`sig.group.prefix`	This property distinguishes SAP Signavio Process Transformation Suite groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: SIG_ You can use the example value or provide your own. When **set in the target system**, only groups containing the SIG_ prefix in their display name will be provisioned to SAP Signavio Process Transformation Suite. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP Signavio Process Transformation Suite.

Property Name	Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Signavio Process Transformation Suite* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Signavio Process Transformation Suite system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP Signavio Process Transformation Suite entity.

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "($.emails EMPTY false) &&
isValidEmail($.emails[*].value) && (('%sig.group.prefix%' === 'null') ||
($.groups[?(@.display =~ /%sig.group.prefix%.*/)] empty false))",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:core:2.0:User",

        "optional": true
      }
    ]
  }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP Signavio Process Transformation Suite

1.6.2.39 SAP S/4HANA Cloud Public Edition

Follow this procedure to set up SAP S/4HANA Cloud Public Edition as a target system.

Prerequisites

To establish the connection between Identity Provisioning and SAP S/4HANA Cloud Public Edition, you need to set up the communication (user, system and arrangement) on SAP S/4HANA Cloud Public Edition. You can do it now (as a prerequisite) or in the process of configuring SAP S/4HANA Cloud Public Edition as a target system, as described in step 3.

Context

SAP S/4HANA Cloud Public Edition is a complete enterprise resource planning (ERP) system with built-in intelligent technologies and advanced analytics.

You can use Identity Provisioning to configure SAP S/4HANA Cloud Public Edition as a target system where you can provision users and group members from source systems of your choice.

SAP S/4HANA Cloud Public Edition provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `s4hana.cloud.api.version` property controls which API you use. By default, the Identity Provisioning service uses API version *1*.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. In SAP S/4HANA Cloud Public Edition connector version 1, groups correspond to business roles, thus group members are user assignments of a business role.

  > ### Note
  >
  > Identity Provisioning cannot create and delete business roles in SAP S/4HANA Cloud Public Edition target system. It can only create, update and delete user assignments of a role. Therefore, business roles must have been created in SAP S/4HANA Cloud Public Edition system before you run a provisioning job.

  When SAP S/4HANA Cloud Public Edition is configured as a target system, the integration with a human resource (HR) system is active by default. In this case, the synchronization of business partners is managed by the HR system and SAP S/4HANA Cloud Public Edition. Identity Provisioning can only be used for managing business users (login users and their login information, such as date/time preferences) and role assignments.
  In SAP S/4HANA Cloud Public Edition, business partners are the central master data objects that hold the complete person profile in the SAP S/4HANA Cloud Public Edition. For example, business partners with role `Employee` and `Contingent Worker`. Business users are persons who can log on to SAP S/4HANA Cloud Public Edition system to complete business tasks.

- When the value is set to *3*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users** with their **assignments** to user groups and roles.
  This version allows you to create, update, and delete user groups, referred to as business user groups in SAP S/4HANA Cloud Public Edition. However, similar to connector version 1, you cannot create or delete groups of type **authorization** (business roles in SAP S/4HANA Cloud Public Edition). You can only update the role assignments. For more information, see Groups.

  > ⓘ Note
  >
  > For groups of the **userGroup** type, a user can have only one assignment at a time. If a user is assigned to a new group of the **userGroup** type, the previous assignment of the same type will be automatically removed, and the user will be exclusively assigned to the newly selected group.

For more information on how to update to version *3*, see Update SAP S/4HANA Cloud Public Edition [page 2435].

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP S/4HANA Cloud Public Edition* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP S/4HANA Cloud Public Edition and configure your authentication method (basic or certificate-based).

   > ⓘ Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP S/4HANA target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP S/4HANA backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      - When `s4hana.cloud.api.version=1` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition target system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

> **Note**
>
> The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
>
> The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

- When `s4hana.cloud.api.version=3` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition target system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

> **Note**
>
> The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP S/4HANA Cloud Public Edition API URL. You can find the correct URL in the *API-URL* field of the communication arrangement set up for the communication scenario used. For example: `https://my123456-api.s4hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`s4hana.cloud.api.version`	The version of the system API you use. By default, Identity Provisioning uses version *1*. Version *1* means your SAP S/4HANA Cloud Public Edition system consumes SAP S/4HANA Cloud Public Edition API: Business User. Version *3* means your SAP S/4HANA Cloud Public Edition system consumes System for Cross-domain Identity Management (SCIM) API.
`s4hana.cloud.hr.switch.active`	Defines whether the human resources (HR) integration is active or not. The property is set to `true` by default. This means that the synchronization of business partners is managed by the HR system and SAP S/4HANA Cloud Public Edition. When set to `false`, synchronization is handled by the identity management system instead. **Possible values:** • true (default) • false **Relevant for connector version 1**
`s4hana.cloud.hr.switch.dependent.role.codes`	A default property. As a comma-separated value, add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your *read* and *write* transformations. By default, the following codes are added to your system: **BUP003 and BBP005**. That means, your HR integration will support *employees* and *contingent workers*. **Relevant for connector version 1**
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value

`s4hana.cloud.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP S/4HANA Cloud Public Edition target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved.
	
	Note
	You can configure this property only when the integration between a human resource (HR) system and SAP S/4HANA Cloud Public Edition target system is **OFF**.
	
	The possible values of this property depend on the API version which your SAP S/4HANA Cloud Public Edition system consumes.
	
	Possible values:
	• If your system consumes SAP S/4HANA Cloud Public Edition API: Business User, the service searches for an existing user by *personExternalID* and *emails[0].value*.
	According to your use case, choose how to set up the property:
	  • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID* , it updates this user with the data of the conflicting one.
	If a user with such a *personExternalID* is not found, the creation of the conflicting user fails.
	  • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails.
	If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails.
	• If your system consumes System for Cross-domain Identity Management (SCIM) API, the service searches for an existing user by *userName* , *emails[0].value*, *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes.

Property Name	Description & Value
	According to your use case, choose how to set up the property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *externalId*. If the service finds an existing user with *externalId* , it updates this user with the data of the conflicting one. If a user with such *externalId* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. For more information, see List of Properties [page 80].
(Optional) `s4hana.cloud.group.prefix`	This property distinguishes SAP S/4HANA Cloud Public Edition groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **S4HANACLOUD_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **S4HANACLOUD_** prefix in their display name will be provisioned to SAP S/4HANA Cloud Public Edition. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to SAP S/4HANA Cloud Public Edition. For more information, see List of Properties [page 80]. **Relevant for connector version 3**

Property Name	Description & Value
`s4hana.cloud.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the SAP S/4HANA Cloud Public Edition target system, the creation will fail. In this case, the existing group only needs to be updated. In SAP S/4HANA Cloud Public Edition the uniqueness of a group is defined by the combination of the following two attributes, which are automatically filled in when the target system is created: *externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group'] ['type']*. To resolve the conflict, an existing group must match both of these attributes. If the group matches only one of the attributes, the conflict is not resolved, and group creation will fail. **Note** Although you can define your own unique combination of attributes (for example, *externalId,displayName*), we recommend that you do not modify the automatically filled value of the `s4hana.cloud.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute *displayName*. **Relevant for connector version 3**

Property Name	Description & Value
`s4hana.cloud.patch.group.members.above.threshold`	Defines the threshold number of group members above which they are provisioned on batches with **PATCH** requests, and below which they are provisioned with **PUT** request. Setting this property allows you to avoid timeouts when updating groups with a large number of group members. The expected value is a positive integer without any separators, such as a space, comma, or period. **Possible values**: integer Default value: *20000* Minimum value: *1* Maximum value: *20000* **Note** If this property is not configured, the default value is applied automatically. The value must be greater than *0* to ensure proper provisioning of group members. For more information, see List of Properties [page 80]. **Note** Regardless of the threshold number you define, when removing group members in SAP S/4HANA Cloud Public Edition, the maximum number of members which can be removed per one **PATCH** request is 50. **Relevant for connector version 3**
`s4hana.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP S/4HANA Cloud Public Edition target system. - **true** – the current user roles will be deleted in the target system, and the user will be updated only with the roles provisioned by the service. - **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the target system. See also: Extended Explanation of the *.user.roles.overwrite Properties **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `s4hana.cloud.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*. **Relevant for connector version 1**
(Optional) `s4hana.cloud.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to **true**, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to **false**, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false* **Relevant for connector version 3**
(Optional) `s4hana.cloud.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20). **Relevant for connector version 1**
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of user assignments of a role to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of user assignments of a role, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

`s4hana.cloud.support.bulk.operation` = *true*

`s4hana.cloud.bulk.operations.max.count` = *50*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. Identity Provisioning offers a default transformation for the *SAP S/4HANA Cloud Public Edition* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in SAP S/4HANA Cloud Public Edition. For more information, see:

   Manage Transformations [page 2439]

   SAP S/4HANA Cloud API: Business User

   System for Cross-domain Identity Management (SCIM)

   Integrate Cross-Domain Identity Management

Default transformation for connector version 1:

