - *intagri_Data_Scientist*
>   - *intagri_Farm_Manager*
>   - *intagri_Operator*
>   - *intagri_Operations_Planner*
>   - *intagri_Master_Data_Manager*
>   - *intagri_Administrator*
> - Skips some of the attributes from the identity records.
>
> This way, the transformation logic ensures that the identity data, sent to the Identity Provisioning SCIM REST API, is consistent.

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.33 SAP Jam Collaboration

Follow this procedure to set up SAP Jam Collaboration as a target system.

Prerequisites

You get OAuth credentials for SAP Jam Collaboration. If your SAP Jam tenant is of "SCIM provisioning" type, an OAuth client is automatically created for it, with the name **SCIM API Client**. To find this client:

1. Go to the SAP Jam Collaboration admin panel.
2. Choose *Integrations* > *OAuth Clients*.
3. For *SCIM API Client*, choose *View*.
4. Save the *Key* and *Secret* values – you'll need them later while configuring your SAP Jam Collaboration provisioning system.

To learn more, see: SAP Jam: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a target SAP Jam Collaboration system to provision users and groups.

These target systems consume SCIM 2.0 API provided by SAP Jam Collaboration.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Jam Collaboration* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Jam system, in format: **`https://<SAP_Jam_datacenter>.sapjam.com`** For example: *https://jam4.sapjam.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth client key, created for your SAP Jam tenant (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth client secret, created for your SAP Jam tenant (see **Prerequisites**).
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Jam instance, in format: **`https://<SAP_Jam_datacenter>/api/v1/auth/token`** For example: *https://jam4.sapjam.com/api/v1/auth/token*

Property Name	Description & Value
(Optional) `jam.group.prefix`	This property distinguishes SAP Jam Collaboration groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SJC_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **SJC_** prefix in their display name will be provisioned to SAP Jam Collaboration. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP Jam Collaboration.
(Optional) `ips.failed.request.retry.attempts`	Predefined value: *2*
(Optional) `ips.failed.request.retry.attempts.interval`	Predefined value: *30*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Jam Collaboration* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Jam Collaboration. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Jam Collaboration

- **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. If the entity has e-mail addresses, the first entry will be marked as primary.
- **User off-boarding**:
  - Users can be deleted from the SAP Jam Collaboration system via the SCIM REST API. For more information, see SCIM: Deleting Resources .
  - Users can be deactivated by setting the value of their `active` attribute to **false**. For more information, see SCIM: Singular Attributes

Default transformation:

Code Syntax

```
{
    "user": {
        "condition": "('%jam.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%jam.group.prefix%.*/)] empty false)",
        "mappings": [
            {
                "sourcePath": "$",
                "targetPath": "$"
            },
            {
                "targetPath": "$.id",
                "type": "remove"
            },
            {
                "targetPath": "$.externalId",
                "type": "remove"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id",
                "scope": "deleteEntity"
            },
            {
                "condition": "$.emails[0].length() > 0",
                "constant": true,
                "targetPath": "$.emails[0].primary"
            },
            {
                "constant": false,
                "targetPath": "$.active",
                "scope": "deleteEntity"
            },
            {
                "targetPath": "$.locale",
                "type": "remove"
            },
            {
                "condition": "($.locale EMPTY false) && ($.addresses[?
(@.type == 'work')].country EMPTY false)",
                "sourcePath": "$.locale",
                "targetPath": "$.locale",
                "functions": [
                    {
                        "function": "toLowerCaseString"
                    },
                    {
```

```
                        "function": "concatString",
                        "suffix": "_"
                    },
                    {
                        "function": "concatString",
                        "suffix": "$.addresses[?(@.type ==
'work')].country"
                    }
                ]
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
                "optional": true,
                "targetPath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']['manager']
['value']",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    },
    "group": {
        "ignore": true,
        "condition": "isAttributeWithOptionalPrefix($.displayName,
jam.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
jam.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "sourcePath": "$",
                "targetPath": "$"
            },
            {
                "targetPath": "$.id",
                "type": "remove"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "isAttributeWithMandatoryPrefix(@,
jam.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%jam.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "targetPath": "$.members",
                "type": "remove"
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
```

```
                    {
                        "type": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

1. Before starting a provisioning job, you can first subscribe to the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during your jobs. For more information, see Manage Job Notifications [page 3018].
2. Now, start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

> ⚠ Restriction
>
> Bear in mind the following limitations for the number of sent requests during a provisioning job:
>
> - The **SAP Jam SCIM API** allows up to 13,000 requests per hour and up to 200 requests per minute.
> - The Identity Provisioning service can handle the 200 requests per minute limit. If more requests are sent during the minute, the service will "wait" until it can execute them.

1.6.2.34 SAP Market Communication for Utilities

Follow this procedure to set up SAP Market Communication for Utilities as a target system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Market Communication for Utilities, you need to set up the communication user in SAP BTP ABAP environment. You can do it now (as a prerequisite) or in the process of configuring SAP Market Communication for Utilities as a target system, as described in step 3.

Context

The SAP Market Communication for Utilities application is based on SAP BTP ABAP environment. You can use Identity Provisioning to configure SAP Market Communication for Utilities as a target system to provision entities from a given source system.

This scenario supports writing **users** and **assignments**. In SAP Market Communication for Utilities, groups correspond to roles, thus group members are user assignments of a role.

> ### Note
>
> Identity Provisioning cannot create and delete roles in SAP Market Communication for Utilities target system. It can only create, update and delete user assignments of a role. Therefore, roles must have been created in SAP Market Communication for Utilities target system before you run a provisioning job.
>
> For example, if you try to create or delete a role in SAP Market Communication for Utilities, Identity Provisioning will only add or remove the user assignments of that role, respectively.

The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users** (Employee).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Market Communication for Utilities* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Market Communication for Utilities and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Market Communication for Utilities target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP BTP ABAP environment backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

   For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

   For more information, see Maintain a Communication Arrangement for Inbound Communication

   > **Note**
   >
   > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
   >
   > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP Market Communication for Utilities system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`ips.date.variable.format`	*yyyy-MM-dd*
`maco.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Market Communication for Utilities target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID*

Property Name	Description & Value
`maco.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Market Communication for Utilities target system. • **true** – the current user roles will be deleted in the target system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target system. Default value (if the property is missing during system creation): *true* Default value (if the property appears during system creation): *false* See also: Extended Explanation of the *.user.roles.overwrite Properties
(Optional) `maco.roles.prefix`	This property distinguishes SAP Market Communication for Utilities roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SMC_** You can use the example value or provide your own. When **set in the target system**, only roles containing the **SMC_** prefix in their role name will be provisioned to SAP Market Communication for Utilities. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be be provisioned to SAP Market Communication for Utilities.
(Optional) `maco.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*.

Property Name	Description & Value
(Optional) `maco.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20).
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of user assignments of a role, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://12345-aaaaa-3333.abap.hana.ondemand.com*

`User`=*MyMaCoUser*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`maco.user.roles.overwrite`=*false*

`maco.support.bulk.operation` = *true*

`maco.bulk.operations.max.count` = *50*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default

transformation for the *SAP Market Communication for Utilities* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in SAP Market Communication for Utilities. For more information, see:

Manage Transformations [page 2439]

SAP S/4HANA Cloud API: Business User

Default transformation:

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP S/4HANA Cloud Documentation

1.6.2.35 SAP Marketing Cloud

Follow this procedure to set up SAP Marketing Cloud as a target system.

Prerequisites

To establish the connection between Identity Provisioning and SAP Marketing Cloud, you need to set up the communication (user, system and arrangement) on SAP Marketing Cloud. You can do it now (as a prerequisite) or in the process of configuring SAP Marketing Cloud as a target system, as described in step 3.