          }
        ]
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true,
        "defaultValue": "userGroup"
      },
      {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true
      }
    ]
  }
}
```

Group Uniqueness and Provisioning

In the most common scenario, Identity Authentication connector version 2 or Local Identity Directory is used as the source system for groups and SAP S/4HANA Cloud Public Edition connector version 3 is the target system.

In SAP S/4HANA Cloud Public Edition version 3, the uniqueness of a group is defined by the combination of `externalId` and `type` attributes. The system supports two group types: `userGroup` and `authorization` (role). As a result, two different groups can share the same `externalId` while belonging to different types, potentially causing conflicts when provisioned to the target system.

To avoid conflicts, ensure the following:

- Your SAP S/4HANA Cloud Public Edition target system must be updated to version 3, as described in Update SAP S/4HANA Cloud Public Edition [page 2435] and it must have the group uniqueness property: `s4hana.cloud.group.unique.attribute`, set with the following combination of values: `externalId,['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`. For more information, see List of Properties [page 80].
- The groups in your Identity Authentication connector version 2 or Local Identity Directory source systems must have a value for the `externalName` attribute, which is mapped to the `externalId` attribute.

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].

- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP S/4HANA Cloud Documentation

1.6.2.40 SAP S/4HANA for procurement planning

Follow this procedure to set up SAP S/4HANA for procurement planning as a target system.

Prerequisites

You have technical credentials for SAP S/4HANA for procurement planning. See: Onboadring

Context

SAP S/4HANA for procurement planning is a cloud-based solution designed to help you plan procurement activities with regard to the time schedule, as well as the investment planning of items based on a central bill of material.

You can use Identity Provisioning to configure SAP S/4HANA for procurement planning as a target system where you can provision **users** from source systems.

> **Note**
>
> SAP S/4HANA for procurement planning does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP S/4HANA Procurement Planning* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API of your SAP S/4HANA for procurement planning system without path information. For example: `https://procplanning-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP S/4HANA for procurement planning system.
`Password`	Enter the OAuth Client Secret, created for your SAP S/4HANA for procurement planning system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://procplansecurity.authentication.eu10.hana.ondemand.com/oauth/token**

Property Name	Value
`s4hana.pp.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName*
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA for procurement planning* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP S/4HANA for procurement planning system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP S/4HANA for Procurement Planning

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP S/4HANA for procurement planning entity.

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
             {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
             },
             {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
             },
             {
                 "sourcePath": "$.displayName",
                 "targetPath": "$.displayName"
             },
             {
                 "sourcePath": "$.active",
                 "targetPath": "$.active"
             },
             {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails"
            },
            {
                "condition": "$.emails[0].length() > 0",
                "targetPath": "$.emails[0].primary",
                "constant": true
            },
            {
                "targetPath": "$.id",
                "type": "remove"
            },
            {
                "type": "remove",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']"
            }
        ]
    }
}
```

5. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

SAP S/4HANA for procurement planning – Product Page

1.6.2.41 SAP S/4HANA On-Premise

Follow the procedure to set up SAP S/4HANA on-premise (also valid for SAP S/4HANA Cloud, private edition) as a target system.

Prerequisites

> ⓘ Note
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have technical credentials (user and password) for SAP S/4HANA on-premise.
- The SAP S/4HANA on-premise system is version **1809** or higher.
- You have configured your SOA Manager to directly call the following Web services:
  - **ManageBusinessUserIn**
  - **QueryBusinessUserIn**

  For more information, see: Setting Up SOA Manager.

Context

You can use Identity Provisioning to configure SAP S/4HANA on-premise as a target system where you can provision **users** from source systems.

This scenario requires that you first provision the users to SAP AS ABAP. The created ABAP users will have PFCG roles assigned. Once this is done, the users will have ABAP IDs. Then, after the provisioning to SAP S/4HANA on-premise, business users will be created and linked to the relevant ABAP IDs via the *User_Assignment* attribute.

In SAP S/4HANA, a business user is defined as a natural person who is represented by a business partner and a link to a user in the system. Actually, the business user is an AS ABAP (SU01) user who also has a one-to-one relation to a corresponding business partner. For more information on the identity model for business users, see SAP Note 2570961.

SAP S/4HANA on-premise supports provisioning of users with *User UUID* attribute which is generated by Identity Authentication at user creation. The attribute mapping is handled by the default transformation of AS ABAP connector. For more information, see: SAP Application Server ABAP [page 987].

Provisioning of **roles** (considered as *groups*) is also handled by the default transformation of SAP AS ABAP connector.

According to your use case, you can decide whether to use SAP S/4HANA on-premise with HR (human resources) integration active or not.

- System with HR integration – When the HR integration is active, business users in SAP S/4HANA on-premise are automatically created and managed by the HR system (for example, an external data source, such as an identity management system). The Identity Provisioning service can manage only the user-related login information, such as date/time preferences, or role assignments.
  This means that once the users are provisioned to AS ABAP, you need to run the provisioning to SAP S/4HANA on-premise, so that business users (employee, collaboration user, contingent worker, resource) can be linked to the AS ABAP users via the *User_Assignment* attribute.

  > ### Note
  >
  > Identity Provisioning cannot delete business users in SAP S/4HANA Cloud on-premise system with active HR integration. Deletion is possible only in case of erroneous user assignments to business partners. For more information, see 2568251.

- System without HR integration – lean business users will be created after the provisioning job, and the AS ABAP users will be linked to them. The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users**.

To enable HR integration, you need to specify the relevant property in the system configuration. See **step 4** from the procedure below.

Procedure

1. Open the Cloud Connector to add an access control system mapping for **SAP S/4HANA On-Premise**. This is needed to allow the Identity Provisioning service to access SAP S/4HANA On-Premise as a back-end system on the intranet. To learn how, see: Configure Access Control (HTTP)

2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *SAP S/4HANA On-Premise* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP S/4HANA On-Premise system.
`ProxyType`	Enter: *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user for SAP S/4HANA On-Premise.
`Password`	(Credential) Enter the password for the SAP S/4HANA On-Premise technical user.
`s4hana.onprem.hr.switch.active`	This property is enabled by default. Possible values: • **true** (default value) – HR integration is enabled for your system • **false** – HR integration is disabled for your system
`s4hana.onprem.hr.switch.dependent.role.codes`	A default property. Relevant only for systems with activated HR integration, that is if `s4hana.onprem.hr.switch.active` = *true*. As a comma-separated value, add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your *read* and *write* transformations. By default, the following codes are added to your system: **BUP003, BBP005, BUP012, WFM001**. That means, your HR integration will support *employees*, *contingent worker*, *collaboration user*, and *resource*.
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value
`s4hana.onprem.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the SAP S/4HANA On-Premise target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. According to your use case, choose how to set up this property: • Default behavior: This property does not appear in the UI during system creation. Its default value is *personExternalID*. That means, if the service finds an existing user by a *personExternalID*, it updates this user with the data of the conflicting one. If a user with such a *personExternalID* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user matching both unique attributes *email* and *personExternalID*, it updates this user with the data of the conflicting one. If the service finds an existing user matching only the *email*, the update of the existing user fails. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. Possible values: • *personExternalID* • *emails[0].value* Default value: *personExternalID*
(Optional)`s4hana.onprem.sap-client`	Use this property if you want to specify a particular AS ABAP client to use as the **sap-client** URL parameter. If this property is not specified, the URL will open your default AS ABAP client. To learn more, see: Specifying the Client For more information about **sap-client**, see: SAP URL Parameters
(Optional)`CloudConnectorLocationId`	Relevant when the `ProxyType` property is set to *OnPremise*. Use it in case your SAP Business Technology Platform account uses more than one Cloud Connector or when the Cloud Connector uses `LocationID`.

Property Name	Description & Value
(Optional) `s4hana.onprem.support.bulk.operation`	Set this property to *true* if you want to enable bulk operations for provisioning entities. That means, the Identity Provisioning service can write, update, and delete multiple users or groups in a single request. For more information, see: APIs for Business User Management If not specified, the default value is *false*.
(Optional) `s4hana.onprem.bulk.operations.max.count`	If you have enabled the bulk operations, you can use this property to set the number of users to be provisioned per request. The default value, if not specified, is *20*. The maximum value is **100**. If you enter a number larger than 100, the service will replace it with the default value (20).
(Optional) `ips.delete.threshold.roles`	Use this property to control the number of roles to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of roles, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=OnPremise
URL=http://aaa777.myhost:1234
User=MYS4HANAUSER
Password=************
ips.date.variable.format=yyyy-MM-dd
s4hana.onprem.hr.switch.active=true
s4hana.onprem.hr.switch.dependent.role.codes=BUP003,BBP010,BBP005
s4hana.onprem.sap-client=101
s4hana.onprem.support.bulk.operation = true
s4hana.onprem.bulk.operations.max.count = 50
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA On-Premise* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules depending on your setup of entities in SAP S/4HANA On-Premise. For more information, see:

   Manage Transformations [page 2439]

   APIs for Business User Management

   Default transformation:

   Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.userName",
        "targetPath": "$.personExternalID"

        "functions": [
          {
            "function": "toUpperCaseString"
          }
        ]
      },
      {
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.workplaceInformation.emailAddress",
        "optional": true
      }
    ]
  }
}
```

6. Now, add a source system from which to read users and roles. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP S/4HANA On-Premise
APIs for Business User Management

1.6.2.42 SAP SuccessFactors

Follow this procedure to set up SAP SuccessFactors as a target system.

Prerequisites

- You are using **SAP SuccessFactors HCM Suite OData API**
  You have created a technical user with permissions to **call** the SAP SuccessFactors HCM Suite OData API to **import** employee data into an SAP SuccessFactors system. For more information, see Permissions, Setting Up an API User for Sync Jobs in SAP SuccessFactors and URI Conventions (OData Version 2.0) .
- You are using **SAP SuccessFactors Workforce SCIM API**
  Consumers of the SAP SuccessFactors Workforce SCIM API can either create a technical user and assign the necessary permissions, or use the predefined technical user with built-in permissions for communication between SAP SuccessFactors and Identity Provisioning using certificate authentication. For more information, see Upgrade to X.509 Certificate-Based Authentication for Incoming Calls and Permissions.

Context

SAP SuccessFactors provides two APIs for its integration with Identity Provisioning: SAP SuccessFactors HCM Suite OData API and SAP SuccessFactors Workforce SCIM API. The value of `sf.api.version` property controls which API you use.

- When the value is set to **1**, or the property is not defined - SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. This is the default value. SAP SuccessFactors source systems created before the introduction of `sf.api.version` property, use OData API.
  This version allows you to create and update **users**, as well as update **dynamic groups** and **group members**. To update a group from the source system, a group with the same name should already exist in SAP SuccessFactors.

  > ⚠ Restriction
  >
  > Note the following restrictions when using SAP SuccessFactors HCM Suite OData API:
  >
  > - You cannot *create* or *delete* groups as these operations are currently not supported.
  > - Managing SAP SuccessFactors **static groups** is not supported.

- When the value is set to **2** - SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used.
  This version allows you to provision static permission groups and user's group assignments. Provisioning of user's group assignments from a given source system to SAP SuccessFactors target system is possible if the user is an active employee with a work assignment and has a value of the `perPersonUuid` attribute. Alternatively, `personIdExternal` could be used as a fallback attribute.

This requires that SAP SuccessFactors users are first provisioned with the attribute to the given system, for example Identity Authentication, where the `perPersonUuid` must be mapped to a custom attribute. Afterwards, assigning users to groups in Identity Authentication and running a provisioning job would result in correct user assignments in SAP SuccessFactors target.
To update a group from the source system, a group with the same name should already exist in SAP SuccessFactors.

> **⚠ Restriction**
>
> Note the following restrictions when using SAP SuccessFactors Workforce SCIM API:
>
> - You cannot *create* or *delete* groups using the `Groups` APIs.
> - The `Groups` patch API only supports updating membership of static permission groups.
>
> For more information, see Overview of SAP SuccessFactors Workforce System for Cross-Domain Identity Management API.

For more information about the difference between static and dynamic groups in SAP SuccessFactors, see Permission Groups.

For more information on how to update to version 2, see Update Connector Version [page 2424].

You can configure *SAP SuccessFactors* as a target system to provision entities from a given source system. With regards to user termination, it is a standard HR process that is triggered from the SAP SuccessFactors system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP SuccessFactors* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP SuccessFactors and configure your authentication method (basic or certificate-based).

   > **ⓘ Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP SuccessFactors target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip this step if you use basic authentication. The next steps are performed in SAP SuccessFactors Admin Center and are relevant for certificate-based authentication only.

   b. Login to SAP SuccessFactors and go to *Admin Center*. Follow the procedure described in Upgrade to X.509 Certificate-Based Authentication for Incoming Calls.

      Make sure you select *Identity Provisioning Service* in the *Integration Name* field.
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*

URL	Specify the URL to your SAP SuccessFactors API.
	
	For example:
	• For version 1:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com/odata/v2`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com/odata/v2`**
	• For version 2:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com`**
	
	To see the list of all SAP SuccessFactors data centers, see: SAP SuccessFactors API Reference Guide (OData V2): List of SAP SuccessFactors API Servers and System for Cross-domain Identity Management for Workforce in SuccessFactors

`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*

Property Name	Description & Value
(Optional) `sf.api.version`	Handles the version of the API which is consumed by the SAP SuccessFactors system. **Possible values:** • *1* - Indicates that SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. • *2* - Indicates that SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used. Default value: *1*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *userID* of your SAP SuccessFactors technical user in the following format: **<user_ID>@<company_ID>**
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the password for your SAP SuccessFactors technical user.
`sf.company.id`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the Company ID of your SAP SuccessFactors system. The Company ID is a short string of characters that identifies each SAP SuccessFactors system. It is like a username for your organization. All users of the same system share the same Company ID.
`sf.user.attributes`	Default property. It's a string representing a comma-separated list of user attributes by which the Identity Provisioning service retrieves the users that have to be updated in SAP SuccessFactors during the writing process. You can leave the default property value (all listed attributes), or leave only some of them. → Remember Always make sure that attribute `lastModifiedDateTime` is in the list. If you don't specify it, the provisioning to SAP SuccessFactors will fail. **Connector version**: SAP SuccessFactors version 1

Property Name	Description & Value
`sf.user.unique.attribute`	When the Identity Provisioning attempts to provision a user for the first time, it may detect that such a user already exists on the target system. Thus, the service needs to retrieve the *entityId* of the existing user via filtering by user unique attribute(s). This property defines by which unique attribute(s) the existing user to be searched (resolved). **If the service finds such a user on the target system via this filter, then the conflicting user will overwrite the existing one.** If the service does not find such a user, the creation will fail. According to your use case and system type, choose how to set up this property: • Default behavior: This property is missing during system creation. Its default value is *userName*. That means, if the service finds an existing user by a *userName*, it updates this user with the data of the conflicting one. If a user with such a *userName* is not found, the creation of the conflicting user fails. • Value = *emails[0].value*. If the service finds an existing user with such *email*, it updates this user with the data of the conflicting one. If a user with such *email* is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. • Value = *userName,emails[0].value*. If the service finds an existing user with both these *userName* and *email*, it updates this user with the data of the conflicting one. If such a user is not found, that means the conflict is due to another reason, so the creation of the conflicting user fails. **Possible values:** • *userName* • *emails[0].value* • *userName,emails[0].value* • *externalId*, or another SCIM attribute, or a conjunction of SCIM attributes Default value: *userName* **Connector version**: SAP SuccessFactors version 2
(Optional) `sf.user.attributes.expand`	This property writes additional user data related to *complex attributes*, which are specified in `sf.user.attributes`. Default value: *personKeyNav* **Connector version**: SAP SuccessFactors version 1

Property Name	Description & Value
`sf.group.unique.attribute`	If the service tries to create a group that already exists in the target system, the creation will fail. In this case, the existing group only needs to be updated. This group can be found via search, based on an attribute (default or specific). To make the search filter by a specific attribute, specify this attribute as a value for the `sf.group.unique.attribute` property. If the property is not specified, the search is done by the default attribute: *displayName* **Connector version**: SAP SuccessFactors version 2
(Optional) `sf.group.prefix`	This property distinguishes SAP SuccessFactors groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **SF_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **SF_** prefix in their display name will be provisioned to SAP SuccessFactors. Groups without this prefix in the display name won't be provisioned. If the property is not set, the SAP SuccessFactors groups will be read and provisioned to the target system with their actual display names. **Connector version**: SAP SuccessFactors version 2

Property Name	Description & Value
(Optional) `sf.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. This means, for example, that if a user attribute is modified, only this change will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false* **Connector version**: SAP SuccessFactors version 2
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination (configuration):

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://apitest.successfactors.com/odata/v2*

`User`=*sfsf_admin@mycompany.com*

`Password`=**********

`sf.user.attributes`=*userId,username,addressLine1,jobTitle,lastName,country,email,location,firstName,lastModifiedDateTime,personKeyNav,manager/username*

`sf.user.attributes.expand`=*personKeyNav,manager*

---

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   When you configure SAP SuccessFactors as a target system, the Identity Provisioning service will read all user attributes from the selected source system and write them as user records in SAP SuccessFactors. Groups can be only updated if such already exist in SAP SuccessFactors.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors. For more information, see:

   Manage Transformations [page 2439]

   SAP SuccessFactors HCM Suite OData API

   SAP SuccessFactors Workforce SCIM API

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation for SAP SuccessFactors HCM Suite OData API version 1:

   Code Syntax

```
{
    "user": {
        "skipOperations": [
            "delete"
        ],
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.userId"
            },
```

```
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userId",
                "scope": "createEntity"
            },
            {
                "constant": "t",
                "targetPath": "$.status"
            },
            {
                "condition": "$.active == false",
                "constant": "f",
                "targetPath": "$.status"
            },
            {
                "sourcePath": "$.userName",
                "optional": true,
                "targetPath": "$.username"
            },
            {
                "sourcePath": "$.name.familyName",
                "optional": true,
                "targetPath": "$.lastName"
            },
            {
                "sourcePath": "$.name.givenName",
                "optional": true,
                "targetPath": "$.firstName"
            },
            {
                "sourcePath": "$.name.honorificPrefix",
                "optional": true,
                "targetPath": "$.salutation"
            },
            {
                "sourcePath": "$.name.honorificSuffix",
                "optional": true,
                "targetPath": "$.suffix"
            },
            {
                "sourcePath": "$.emails[0].value",

                    }
                ]
            },
            {
                "sourcePath": "$.addresses[0].locality",
                "optional": true,
                "targetPath": "$.city"
            },
            {
                "condition": "$.addresses[?(@.primary == true)].locality !
= []",
                "sourcePath": "$.addresses[?(@.primary == true)].locality",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.city",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "sourcePath": "$.addresses[0].formatted",
                "optional": true,
                "targetPath": "$.addressLine1"
            },
            {
                "sourcePath": "$.addresses[1].formatted",
                "optional": true,
                "targetPath": "$.addressLine2"
            },
            {
                "sourcePath": "$.addresses[2].formatted",
                "optional": true,
                "targetPath": "$.addressLine3"
            },
            {
                "condition": "$.phoneNumbers[?(@.type == 'work')].value !=
[]",
                "sourcePath": "$.phoneNumbers[?(@.type == 'work')].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.businessPhone",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
```

```
                "condition": "$.phoneNumbers[?(@.type == 'fax')].value !=
[]",
                "sourcePath": "$.phoneNumbers[?(@.type == 'fax')].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.fax",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "condition": "$.phoneNumbers[?(@.type == 'mobile')].value !
= []",
                "sourcePath": "$.phoneNumbers[?(@.type ==
'mobile')].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.cellPhone",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "condition": "$.phoneNumbers[?(@.type == 'home')].value !=
[]",
                "sourcePath": "$.phoneNumbers[?(@.type == 'home')].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.homePhone",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['employeeNumber']",
                "optional": true,
                "targetPath": "$.empId"
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['division']",
                "optional": true,
                "targetPath": "$.division"
            },
            {
                "sourcePath":
"$['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']
['department']",
                "optional": true,
                "targetPath": "$.department"
            }
        ]
    },
// By default, the group mapping is inactive (ignored) but groups are
supported.
```

```
// To start provisioning groups, either delete the statement "ignore":
true, or set its value to false.
    "group": {
        "ignore": true,
        "skipOperations": [
            "delete"
        ],
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.groupID"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.groupName"
            },
            {
                "constant": "DynamicGroup",
                "targetPath": "$.__metadata.uri"
            },
            {
                "constant": "permission",
                "targetPath": "$.groupType"
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "type": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

Default transformation for SCIM API version 2:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant": [
          "urn:ietf:params:scim:schemas:extension:successfactors:2.0:User",
          "urn:ietf:params:scim:schemas:core:2.0:User",
          "urn:ietf:params:scim:schemas:extension:sap:2.0:User",
          "urn:ietf:params:scim:schemas:extension:enterprise:2.0:User"
        ],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
```

```
        "sourcePath": "$.userType",
        "targetPath": "$.userType"
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true
      },
      {
        "sourcePath": "$.emails",