Context

You can use SAP Marketing Cloud as a target system to provision entities from a certain source system. This scenario supports writing **users** and **assignments**. In SAP Marketing Cloud, groups correspond to roles, thus group members are user assignments of a role.

> ⓘ Note
>
> Identity Provisioning cannot create and delete roles in SAP Marketing Cloud target system. It can only create, update and delete user assignments of a role. Therefore, roles must have been created in SAP Marketing Cloud system before you run a provisioning job.
>
> For example, if you try to create or delete a role in SAP Marketing Cloud, Identity Provisioning will only add or remove the user assignments of that role, respectively.

The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users** (Employee and Contingent Worker).

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Marketing Cloud* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP Marketing Cloud and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Marketing Cloud target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Marketing Cloud backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

      For more information, see: User Provisioning (with Corporate Identity Provider)

      > ### Note
      >
      > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
      >
      > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
`URL`	Specify the URL to your SAP Marketing Cloud system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value
`marketing.cloud.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP Marketing Cloud target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID*
`marketing.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Marketing Cloud target system. • **true** – the current user roles will be deleted in the target system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target system. See also: Extended Explanation of the *.user.roles.overwrite Properties

Property Name	Description & Value
(Optional) `marketing.cloud.roles.prefix`	This property distinguishes SAP Marketing Cloud roles by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SMKC_** You can use the example value or provide your own. When **set in the target system**, only roles containing the **SMKC_** prefix in their role name will be provisioned to SAP Marketing Cloud. Roles without this prefix in the role name won't be provisioned. If the property is not set, all roles will be be provisioned to SAP Marketing Cloud.
(Optional) `marketing.cloud.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*.
(Optional) `marketing.cloud.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20).
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of user assignments of a role, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://my1234567-api.s4hana.ondemand.com
User=MyMarketingCloudUser
Password=***********
ips.date.variable.format=yyyy-MM-dd
marketing.cloud.user.roles.overwrite = false
marketing.cloud.support.bulk.operation = true
marketing.cloud.bulk.operations.max.count = 50
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Marketing Cloud* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in your SAP Marketing Cloud. For more information, see:

   Manage Transformations [page 2439]

   SAP Marketing Cloud API: Business User

   Default transformation:

   Code Syntax

marketing.cloud.roles.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
marketing.cloud.roles.prefix) && (isRegularGroup() ||
isApplicationSpecificGroup())",
    "mappings": [
      {
        "sourcePath": "$.displayName",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
marketing.cloud.roles.prefix)",
            "function": "replaceFirstString",
            "regex": "%marketing.cloud.roles.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
```

```
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
marketing.cloud.roles.prefix)",
            "function": "replaceFirstString",
            "regex": "%marketing.cloud.roles.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.36 SAP Revenue Growth Management

Follow this procedure to set up SAP Revenue Growth Management as a target system.

Prerequisites

- You have created an SAP Revenue Growth Management consumer application in your SAP Cloud Identity Services tenant and defined a dependency to its API, as described in Configure Integration Between Applications. *UserImport* must be selected for the dependency *API*.
- You have generated API credentials for the consumer application, as described in Generate Credentials to Access the APIs of an Application.

Context

SAP Revenue Growth Management is an SAP BTP SaaS application that provides customers in the Consumer Products industry an easy way to efficiently create, monitor, and maintain account plans.

You can use Identity Provisioning to configure SAP Revenue Growth Management as a target system to provision users and groups. These target systems consume SCIM 2.0 API provided by SAP Revenue Growth Management. For more information, see SAP Revenue Growth Management SCIM API.

> **Note**
>
> Support for groups is intended for future use.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Revenue Growth Management* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
`URL`	Enter the base URL of your SAP Revenue Growth Management system's SCIM API, excluding any path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`Password`	(Credential) Enter the client secret generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`rgm.userImport.api.dependency.name`	Enter the value of the dependency name used in the configuration of the SAP Revenue Growth Management consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. For more information, see Integrating Applications.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.
(Optional) `rgm.user.unique.attribute`	This property defines by which unique attribute(s) an existing user in the target system will be searched and resolved in case Identity Provisioning tries to provision a conflicting user. SAP Revenue Growth Management supports the following unique attributes which are automatically filled in during system creation: **`userName,emails[0].value,externalId`**. If the service finds an existing user by at least one of the unique attributes, it updates this user with the data of the conflicting one. If such a user is not found, the update of the conflicting user fails. If more than one users with these unique attributes are found, the update fails.

Property Name	Description & Value
(Optional) `rgm.group.unique.attribute`	If you try to provision a group that already exists in a target system, the group creation will fail. In this case, the existing group only needs to be updated. This property defines by which unique attribute(s) the existing group will be searched and resolved. The default value is **`['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']`**. Currently, it is the only unique attribute that is supported. If the service finds an existing group by this unique attribute, the group that you try to provision will overwrite the existing one. If such a group is not found, the group that you try to provision will not be created in the target system.
(Optional) `rgm.group.prefix`	This property distinguishes SAP Revenue Growth Management groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **`RGM_`** You can use the example value or provide your own. When **set in the target system**, only groups containing the **`RGM_`** prefix in their display name will be provisioned to SAP Revenue Growth Management. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Revenue Growth Management.
(Optional) `rgm.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for target systems: *false*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Revenue Growth Management* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Revenue Growth Management system. For more information, see:

   Manage Transformations [page 2439].

   SAP Revenue Growth Management SCIM API

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   Code Syntax