        "optional": true,
        "targetPath": "$.groups[?(@.value)]",
        "functions": [
          {
            "entityType": "group",
            "function": "resolveEntityIds"
          }
        ]
      }
    ]
  },
  "group": {
    "condition": "('%sf.group.prefix%' === 'null') || ($.displayName =~ /
%sf.group.prefix%.*/)",
    "skipOperations": [
      "delete"
    ],
    "mappings": [
      {
        "targetPath": "$.id",
        "sourceVariable": "entityIdTargetSystem"
      },
      {
        "sourcePath": "$.displayName",
```

```
        "targetPath": "$.displayName",
        "scope": "createEntity",
        "functions": [
          {
            "condition": "('%sf.group.prefix%' !== 'null') && (@ =~ /
%sf.group.prefix%.*/)",
            "function": "replaceFirstString",
            "regex": "%sf.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "targetPath": "$.members",
        "type": "remove"
      },
      {
        "sourcePath": "$.members[*].value",
        "targetPath": "$.members[?(@.value)]",
        "optional": true,
        "preserveArrayWithSingleElement": true,
        "functions": [
          {
            "type": "resolveEntityIds"
          }
        ]
      }
    ]
  }
}
```

6. Now, add a source system to read users from it. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.43 SAP SuccessFactors Employee Central Payroll

Follow this procedure to set up SAP SuccessFactors Employee Central Payroll as a target system.

Context

SAP SuccessFactors Employee Central Payroll is a cloud product for payroll processing. It's a service offering where SAP SuccessFactors Employee Central is used for maintenance of core HR master data and an SAP HCM Payroll system hosted in an SAP or Hyperscaler data center is used for payroll.

You can use Identity Provisioning to configure SAP SuccessFactors Employee Central Payroll as a target system where you provision users and groups from source systems.

> **Note**
>
> When executing a provisioning job, by default users with no `name.familyName` attribute will be skipped, and thus, won't be created in SAP SuccessFactors Employee Central Payroll.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP SuccessFactors Employee Central Payroll* as a target system. For more information, see Add New Systems [page 2415].
3. Set up the communication between Identity Provisioning and SAP SuccessFactors Employee Central Payroll and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP SuccessFactors Employee Central Payroll target system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next step is performed in SAP SuccessFactors Employee Central Payroll backend system and is relevant for both basic and certificate-based authentication.

   b. For certificate-based authentication, import the certificate generated in the Identity Provisioning UI in your SAP SuccessFactors Employee Central Payroll system, as described in Prerequisite: Finding the Access URL → step 5.

      For basic authentication, provide *User* and *Password*, as described in Prerequisite: Finding the Access URL → step 5.

c. Save your changes.

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP SuccessFactors Employee Central Payroll system. For more information, see Prerequisite: Finding the Access URL → step 8.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication* For more information, see Prerequisite: Finding the Access URL → step 5.
`User`	Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`ecp.sap-client`	Enter the SAP client number (a three-digit number) of your SAP SuccessFactors Employee Central Payroll system. For example: **`102`**
(Optional) `ecp.user.unique.attribute`	If Identity Provisioning tries to provision a user that already exists in the target system (a conflicting user), this property defines the unique attributes by which the existing user will be searched and resolved. Possible values: *userName* (default value)
(Optional) `ecp.group.unique.attribute`	If the Identity Provisioning tries to create a group that already exists in the target system (a conflicting group), this property defines the unique attributes by which the existing group will be searched and resolved. **Possible values:** *displayName* (default value)

Property Name	Value
(Optional) `ecp.group.prefix`	This property distinguishes SAP SuccessFactors Employee Central Payroll groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **ECP_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **ECP_** prefix in their display name will be provisioned to SAP SuccessFactors Employee Central Payroll. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be be provisioned to SAP SuccessFactors Employee Central Payroll.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Employee Central Payroll* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Employee Central Payroll system. For more information, see:

   Manage Transformations [page 2439]

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP SuccessFactors Employee Central Payroll entity.

   Default transformation:

Code Syntax

```
{
    "user": {
        "condition": "($.name.familyName EMPTY false) &&
(('%ecp.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%ecp.group.prefix%.*/)] empty false))",
        "mappings": [
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:User",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:User"
                ],
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.schemas"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName"
            },
            {
                "sourcePath": "$.name.middleName",
                "targetPath": "$.name.middleName",
                "optional": true
            },
            {
                "sourcePath": "$.nickName",
                "targetPath": "$.nickName",
                "optional": true
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true
            },
            {
                "sourcePath": "$.phoneNumbers",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.phoneNumbers",
                "optional": true
            },
            {
                "sourcePath": "$.emails",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.emails",
                "optional": true
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true
            },
            {
                "sourcePath": "$.groups",
```

```
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.groups",
                "optional": true
            }
        ]
    },
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
ecp.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
ecp.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": [
                    "urn:ietf:params:scim:schemas:core:2.0:Group",
                    "urn:ietf:params:scim:schemas:extension:sap:2.0:Group"
                ],
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition":
"isAttributeWithOptionalPrefix($.displayName, ecp.group.prefix)",
                        "function": "replaceFirstString",
                        "regex": "%ecp.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"

                ]
            },
            {
                "constant": "User",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[*].type",
                "scope": "createEntity"
            }
        ]
    }
}
```

6. Add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

Identity Provisioning for Employee Central Payroll

1.6.2.44 SAP SuccessFactors Incentive Management

Follow this procedure to set up a target connector for SAP SuccessFactors Incentive Management, formerly known as SAP Commissions.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the API of SAP SuccessFactors Incentive Management for creating or updating users and user assignments.

Context

After fulfilling the prerequisites, follow the procedure below to add a target system for SAP SuccessFactors Incentive Management to write users to it. This target system consumes SCIM 2.0 API provided by SAP SuccessFactors Incentive Management.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP SuccessFactors Incentive Management* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP SuccessFactors Incentive Management SCIM API portal.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP SuccessFactors Incentive Management system.
`Password`	(Credential) Enter the password for your SAP SuccessFactors Incentive Management user.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://mycommissions.callidus.run/CallidusPortal*

`User`=*MyCommissionsUser*

`Password`=**********

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Incentive Management* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Incentive Management. For more information, see:

Manage Transformations [page 2439]

SAP SuccessFactors Incentive Management REST API

Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. If the entity has more than one e-mail addresses, only one of them is used. It is either the e-mail set as primary in the source system, or if no primary e-mail is set, the one that comes first is used.

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.userName",
                "targetPath": "$.id",
                "targetVariable": "entityIdTargetSystem"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.externalId",
                "optional": true,
                "defaultValue": ""
            },
            {
                "sourcePath": "$.name.givenName",
                "targetPath": "$.name.givenName",
                "optional": true,
                "defaultValue": ""
            },
            {
                "sourcePath": "$.name.familyName",
                "targetPath": "$.name.familyName",
                "optional": true,
                "defaultValue": ""
            },
            {
                "sourcePath": "$.active",
                "targetPath": "$.active",
                "optional": true
            },
// For each user in SAP SuccessFactors Incentive Management, only one
email is written. It can be either the primary email, or the first email
from the "emails[]" list.
            {
                "sourcePath": "$.emails[0].value",
                "targetPath": "$.emails[0].value",
                "optional": true,
                "defaultValue": ""
            },
            {
                "condition": "$.emails[?(@.primary == true)].value != []",
                "sourcePath": "$.emails[?(@.primary == true)].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
```

```
                "targetPath": "$.emails[0].value",
                "functions": [
                    {
                        "function": "elementAt",
                        "index": 0
                    }
                ]
            },
            {
                "constant": "",
                "targetPath": "$.groups[0].value"
            },
            {
                "condition": "$.groups EMPTY false",
                "sourcePath": "$.groups",
                "preserveArrayWithSingleElement": true,
                "targetPath": "$.groups",
                "optional": true
            },
            {
                "sourcePath": "$.locale",
                "targetPath": "$.locale",
                "optional": true,
                "defaultValue": ""
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "optional": true,
                "defaultValue": ""
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            }
        ]
    }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

SAP SuccessFactors Incentive Management: Integration with SAP IdP

1.6.2.45 SAP SuccessFactors Learning

Follow this procedure to set up SAP SuccessFactors Learning as a target system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the SAP SuccessFactors Learning API for provisioning user information.

Context

SAP SuccessFactors Learning is a learning solution which helps organizations to improve employee skills and talent management, align learning outcomes with performance goals, boost compliance, and train external audiences.

You can use the Identity Provisioning user interface (UI) to configure SAP SuccessFactors Learning as a target system where you can provision users from source systems.

> ⚠ Restriction
>
> Provisioning **groups** is not supported.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SAP SuccessFactors Learning* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
Type	Enter: *HTTP*
URL	Specify the URL to the API of your SAP SuccessFactors Learning system. It follows the pattern: `https://<root URL>/learning/public-api/rest/admin/Integration.svc/ias`

Property Name	Value
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user ID for SAP SuccessFactors Learning.
`Password`	(Credential) Enter the password for the SAP SuccessFactors Learning technical user. For more information, see Learning Technical User.
(Optional) `lms.user.unique.attribute`	This property appears by default when the system is created, and its value is set to *userName*. It defines by which unique attribute(s) an existing user to be resolved in the event of conflicting users.
(Optional) `lms.support.patch.operation`	Controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. • If set to *false*, PUT operations are used to update users in the target system.
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Learning* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Learning system. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP SuccessFactors Learning

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target SAP SuccessFactors Learning entity.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "constant":
["urn:ietf:params:scim:schemas:core:2.0:User","urn:sap:cloud:scim:schemas:e
xtension:custom:2.0:User","urn:ietf:params:scim:schemas:extension:sap:2.0:U
ser"],
        "targetPath": "$.schemas"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName",
        "optional": true
      },
      {
        "sourcePath": "$.externalId",
        "targetPath": "$.externalId",
        "optional": true
      },
      {
        "sourcePath": "$.locale",
        "targetPath": "$.locale",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['userUuid']",
        "optional": true
      },
      {
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['siteID']",
        "targetPath": "$
['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']['siteID']",
        "optional": true
      },
      {
        "sourcePath": "$.custom-column-path-1",

"targetPath": "$['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']
['customColumns']['110']",
        "optional": true
      },
      {
        "sourcePath": "$.custom-column-path-2",

"targetPath": "$['urn:sap:cloud:scim:schemas:extension:custom:2.0:User']
['customColumns']['120']",
        "optional": true
      },
      {
```

```
        "condition": "$.emails[?(@.primary== true)] empty false",
        "sourcePath": "$.emails[?(@.primary== true)].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.emails[?(@.value)]"
      },
      {
        "condition": "$.emails[?(@.primary== true)] empty true",
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.emails[0].value",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.middleName",
        "targetPath": "$.name.middleName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName"
      },
      {
        "condition": "$.phoneNumbers[?(@.primary== true)] empty false",
        "sourcePath": "$.phoneNumbers[?(@.primary== true)].value",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.phoneNumbers[?(@.value)]"
      },
      {
        "condition": "$.phoneNumbers[?(@.primary== true)] empty true",
        "sourcePath": "$.phoneNumbers[0].value",
        "targetPath": "$.phoneNumbers[0].value",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active"
      }
    ]
  }
}
```

5. Add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.46 Sales Cloud – Analytics & AI

Follow this procedure to set up a target connector for Sales Cloud – Analytics & AI.