```
{
  "user":{
    "condition": "(('%rgm.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%rgm.group.prefix%.*/)] empty false))",
    "mappings":[
      {
       "constant": [
         "urn:ietf:params:scim:schemas:core:2.0:User",
         "urn:ietf:params:scim:schemas:extension:sap:2.0:User"
       ],
       "targetPath": "$.schemas"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['userId']",
        "optional": true,
        "targetPath": "$.externalId"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
```

```
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "optional": true
      },
      {
        "sourcePath": "$.userType",
        "targetPath": "$.userType",
        "optional": true
      },
      {
        "sourcePath": "$.preferredLanguage",
        "targetPath": "$.preferredLanguage",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional":true
      },
      {
        "sourcePath": "$.timezone",
        "targetPath": "$.timezone",
        "optional":true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.addresses",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.addresses"
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']"
      },
      {
        "sourcePath": "$.groups[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.groups[?(@.value)]",
        "functions": [
```

```
          {
            "entityType": "group",
            "type": "resolveEntityIds"
          }
        ]
      }
    ]
  },
  "group": {
   "condition": "isAttributeWithOptionalPrefix($.displayName,
rgm.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
rgm.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "mappings":[
      {
        "targetPath": "$.id",
        "sourceVariable": "entityIdTargetSystem"
      },
      {
       "constant": [
         "urn:ietf:params:scim:schemas:core:2.0:Group",
         "urn:ietf:params:scim:schemas:extension:sap:2.0:Group",
         "urn:sap:cloud:scim:schemas:extension:custom:2.0:Group"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name']",
        "optional": true,
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
rgm.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%rgm.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
rgm.group.prefix)",
            "function": "replaceFirstString",
            "regex": "%rgm.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.members[*].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.members[?(@.value)]",
        "functions": [
          {
            "entityType": "user",
            "type": "resolveEntityIds"
          }
        ]
      },
      {
```

```
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      }
    ]
  }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585].

SAP Revenue Growth Management

1.6.2.37 SAP Sales Cloud and SAP Service Cloud

Follow this procedure to set up SAP Sales Cloud and SAP Service Cloud, formerly known as *SAP Cloud for Customer* (in short, C4C), as a target system.

Prerequisites

To integrate SAP Sales Cloud and SAP Service Cloud with Identity Provisioning, you need to use SAP Cloud Integration (SAP CI). This service provides a package with integration flows (iFlows) for enabling the creation of users and assignment of users to groups via SCIM API in SAP Sales Cloud and SAP Service Cloud.

- To configure SAP Cloud Integration and SAP Sales Cloud and SAP Service Cloud, see: Identity Provisioning in SAP Cloud for Customer using System for Cross-Domain Identity Management (SCIM)
- To set up and use the *SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management* package, see: SAP Business Accelerator Hub: SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management

Context

SAP Sales Cloud and SAP Service Cloud is a cloud-based solution that helps customers manage day-to-day sales and service interactions by sending and receiving signals between front- and back-office solutions and providing a single view of the customer.

You can use Identity Provisioning to configure SAP Sales Cloud and SAP Service Cloud as a target system where you can provision users and group members from source systems. Keep in mind that once you have provisioned the entities to SAP Sales Cloud and SAP Service Cloud, a *business user* and an *employee* are created for every provisioned user. The business user is required for the provisioned user to log into the SAP Sales Cloud and SAP Service Cloud system.