Prerequisites

You have technical user credentials for an Sales Cloud – Analytics & AI (in short, *SCAAI*) system with read and write access permissions.

Context

After fulfilling the prerequisites, follow the procedure to add a target system for Sales Cloud – Analytics & AI to write users and user assignments to groups. This target system consumes SCIM 2.0 API provided by SCAAI.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Sales Cloud – Analytics & AI* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API portal of your SCAAI system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SCAAI system.
`Password`	(Credential) Enter the password for your SCAAI user.
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your SCAAI administrator.

Property Name	Value
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*http://myscaai:8080/scim_services*

`User`=*MySCAAIUser*

`Password`=**********

`OAuth2TokenServiceURL`=*http://myscaai:8080/gateway_services/api/auth/ips/token*

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Sales Cloud – Analytics & AI* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Sales Cloud – Analytics & AI. For more information, see: Manage Transformations [page 2439]

   Mapping logic – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. The Identity Provisioning takes a user's original *userName* (from the source system) and assigns it as a user ID in the target SCAAI system. Analogically, the Identity Provisioning takes a group's original *displayName* and assigns it as a group ID in SCAAI.

   Default transformation:

   Code Syntax

   ```
   {
       "user": {
   ```

```
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.externalId"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:User",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            }
        ]
    },
    "group": {
        "skipOperations": [
            "delete"
        ],
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.externalId"
            },
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

If you want the users and groups in SCAAI to have the **same** IDs as the respective users and groups in the source system, modify the transformation mappings as follows:

- In the source system:

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.id",
```

```
                "correlationAttribute": true
            },
...
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.id"
            },
...
}
```

- In the SCAAI target system:

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.externalId"
            },
...
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.externalId"
            },
...
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.47 Cloud Foundry UAA Server

Follow this procedure to set up a Cloud Foundry UAA Server as a target system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

- You have technical user credentials for a Cloud Foundry system with write access permissions. In case OAuth is used for authentication, client ID and secret are required when creating a destination for access token retrieval. You need Cloud Foundry UAA version **4.2** or higher
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need to do this only if the Cloud Foundry UAA server is exposed in a private corporate network. For more information, see Cloud Connector.

Context

User Account and Authentication Service (UAA) is an OAuth2 server that you can use for centralized identity management. It owns the user accounts and authentication sources and supports standard protocols (such as *SAML*, *LDAP*, and *OpenID Connect*) to provide SSO and delegated authorization to Web applications. For more information, see Cloud Foundry: Overview .

> → Tip
>
> This connector is meant for writing users and groups in **general** Cloud Foundry systems (they could be non-SAP ones). If you want to trigger provisioning of entities to SAP Business Technology Platform Cloud Foundry applications, you'd better use SAP BTP XS Advanced UAA (Cloud Foundry) [page 1045] target system.

These target systems consume SCIM 1.1 API provided by Cloud Foundry UAA.

> → Remember
>
> You can write users and groups to Cloud Foundry on **application** level only. You cannot provision or manage them on a *subaccount* level.

Follow the steps below to create Cloud Foundry UAA as a target system to provision users and groups.

Procedure

1. (Optional) If the Cloud Foundry UAA server is exposed in a private corporate network, add an access control system mapping in Cloud Connector. For more information, see Configure Access Control (HTTP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *Cloud Foundry UAA Server* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the Cloud Foundry UAA SCIM API. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	As you need to make OAuth authentication to the UAA system, enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`User`	Enter the OAuth client ID of the Cloud Foundry UAA technical user.
`Password`	(Credential) Enter the OAuth client secret of the technical user.
`uaa.origin`	Enter the location of your Cloud Foundry identity provider. If not sure about the value, ask your Cloud Foundry UAA administrator. The value of this property is a string, which will be used as the *origin* attribute in the system transformation.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://api.authentication.hana.ondemand.com
OAuth2TokenServiceURL=https://MyCFaccount.authentication.hana.ondemand.com/oauth/token
User=MyCFuser
Password=************
uaa.origin=my_UAA_location
```

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Cloud Foundry UAA Server* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   - **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the internal Cloud Foundry UAA representation to the target entity.
   - **User offboarding** – If a user has been deleted from the source system, this change is recognized, and the user is deleted from the Cloud Foundry UAA target system too.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Cloud Foundry UAA server. For more information, see:

   Manage Transformations [page 2439]

   Cloud Foundry UAA API: Users

   Cloud Foundry UAA API: Groups

   To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

   Default transformation:

   Code Syntax

```
{
  "user": {
    "condition": "($.emails.length() > 0) && (('%uaa.group.prefix%'
=== 'null') || ($.groups[?(@.display =~ /%uaa.group.prefix%.*/)] empty
false))",
    "mappings": [
      {
        "constant": "uaa-dummy-value",
        "targetPath": "$.id",
        "scope": "createEntity"
      },
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
```

```
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.userName"
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.name.givenName",
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.name.familyName",
        "optional": true
      },
      {
        "sourcePath": "$.active",
        "targetPath": "$.active",
        "optional": true
      },
      {
        "sourcePath": "$.verified",
        "targetPath": "$.verified",
        "optional": true
      },
      {
        "constant": "%uaa.origin%",
        "targetPath": "$.origin"
      },
      {
        "sourcePath": "$.phoneNumbers",
        "targetPath": "$.phoneNumbers",
        "preserveArrayWithSingleElement": true,
        "optional": true
      },
      {
        "sourcePath": "$.emails",
        "targetPath": "$.emails",
        "preserveArrayWithSingleElement": true
      },
      {
        "condition": "$.emails[?(@.primary == true)].value == []",
        "targetPath": "$.emails[0].primary",
        "constant": true
      },
      {
        "constant": "urn:scim:schemas:core:1.0",
        "targetPath": "$.schemas[0]"
      }
    ]
  },
  "group": {
    "condition": "isAttributeWithOptionalPrefix($.displayName,
uaa.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
uaa.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
    "mappings": [
      {
        "sourceVariable": "entityIdTargetSystem",
        "targetPath": "$.id"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName",
        "functions": [
          {
            "condition": "isAttributeWithMandatoryPrefix(@,
uaa.group.prefix)",
```

```
            "function": "replaceFirstString",
            "regex": "%uaa.group.prefix%",
            "replacement": ""
          }
        ]
      },
      {
        "sourcePath": "$.description",
        "targetPath": "$.description",
        "optional": true
      },
      {
        "sourcePath": "$.members",
        "targetPath": "$.members",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "functions": [
          {
            "function": "resolveEntityIds"
          },
          {
            "condition": "@.type EMPTY false",
            "function": "toUpperCaseString",
            "applyOnElements": true,
            "applyOnAttribute": "type",
            "locale": "en_EN"
          }
        ]
      },
      {
        "constant": "urn:scim:schemas:core:1.0",
        "targetPath": "$.schemas[0]"
      }
    ]
  }
}
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Cloud Foundry UAA: Groups

1.6.2.48 Google G Suite

Follow this procedure to set up Google G Suite as a target system.

Prerequisites

> **Restriction**
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

1. Sign in to the Google API console (https://console.developers.google.com) and create a project.
2. Enable the Admin SDK. To do this, go to *Dashboard* > *ENABLE API* > *Admin SDK* > *ENABLE*.
3. Create a service account for your project. We recommend that you select *Enable G Suite Domain-wide Delegation* during the creation. If you skip this option, you can set it later. For more information, see Creating a service account .
4. Then, in the Google admin console (https://admin.google.com), a user with **Super Admin** role can delegate domain-wide authority to your service account. This way, it will have access to the Google Admin SDK on behalf of your user. For more information, see Delegating domain-wide authority .

   > **Note**
   >
   > When specifying the scopes, the administrator has to enter the following:
   >
   > `https://www.googleapis.com/auth/admin.directory.user, https://www.googleapis.com/auth/admin.directory.group`

Context

A Google service account with delegated domain-wide authority is required for authentication and authorization of the Identity Provisioning service to G Suite domain. The authentication is based on OAuth 2.0 protocol with JSON Web Token (JWT). The private key for the signature is distributed by Google via one-time downloadable JSON data, which is accessible by the domain administrator. The private key is encoded in PKCS8 format and is in the *private_key* field of the JSON data. For more information, see JSON Web Token (JWT) .

- When using it as a source system, you can read both users and groups from Google G Suite and provision them to any target system you have added in the Identity Provisioning user interface.
- When using it as a target system, you can write both users and groups, read from any source system you have added in the Identity Provisioning user interface. Google G Suite can automatically create accounts for your users in the Google Cloud Datastore.

The Identity Provisioning service supports user and group operations based on the following Google Directory API. See the table below.

User Operations	Group Operations
Create a user	Create a group
Retrieve a user	Retrieve a group's properties
Update a user	Update a group's properties
Delete a user	Delete a group

> ⚠ Caution
>
> You can only provision users whose e-mails are from verified domains.

If you have successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure below.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Google G Suite* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
URL	Specify the service URL: **`https://www.googleapis.com/admin/directory`**
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication* The authentication type in use is actually **OAuth** with JWT. But for any provisioning system based on OAuth, **BasicAuthentication** is used along with the `OAuth2TokenServiceURL` additional property.
`User`	Enter the service account's ID. You can take it from the *"client_email"* field in the JSON data, downloaded during the setup of Google service account.