The cloud-based solution provides different APIs for integration with Identity Provisioning, leading to different connector versions for each API. Currently, the following connector versions are available: Version 1 (SOAP-based API), which is deprecated, Version 2 (SOAP-based API), Version 3 (SCIM 2.0 based API) and Version 4 (SCIM 2.0 based API), which is applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only.

Each connector version supports specific attribute mappings in transformations and requires particular properties. The latest version is set as the default.

Version 1 (SOAP-based API)

> **Note**
>
> The SOAP-based API version 1 is deprecated.

When created via connector version 1, users are initially transferred to a staging area, and then can be replicated to the C4C system manually or via a job, depending on your tenant setup. This API version is SOAP based. In the SAP Sales Cloud and SAP Service Cloud admin console you can distinguish it by its name – */humancapitalmanagementmasterd6*.

To learn how to replicate users (using API v.1), see: Employee Master Data Replication

Version 2 (SOAP-based API)

When using connector version 2, users are created immediately – there is no need to transfer them to a staging area. This API version is SOAP based. In the C4C admin console, you can distinguish it by its name */employeereplicationin2*.

Version 3 (SCIM 2.0 based API)

When using connector version 3, users are created immediately. There is no need to transfer them to a staging area. For more information, refer to *Identity Provisioning in SAP Cloud for Customer using a System for Cross-domain Identity Management (SCIM)* package in the *Prerequisites* section.

Version 4 (Applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only)

When using connector version 4 (SCIM 2.0 based API), only users of type `Employee` are provisioned. This version introduces an enhanced SCIM API that no longer requires SAP Cloud Integration. It supports patch operations and provisioning of application-specific groups. Conflict resolution is handled using not only the username but also based on the user's email and a combination of both username and email.

> ### Note
>
> If you have access to all API versions, you must use **separate** provisioning systems for each version, to avoid data inconsistency errors.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Sales Cloud and SAP Service Cloud* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter SAP Cloud Integration runtime URL. See: How to Get SAP Cloud Integration Runtime URL
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`OAuth2TokenServiceURL`	Enter the URL to the access token provider service. For example: `https://<c4c_instance>/auth/token` endpoint. SAP Sales Cloud and SAP Service Cloud support OAuth token-based authentication, enabling you to obtain an access token using either basic authentication (by setting `User` and `Password`) or certificate authentication. **Relevant for connector version 4**
`User`	Enter SAP Cloud Integration user ID to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**

Property Name	Description & Value
`Password`	(Credential) Enter SAP Cloud Integration password to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**
`c4c.api.version`	The version of the SAP Sales Cloud and SAP Service Cloud API you use. • **1** - SOAP-based API (deprecated) • **2** - SOAP-based API • **3** - SCIM 2.0 based API • **4** - SCIM 2.0 based API (enhanced) **Note** After you set up the communication arrangement, you can determine the API version used by your SAP Sales Cloud and SAP Service Cloud system. It represents the ID at the end of your generated URL – the name of API v.1 is *humancapitalmanagementmasterd6*, and for API v.2 is *employeereplicationin2*.
`RemoteSystemID`	Enter the system instance ID, configured for the communication system setting in the C4C system. **Relevant for connector version 1** (deprecated)
`RecipientPartyID`	Enter the recipient system name. Example: **0011SAP** **Relevant for connector version 2**
`SenderPartyID`	Enter the name of the sender system name. It's equal to the value of property RemoteSystemID from version 1. For example: **IPS** **Relevant for connector version 2**

Property Name	Description & Value
`c4c.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value: *false* **Relevant for connector version 4**
`c4c.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. Default value in all versions: *userName* Supported values in version 4: • userName • emails[0].value • userName,emails[0].value
`c4c.group.unique.attribute`	If Identity Provisioning tries to provision a group that already exists in the target system (a conflicting group), this property defines the unique attributes by which the existing group will be searched and resolved. Default value: *displayName*
(Optional) `c4c.group.prefix`	This property distinguishes SAP Sales Cloud and SAP Service Cloud groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **C4C_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **C4C_** prefix in their display name will be provisioned to SAP Sales Cloud and SAP Service Cloud. Groups without this prefix in the display name won't be provisioned. If the property is not set, the SAP Sales Cloud and SAP Service Cloud groups will be read and provisioned to the target system with their actual display names.