Property Name	Description & Value
`Password`	(Credential) Enter the service account's private key, which represents a long string in PKCS8 format. You can take it from the *"private key"* field in the JSON data, downloaded during the setup of Google service account.
`OAuth2TokenServiceURL`	To make OAuth authentication to the Google G Suite system, enter the URL to the access token provider service. For more information, see Using OAuth 2.0 to Access Google APIs .
`jwt.subject`	Enter the Google G Suite user on behalf of which the Google Directory API is called. This user has been assigned the role **User Management Admin**. This property corresponds to "sub" claim in JWT being generated during access token request: JWT: "sub" (Subject) Claim
(Optional) `jwt.scope`	Enter space-separated Google Directory API authorization scopes. For example: **`https://www.googleapis.com/auth/admin.directory.user`**
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary Configuration:

`ProxyType=`*Internet*

`Type=`*HTTP*

`Authentication=`*BasicAuthentication*

`URL=`*https://www.googleapis.com/admin/directory*

`User=`*1234567890-compute@developer.gserviceaccount.com*

`Password=`*-----BEGIN PRIVATE KEY-----\n123ABCDEFG123456789...*

... /123456789ABCDEFG123=\n-----END PRIVATE KEY-----\n

`OAuth2TokenServiceURL=`*https://www.googleapis.com/oauth2/v4/token*

`jwt.subject=`*john.smith@me123.accounts.ondemand.com*

`jwt.scope=`*https://www.googleapis.com/auth/admin.directory.user*

---

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Google G Suite* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   Transformation principles for the target system integration:

   - **Mapping logic** – The provisioning framework reads all attributes from the intermediate JSON data and tries to create consistent records in the Google G Suite target system, using all the available attributes accepted by the Google Directory API. When a required attribute is missing, the default transformation is designed with a condition that will exclude the inconsistent records. Bear in mind the following:
     - Make sure that the JSON data sent by the source system is consistent with the configuration template of the target. For example, if the source system contains mandatory fields and the target one does not support such kind of data, then the target system skips these fields. This may cause crucial data loss.
     - There is a special user status type called **suspended** (temporarily blocks a user without deleting any account data) for the Google directory accounts. When the status of the user account is changed to **suspended**, the Google Directory API will not accept any changes on the user attributes. Once the suspended user is restored by the administrator, all attribute changes pending for the account will be successfully provisioned with the next provisioning job.

     > ⚠ Caution
     >
     > An initial password setup is mandatory for all newly provisioned users. This is required by the Google G Suite API and must be provided when new accounts are created. The constant value that you see as configuration for the password attribute in the default transformation is generated by SAP. You have to change the constant value with another one, known only by the representatives of your company, before starting to use the Identity Provisioning service for creating users in your corporate Google G Suite system automatically.

   - **User off-boarding** – Identity Provisioning service is handling the deletion status of the users. When a user is deleted from the source system, this deletion will be enforced into the Google G Suite system as well.

You can change the default transformation mapping rules to reflect your current setup of entities in your Google G Suite. For more information, see:

Manage Transformations [page 2439]

Google Directory API: Users

Google Directory API: Groups

Default transformation:

Code Syntax

```
{
    "user": {
        "condition": "($.emails.length() > 0) && ($.name.familyName EMPTY
false)",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.name",
                "targetPath": "$.name"
            },
            {
                "sourcePath": "$.emails[0].value",
                "targetPath": "$.primaryEmail"
            },
            {
                "sourcePath": "$.phoneNumbers",
                "optional": true,
                "targetPath": "$.phones"
            },
            {
                "targetPath": "$.password",
                "scope": "createEntity",
                "functions": [
                    {
                        "type": "randomPassword",
                        "passwordLength": 16,
                        "minimumNumberOfLowercaseLetters": 1,
                        "minimumNumberOfUppercaseLetters": 1,
                        "minimumNumberOfDigits": 1,
                        "minimumNumberOfSpecialSymbols": 0
                    }
                ]
            },
            {
                "constant": "false",
                "targetPath": "$.suspended"
            },
            {
                "condition": "$.active == false",
                "constant": true,
                "targetPath": "$.suspended"
            },
            {
                "constant": "true",
                "targetPath": "$.changePasswordAtNextLogin"
            }
        ]
    },
    "group": {
        "ignore": true,
```

```
        "mappings": [
            {
                "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
                "targetPath": "$.schemas[0]"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.name"
            },
// Google G Suite requires a group e-mail. By default, the email attribute
is mapped to displayName. If group's Display Name does not contain an e-
mail,
// you can either map email to another attribute, or concatenate
displayName with your domain. To learn how, see the detailed explanation
and example below.

            {
                "sourcePath": "$.displayName",
                "targetPath": "$.email",
                "scope": "createEntity"
            },
            {
                "sourcePath": "$.members[?(@.type == 'User')].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.id)]",
                "functions": [
                    {
                        "entityType": "user",
                        "type": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

If the **displayName** attribute in the source system transformation does not provide group e-mails, you can modify the transformation the following ways:

- Map **email** to another attribute that contains a unique group e-mail.
- Concatenate the **displayName** attribute with your domain. For example:

Sample Code

```
        {
            "sourcePath": "$.displayName",
            "targetPath": "$.email",
            "scope": "createEntity",
            "functions": [
                {
                    "type": "concatString",
                    "suffix": "@test.myaccount.ondemand.com"
                }
            ]
        }
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.49 LDAP Server

Follow this procedure to set up LDAP Server as a target system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

> ⓘ Note
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo) or Cloud Connector (Cloud Foundry)
- **For tenants running on the infrastructure of SAP Cloud Identity Services**: You have a multi-environment subaccount in the Cloud Foundry region that maps the region of your Identity Authentication tenant and it is subscribed to the *Cloud Identity Services* application. For more information, see Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.
- You have the credentials of a technical user in the LDAP Server, which is used to call the LDAP Server API to write users and their attributes.

Context

You can use LDAP Server to write entities retrieved from a source system. This scenario supports writing **users** and **group assignments**.

There are two versions of the LDAP Server connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on May 25, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
- When the value is set to *2* – LDAP Server API version 2 is used.
  This version of the connector comes with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
  Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
  After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
  For more information on how to update to LDAP Server connector version 2, see Update Connector Version [page 2424].

Procedure

1. Add an access control system mapping for the **LDAP Server** in the Cloud Connector. This is needed to allow the Identity Provisioning service to access the LDAP server as a back-end system on the intranet. For more information, see Configure Access Control (LDAP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *LDAP Server* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify the destination URL. It must be in the following format: `ldap://<external_host>:<external_port>`
`ldap.proxyType`	Enter: *OnPremise*
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.user`	Enter the *distinguishedName* of the technical LDAP user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the LDAP technical user.

Property Name	Description & Value
`ldap.group.path`	Enter the complete path to the node containing the groups in the LDAP tree.
`ldap.user.path`	Enter the complete path to the users in the LDAP tree.
(Optional)`ldap.api.version`	Defines the version of LDAP Server API. **Possible values:** • **1** - Indicates that LDAP Server API version 1 is used. • **2** - Indicates that LDAP Server API version 2 is used. If the property is not defined - LDAP Server API version 1 is used.
`CloudConnectorLocationId`	Relevant when the proxy type is *OnPremise*. Use it only if your SAP Business Technology Platform account uses more than one Cloud Connector.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

> → Remember
>
> We strongly recommend that you enter different paths for LDAP users and groups. That means, the value of `ldap.user.path` should be different than the value of `ldap.group.path`.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

The LDAP Server target system is created by default with the properties listed below:

Default LDAP Properties

`ldap.user.attributes=`

`ldap.user.object.class=` **inetOrgPerson**

`ldap.group.object.class=` **groupOfNames**

`ldap.group.uniquename.attribute=` **cn**

`ldap.attribute.group.id=`**cn**

`ldap.attribute.group.member=` **member**

`ldap.attribute.group.object.class.required=`**cn**

`ldap.attribute.user.object.class.required=`**cn**

`ldap.attribute.user.id=` **uid**

`ldap.attribute.dn=`**distinguishedName**

`ldap.page.size=` **100**

`ldap.attribute.user.mail=` **mail**

`ldap.attribute.user.mobile=`**mobile**

`ldap.attribute.user.givenName=` **givenName**

`ldap.attribute.user.surname=` **sn**

`ldap.attribute.user.groups=` **memberOf**

`ldap.attribute.user.telephoneNumber=` **telephoneNumber**

> ### Note
>
> The **ldap.attribute.*** properties are used as parameterized properties in the default transformation. That is, if a property used in the transformation doesn't have a value, the provisioning job will fail when the transformation is loaded on runtime and the property value is substituted.
>
> Also, you can change a property and use a new one (with a new name). In this case, you must replace the old property with the new one at all corresponding places in the transformation.

> ### Note
>
> The `ldap.attribute.dn` property is auttomatically assigned and cannot be configured. It is used in the target system configuration for conflict resolution during user or group provisioning by the service.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *LDAP Server* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your LDAP server. For more information, see Manage Transformations [page 2439].

Currently, the default write transformations of the two connector versions have no differences, so there is no need to update them.

Before the write transformation (in the intermediate JSON data), the entity attributes are in SCIM format. After the transformation, the attributes in the LDAP Server are represented as arrays (single-element arrays, or multi-value arrays separated by comma (,)). For more information, see the official documentation for LDAP Server schema attributes in the **Related Information** section.