Property Name	Description & Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Sales Cloud and SAP Service Cloud* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in C4C. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: C4C

   SAP Cloud for Customer OData API v2 Reference

   Default transformation for connector version 1: Deprecated

   Code Syntax

```
/* Attribute RemoteObjectID stores the user name from the source system
into C4C. */
{
   "user": {
       "mappings": [
           {
        "sourcePath": "$.userName",
        "targetPath": "$.RemoteObjectID"
       },
/* Statements that start with PersonalDetails are related to the employee
created in C4C. */
       {
          "sourceVariable": "currentDate",
          "targetPath": "$.PersonalDetails.ValidityPeriod.StartDate",
          "functions": [
               {
                  "type": "manipulateDate",
                  "targetDateFormat": "yyyy-MM-dd"
               }
            ]
```

```
        },
      {
          "constant": "9999-12-31",
          "targetPath": "$.PersonalDetails.ValidityPeriod.EndDate"
        },
        {
          "sourcePath": "$.name.givenName",
          "optional": true,

        "sourcePath": "$.name.familyName",
        "targetPath": "$.PersonalDetails.FamilyName"
    },
/* Statements that start with EmployeeType are supported by the C4C system
only for internal employees.
(Service agents are not supported as EmployeeType. The supported employee
types are mandatory and relevant only to lean employees).
The value of the currentDate variable (the date when the provisioning is
executed) is set as validity start date of the employee.
In the default transformation statement, it's converted to the format
required by C4C via a transformation function. */
       {
          "sourceVariable": "currentDate",
          "targetPath": "$.EmployeeType.ValidityPeriod.StartDate",
          "functions": [
             {
              "type": "manipulateDate",
              "targetDateFormat": "yyyy-MM-dd"
             }
             ]
           },
           {
               "constant": "9999-12-31",
               "targetPath": "$.EmployeeType.ValidityPeriod.EndDate"
           },
           {
               "sourcePath": "$.userName",
               "targetPath": "$.Identity.ID"
           },
           {
               "constant": "false",
               "targetPath": "$.Identity.UserAccountsInactiveIndicator"
           },
           {
               "sourcePath": "$.phoneNumbers[?(@.type == 'mobile')].value",
               "optional": true,
               "targetPath":
"$.WorkplaceAddress.MobilePhoneNumberDescription"
           },
           {
               "sourcePath": "$.phoneNumbers[?(@.type == 'work')].value",
               "optional": true,
               "targetPath": "$.WorkplaceAddress.PhoneNumberDescription"
           },
           {
               "sourcePath": "$.emails[0].value",
               "optional": true,
               "targetPath": "$.WorkplaceAddress.EmailURI"
           }
       ]
    }
}
```

If you use the first version of the SAP Sales Cloud and SAP Service Cloud API (SOAP based) – *humancapitalmanagementmasterd6* – your systems will be created with *c4c.api.version=1*. You need to use

the transformation below and specify the mandatory attribute *RemoteSystemID*. The following interface is used for replicating employee master data to SAP Sales Cloud and SAP Service Cloud: Inbound Service HumanCapitalManagementMasterDataReplicationEmployeeMasterDataReplicationIn. Along with replicating employees in SAP Sales Cloud and SAP Service Cloud, a business user is created for every user.

Default transformation for connector version 2

Code Syntax

```
{
    "user": {
        "condition" : "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User'].employeeNumb
er EMPTY false",
        "mappings": [
            {
                "targetPath": "$.ReceiverEmployeeID",
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User'].employeeNumb
er"
            },
            {
                "targetPath": "$.BusinessPartnerID",
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User'].employeeNumb
er"
            },
            {
                "targetPath": "$.EmployeeType.ValidityPeriod.StartDate",
                "sourceVariable": "currentDate",
                "functions": [
                    {
                        "type": "manipulateDate",
                        "targetDateFormat" : "yyyy-MM-dd"
                    }
                ]
            },
            {
                "targetPath": "$.EmployeeType.ValidityPeriod.EndDate",
                "constant": "9999-12-31"
            },
            {
                "targetPath": "$.Common.Name.GivenName",
                "sourcePath": "$.name.givenName",
                "optional": true
            },
            {
                "targetPath": "$.Common.Name.FamilyName",
                "sourcePath": "$.name.familyName"
            },
/* You can set a custom namespace for an attribute. For example, if your
namespace prefix is called a123,
enter the following lines in your transformation:
          {
            "targetPath": "$['a123:PersonalDetails']
['a123:FamilyName']",
            "sourcePath": "$.name.familyName"
          }
When sending the request to C4C, the Identity Provisioning service will
transform this data into XML elements, as follows:
            <a123:PersonalDetails>
                <a123:FamilyName>...</FamilyName>
            </a123:PersonDetails>   */

            {
```

```
                "targetPath": "$.Identity.IdentityID",
                "sourcePath": "$.userName"
            },
            {
                "targetPath": "$.Identity.UserAccountsInactiveIndicator",
                "constant": "false"
            },
            {
                "condition": "$.active == false",
                "targetPath": "$.Identity.UserAccountsInactiveIndicator",
                "constant": "true"
            },
            {
                "targetPath":
"$.WorkplaceAddress.MobilePhoneNumberDescription",
                "sourcePath": "$.phoneNumbers[?(@.type ==
'mobile')].value",
                "optional": true
            },
            {
                "targetPath": "$.WorkplaceAddress.PhoneNumberDescription",
                "sourcePath": "$.phoneNumbers[?(@.type == 'work')].value",
                "optional": true
            },
            {
                "targetPath": "$.WorkplaceAddress.EmailURI",
                "sourcePath": "$.emails[0].value",
                "optional": true
            },
            {
                "constant": "SALES_REP",
                "targetPath": "$.Identity.BusinessRole[0].ID"
            },
            {
                "constant": "SALES_MANAGER",
                "targetPath": "$.Identity.BusinessRole[1].ID"
            }
        ]
    }
}
```

If you want to use the second C4C API (SOAP based) – *employeereplicationin2* – you have to set *c4c.api.version=2*, change the transformation with the one above, and specify the two mandatory attributes – *RecipientPartyID* and *SenderPartyID*.

Default transformation for connector version 3

Code Syntax

```
{
  "user": {
    "condition": "('%c4c.group.prefix%' === 'null') || ($.groups[?
(@.display =~ /%c4c.group.prefix%.*/)] empty false)",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath": "$.emails[*].value",
```

```
        "preserveArrayWithSingleElement": true,
        "targetPath": "$.emails[?(@.value)]",
        "optional": true
      },
      {
        "constant": "work",
        "targetPath": "$.emails[0].type"
      },
      {
        "sourcePath": "$.userType",
        "targetPath": "$.userType",
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.name.givenName"
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.name.familyName"
      },

                ]
            }
        ]
    }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.38 SAP Signavio Process Transformation Suite

Follow this procedure to set up SAP Signavio Process Transformation Suite as a target system.

Prerequisites

> **Note**
>
> The initial setup of SAP Signavio Process Transformation Suite is completed during the onboarding process. This setup includes establishing a connection between Identity Provisioning and SAP Signavio

Process Transformation Suite using certificate-based authentication. Any changes needed after the initial setup should be processed through a support incident.

Context

SAP Signavio Process Transformation Suite helps you understand, improve, and transform your business processes – fast and at scale – with a cloud-based process management platform.

You can use Identity Provisioning to configure SAP Signavio Process Transformation Suite as a target system where you can provision users and groups from source systems. When provisioning users, ensure that the `userName` attribute is formatted as a valid email address.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP Signavio Process Transformation Suite* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	The URL to the SCIM API of your SAP Signavio Process Transformation Suite system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`sig.tenant.id`	The identifier of SAP Signavio Process Transformation Suite tenant

Property Name	Value
`sig.user.unique.attribute`	This property defines the unique attributes used to search and resolve an existing user when Identity Provisioning attempts to provision a user that already exists in the target system (a conflicting user). Default value: *userName* If the service finds an existing user with the same *userName*, it updates that user with the data from the conflicting user. However, if no user with that *userName* exists, the creation of the conflicting user fails.
`sig.group.unique.attribute`	This property defines the unique attributes used to search and resolve an existing group when Identity Provisioning attempts to provision a group that already exists in the target system (a conflicting group). Default value: *displayName*
`sig.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value: *false*