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "sourcePath": "$.userName",
        "targetPath": "$.%ldap.attribute.user.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.%ldap.attribute.user.object.class.required%[0]"
      },
      {
        "sourcePath": "$.emails[*].value",
        "optional": true,
        "targetPath": "$.%ldap.attribute.user.mail%"
      },
      {
        "sourcePath": "$.name.givenName",
        "optional": true,
        "targetPath": "$.%ldap.attribute.user.givenName%[0]"
      },
      {
        "sourcePath": "$.name.familyName",
        "optional": true,
        "targetPath": "$.%ldap.attribute.user.surname%[0]"
      },
      {
        "sourcePath": "$.phoneNumbers[*].value",
        "optional": true,
        "targetPath": "$.%ldap.attribute.user.mobile%"
      }
    ]
  },
  "group": {
    "ignore": true,
    "mappings": [
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.%ldap.attribute.group.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.%ldap.attribute.group.object.class.required%[0]"
```

```
      },
      {
        "constant": [],
        "targetPath": "$.member"
      },
      {
        "sourcePath": "$.members[*]",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetVariable": "membersVariable",
        "functions": [
          {
            "condition": "@.type != 'Group'",
            "entityType": "user",
            "type": "resolveEntityIds"
          },
          {
            "condition": "@.type == 'Group'",
            "entityType": "group",
            "type": "resolveEntityIds"
          },
          {
            "condition": "@.type != 'Group'",
            "function": "concatString",
            "applyOnElements": true,
            "applyOnAttribute": "value",
            "prefix": "%ldap.attribute.user.id%=",
            "suffix": ",%ldap.user.path%"
          },
          {
            "condition": "@.type == 'Group'",
            "function": "concatString",
            "applyOnElements": true,
            "applyOnAttribute": "value",
            "prefix": "%ldap.attribute.group.id%=",
            "suffix": ",%ldap.group.path%"
          }
        ]
      },
      {
        "sourceVariable": "membersVariable",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "targetPath": "$.member",
        "variablePath": "$[*].value"
      }
    ]
  }
}
```

Below is illustrated an example of how the data from LDAP Server looks like before and after executing a certain mapping from the write transformation:

Transformation Snippet (from the group mapping)	Intermediate JSON Data (before the transformation)	Target JSON Data (written in the LDAP Server)

Sample Code

```
"group": {
    ...
  {
    "sourcePath":
"$.members[*]",

"preserveArrayWithSi
ngleElement": true,
    "optional":
true,

"targetVariable":
"membersVariable",
    "functions": [
       {

"condition":
"@.type != 'Group'",

"entityType":
"user",
          "type":
"resolveEntityIds"
       },
       {

"condition":
"@.type == 'Group'",

"entityType":
"group",
          "type":
"resolveEntityIds"
       },
       {

"condition":
"@.type != 'Group'",
          "function":
"concatString",

"applyOnElements":
true,

"applyOnAttribute":
"value",
          "prefix":
"%ldap.attribute.use
r.id%=",
          "suffix":
",%ldap.user.path%"
       },
       {
```

Sample Code

```
...
"members":[
  {
    "value":
"SALES_US"
  },
  {
    "value":
"SALES_EU"
  },
  {
    "value":
"SALES_JA"
  }
]
…
```

Sample Code

```
...
"member": [
   "SALES_US",
   "SALES_EU",
   "SALES_JA"
]
…
```

Transformation Snippet (from the group mapping)	Intermediate JSON Data (before the transformation)	Target JSON Data (written in the LDAP Server)

```
"condition":
"@.type == 'Group'",
        "function":
"concatString",

"applyOnElements":
true,

"applyOnAttribute":
"value",
        "prefix":
"%ldap.attribute.gro
up.id%=",
        "suffix":
",%ldap.group.path%"
       }
    ]
   },
   {

"sourceVariable":
"membersVariable",

"preserveArrayWithSi
ngleElement": true,
    "optional":
true,
    "targetPath":
"$.member",
    "variablePath":
"$[*].value"
   }
  ]
 }
}
```

> **Note**
>
> By default, the **cn** attribute is used for writing the groups. An administrator can change this behavior by setting the following properties:
>
> - `ldap.group.uniquename.attribute` – the value can be either the CN or the whole DN (**distinguishedName**) of the group.
> - `ldap.attribute.group.id` – the value can be CN or another attribute to be used as a group ID instead (for example, **displayName** or **description**).
>
> For more information about these properties, see: List of Properties [page 80]

6. Now, add a source system to read users and groups from it. Choose from: Source Systems [page 585]

Setting Timeout for Ldap Operations
Connection Pooling Configuration

1.6.2.50 Microsoft Active Directory

Follow this procedure to set up Microsoft Active Directory as a target system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

> ⓘ Note
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have the credentials of a technical user in the Microsoft Active Directory, which is used to call the Microsoft Active Directory API to write users, groups and their attributes.

Context

You can configure Microsoft Active Directory as a target system to provision identities. Currently, you can provision users, groups and group assignments.

There are two versions of the Microsoft AD connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on June 19, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
  In this version, the `group members` attribute mapping in the proxy read transformation does not include `type` sub-attribute. In this case, all members are considered of type `User`, which is the sub-attribute fallback value. As a consequence, if the external system includes nested groups, they will not be handled properly.
- When the value is set to *2* – LDAP Server API version 2 is used.

This version of the connector is with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
In this version, the `group members` attribute mapping in the proxy read transformation is enhanced with `type` sub-attribute. The sub-attribute has two possible values – `User` and `Group`. This allows you to read and preserve nested groups.
For more information on how to update to Microsoft Active Directory version 2, see Update Connector Version [page 2424].

Procedure

1. Add an access control system mapping for the **Microsoft Active Directory** in the Cloud Connector. This is needed to allow the Identity Provisioning service to access Microsoft AD as a back-end system on the intranet. For more information, see Configure Access Control (LDAP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *Microsoft Active Directory* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify a destination URL. It must be in the following format: `ldap://<ext_host>:<ext_port>`
`ldap.proxyType`	Enter: *OnPremise*
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.user`	Enter the *distinguishedName* or the *userPrincipalName* of the Microsoft AD technical user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the Microsoft AD technical user.
`ldap.attribute.user.id`	Default property, which denotes the ID of a user. By default, it's set to: *cn*

Property Name	Description & Value
`ldap.attribute.group.id`	Default property, which denotes the ID of a group. By default, it's set to: *cn*
`ldap.attribute.dn`	Default property, which denotes the distinguished name of a user or a group. The distinguished name is auttomatically assigned and cannot be configured. It is used in the target system configuration for conflict resolution during user or group provisioning by the service. Only possible value: *distinguishedName*
`ldap.group.path`	Enter the complete path to the node containing the groups in Microsoft Active Directory.
`ldap.user.path`	Enter the complete path to the users in Microsoft Active Directory.
`CloudConnectorLocationId`	Relevant when the proxy type is *OnPremise*. Use it only if your SAP Business Technology Platform account uses more than one Cloud Connector.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Example for a destination or a set of properties:

```
Type=LDAP
Name=MyADDestination
ldap.user=john.smith@some.dummy.domain.com
ldap.password=********
ldap.attribute.user.id=cn
ldap.attribute.group.id=cn
ldap.attribute.dn=distinguishedName
ldap.url=ldap://abcd:123
ldap.proxyType=OnPremise
ldap.authentication=BasicAuthentication
ldap.group.path=OU=Groups,OU=IAS,DC=global,DC=corp,DC=mycompany
ldap.user.path=OU=Users,OU=IAS,DC=global,DC=corp,DC=mycompany
```

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Active Directory* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   In the intermediate JSON data, the Microsoft Active Directory attributes are in SCIM format. After the write transformation, the attributes are represented as arrays – single-element arrays, or multi-value arrays separated by comma (,). For more information about Microsoft AD schema attributes, see the **Related Information** section.

   Currently, the default write transformations of the two connector versions have no differences, so there is no need to update them.

   You can change the default transformation mapping rules to reflect your current setup of entities in Microsoft AD. For more information, see:

   Manage Transformations [page 2439]

   > ### Note
   >
   > You can provision users with *unicodePwd* attribute to Microsoft Active Directory target systems although it is not included in the default write transformation. This attribute specifies the password of the user in Windows NT operating system one-way format (OWF).

To provision the user password in encrypted format, proceed as follows:

1. Add the unicodePwd attribute mapping in the write transformation. For example:

   Code Syntax

   ```
   {
   "sourcePath": "$.Source_System_Attribute",
   "targetPath": "$.unicodePwd"
   }
   ```

2. Follow the requirements for provisioning users with *unicodePwd*, as described in unicodePwd

Default transformation:

Code Syntax

```
{
  "user": {
    "mappings": [
      {
        "condition": "('%ldap.attribute.user.id%' !=
'%ldap.attribute.dn%')",
        "sourcePath": "$.userName",
        "targetPath": "$.%ldap.attribute.user.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
// If a user is not a direct member of the configured user base
path, then its distinguishedName is configured to be equal to CN =
<userName>,<nested_path>,<base_path>,
// where <nested_path> is read from "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:User']['nestedPath']"
      {
        "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:User']['nestedPath']",
        "optional": true,
        "targetVariable": "nestedPathVariable",
        "defaultValue": "",
        "scope": "createEntity"
      },
      {
        "condition": "('%ldap.attribute.user.id%' ==
'%ldap.attribute.dn%')",
        "sourcePath": "$.userName",
        "functions": [
          {
            "function": "concatString",
            "prefix": "CN="
          },
          {
            "condition": "('${nestedPathVariable}' != '')",
            "function": "concatString",
            "suffix": ","
          },
          {
            "condition": "('${nestedPathVariable}' != '')",
            "function": "concatString",
            "suffix": "${nestedPathVariable}"
          },
          {
            "function": "concatString",
```

```
            "suffix": ",%ldap.user.path%"
          }
        ],
        "targetPath": "$.%ldap.attribute.user.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.cn[0]",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.userName",
        "targetPath": "$.sAMAccountName[0]"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.displayName[0]",
        "defaultValue": [],
        "optional": true
      },
      {
        "sourcePath": "$.emails[0].value",
        "targetPath": "$.mail[0]",
        "defaultValue": [],
        "optional": true
      },
      {
        "sourcePath": "$.name.givenName",
        "targetPath": "$.givenName[0]",
        "defaultValue": [],
        "optional": true
      },
      {
        "sourcePath": "$.name.familyName",
        "targetPath": "$.sn[0]",
        "defaultValue": [],
        "optional": true
      }
    ]
  },
  "group": {
    "ignore": true,
    "mappings": [
      {
        "condition": "('%ldap.attribute.group.id%' !=
'%ldap.attribute.dn%')",
        "sourcePath": "$.displayName",
        "targetPath": "$.%ldap.attribute.group.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
// If a group is not a direct member of the configured group base
path, then its distinguishedName is configured to be equal to CN =
<displayName>,<nested_path>,<base_path>,
// where <nested_path> is read from "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:Group']['nestedPath']"
      {
        "condition": "('%ldap.attribute.group.id%' ==
'%ldap.attribute.dn%')",
        "sourcePath": "$
['urn:sap:cloud:scim:schemas:extension:ad:2.0:Group']['nestedPath']",
        "optional": true,
        "targetVariable": "nestedPathVariable",
        "defaultValue": "",
        "scope": "createEntity"
      },
```

```
      {
        "condition": "('%ldap.attribute.group.id%' ==
'%ldap.attribute.dn%')",
        "sourcePath": "$.displayName",
        "functions": [
          {
            "function": "concatString",
            "prefix": "CN="
          },
          {
            "condition": "('${nestedPathVariable}' != '')",
            "function": "concatString",
            "suffix": ","
          },
          {
            "condition": "('${nestedPathVariable}' != '')",
            "function": "concatString",
            "suffix": "${nestedPathVariable}"
          },
          {
            "function": "concatString",
            "suffix": ",%ldap.group.path%"
          }
        ],
        "targetPath": "$.%ldap.attribute.group.id%[0]",
        "targetVariable": "entityIdTargetSystem",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.cn[0]",
        "scope": "createEntity"
      },
      {
        "sourcePath": "$.displayName",
        "targetPath": "$.sAMAccountName[0]"
      },
      {
        "sourcePath": "$.members[*]",
        "targetVariable": "membersVariable",
        "preserveArrayWithSingleElement": true,
        "optional": true,
        "functions": [
          {
            "condition": "@.type != 'Group'",
            "entityType": "user",
            "applyOnElements": true,
            "type": "resolveEntityIds"
          },
          {
            "condition": "@.type == 'Group'",
            "entityType": "group",
            "applyOnElements": true,
            "type": "resolveEntityIds"
          },
          {
            "condition": "(@.type != 'Group') &&
('%ldap.attribute.user.id%' != '%ldap.attribute.dn%')",
            "function": "concatString",
            "applyOnElements": true,
            "applyOnAttribute": "value",
            "prefix": "%ldap.attribute.user.id%=",
            "suffix": ",%ldap.user.path%"
          },
          {
            "condition": "(@.type == 'Group') &&
('%ldap.attribute.group.id%' != '%ldap.attribute.dn%')",
            "function": "concatString",
```

```
            "applyOnElements": true,
            "applyOnAttribute": "value",
            "prefix": "%ldap.attribute.group.id%=",
            "suffix": ",%ldap.group.path%"
          }
        ]
      },
      {
        "sourceVariable": "membersVariable",
        "variablePath": "$[*].value",
        "targetPath": "$.member",
        "defaultValue": [],
        "preserveArrayWithSingleElement": true,
        "optional": true
      }
    ]
  }
}
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> **Note**
>
> Identity Provisioning escapes the following special characters: comma (,), plus (+) and semicolon (;) in the CN component of the distinguished name (DN). This means that, if a user attribute in the source system contains a special character (`John, Smith`), and this attribute is mapped to the CN in Microsoft AD target system, the comma will be escaped in the DN.
>
> The following special characters cannot be escaped and result in an error: equal sign (=), less than symbol (<), greater than symbol (>), hash sign (#) and backslash (\).

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.51 Microsoft Entra ID

Follow this procedure to set up Microsoft Entra ID (formerly known as Microsoft Azure Active Directory) as a target system.

Prerequisites

> **⚠ Restriction**
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

- You've logged on to Microsoft Azure Portal, with credentials for a user with directory role **Global administrator**. For more information, see Microsoft Entra built-in roles .
- In *Azure Active Directory* > *App registrations*, you've registered an application with a secret key and permissions for Microsoft Graph API. These permissions must be consented by an administrator. For more information, see Microsoft Graph permissions reference .
- (Relevant to target systems) Your registered application is assigned the **User Account Administrator** role. This role allows you to deprovision users. For more information, see Add-MsolRoleMember .

  > **ⓘ Note**
  >
  > If this role isn't assigned, you can only disable users. To do that, set the `accountEnabled` property to **false**. For more information, see MS Graph: user resource type

Permissions

Assign the following permissions to your application, according to your scenario. Also, the permissions have to be of type *Application*.

- Users – *User.ReadWrite.All*, *Directory.AccessAsUser.All*
- Groups – *Group.ReadWrite.All*

For more information, see MS Graph: Users and MS Graph: Groups

Context

When using it as a target system, you can write both users and groups, read from any source system you've added in the Identity Provisioning user interface. The Microsoft Entra ID target systems use Microsoft Graph API. For more information, see Microsoft Graph .

If you've successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Microsoft Entra ID* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **https://graph.microsoft.com**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the application ID registered in your Microsoft Entra ID subscription (see the **Prerequisites** section).
`Password`	(Credential) Enter the secret key associated to your app registration.
`aad.domain.name`	Enter one of the verified domain names from the corresponding Microsoft Entra ID tenant. On this domain, you perform the provisioning operations. For more information, see Managing custom domain names in your Microsoft Entra ID .
`OAuth2TokenServiceURL`	Enter: **https://login.microsoftonline.com/<your_domain>/oauth2/token**, where `<your_domain>` is the domain name you have set in the **`aad.domain.name`** property.
(Optional) `aad.oauth2.resource.name`	Specifies the OAuth2 resource name for Microsoft Graph API. Enter: **https://graph.microsoft.com** You can change the Microsoft Graph endpoint to match your organization's cloud environment. For more information, see Microsoft Graph national cloud deployments.
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Deprecated) `oauth.resource.name`	Enter: **https://graph.microsoft.com** **Note** The **oauth.resource.name** property has been deprecated, as it is no longer needed by the MS Entra ID connector. Use the **aad.oauth2.resource.name** property instead.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Entra ID* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in Microsoft Entra ID. For more information, see:

   Manage Transformations [page 2439]

   MS Graph: Users

   MS Graph: Groups

   Default transformation:

   Code Syntax

```
{

                        "minimumNumberOfLowercaseLetters": 1,
                        "minimumNumberOfUppercaseLetters": 1,
                        "minimumNumberOfDigits": 1,
                        "minimumNumberOfSpecialSymbols": 0
                    }
                ]
            },
            {
                "constant": false,
```

```
                "targetPath":
"$.passwordProfile.forceChangePasswordNextSignIn",
                "scope": "createEntity"
            }
        ]
    },
    "group": {
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "sourcePath": "$.displayName",
                "optional": true,
                "targetPath": "$.displayName"
            },
            {
                "sourcePath": "$.description",
                "optional": true,
                "targetPath": "$.description"
            },
            {
                "sourcePath": "$.allowExternalSenders",
                "optional": true,
                "targetPath": "$.allowExternalSenders"
            },
            {
                "sourcePath": "$.autoSubscribeNewMembers",
                "optional": true,
                "targetPath": "$.autoSubscribeNewMembers"
            },
            {
                "sourcePath": "$.isSubscribedByMail",
                "optional": true,
                "targetPath": "$.isSubscribedByMail"
            },
            {
                "sourcePath": "$.visibility",
                "optional": true,
                "targetPath": "$.visibility"
            },
            {
                "sourcePath": "$.securityEnabled",
                "optional": true,
                "targetPath": "$.securityEnabled"
            },
            {
                "sourcePath": "$.mailEnabled",
                "optional": true,
                "targetPath": "$.mailEnabled"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "scope": "createEntity"
            },
            {
                "sourcePath": "$.externalId",
                "targetPath": "$.mailNickname",
                "scope": "createEntity"
            },
            {
                "constant": true,
                "targetPath": "$.mailEnabled",
                "scope": "createEntity"
            },
            {
```

```
                "constant": false,
                "targetPath": "$.securityEnabled",
                "scope": "createEntity"
            },
            {
                "constant": "Unified",
                "targetPath": "$.groupTypes[0]",
                "scope": "createEntity"
            }
        ]
    }
}
```

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.52 Procurement Data Warehouse

Follow this procedure to set up Procurement Data Warehouse as a target system.

Prerequisites

- You obtain credentials to access the Procurement Data Warehouse API.

  > **Note**
  >
  > To obtain credentials to access the Procurement Data Warehouse API, create a case to the component *BNS-ARI-PRI*.
  >
  > In response to the case, SAP provides the certificate needed to access the API as well as the URL for the procurement data warehouse enrollment service, which is landscape-specific and starts with `*.cloud.sap`.

- You established trust between your SAP BTP subaccount and the SAP Cloud Identity Services - Identity Authentication service. For more information, see Establishing Trust Automatically.
- To configure your *Procurement Data Warehouse* provisioning system (see the procedure below), you will need to map your SAP Ariba application parameters to the relevant Identity Provisioning properties. The property mapping between the two systems is as follows:

Procurement Data Warehouse Application	Identity Provisioning	Values
API URL	`URL`	Examples: • US: **https://openapi.ariba.com** • Europe: **https://eu.openapi.ariba.com**
procurement data warehouseOAuth Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token**
OAuth Client ID	`client_id`	Enter the OAuth Client id used for access token retrieval.

- To load transaction data into procurement data warehouse, you must have one or more of the following SAP Ariba applications:
  - SAP Ariba Buying
  - SAP Ariba Buying and Invoicing
  - Guided sourcing capability for SAP Ariba Sourcing
  - SAP Ariba Contracts
  - SAP Ariba Spend Analysis

Context

The Procurement Data Warehouse is a capability that feeds analytics information from SAP Ariba applications, including guided sourcing capability for SAP Ariba Sourcing, SAP Ariba Buying and Invoicing, and SAP Spend Control Tower, to the embedded SAP Analytics Cloud. It provides data transfer, storage, loading, and reporting, and it drives visualization through advanced analytics dashboards.

You can use Identity Provisioning to configure Procurement Data Warehouse as a target system where you can provision users and groups. The target system consumes SCIM 2.0 API provided by Procurement Data Warehouse.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *Procurement Data Warehouse* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP Analytics Cloud URL for your Procurement Data Warehouse.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`client_id`	Enter the OAuth client id, generated for your Procurement Data Warehouse. (see the **Prerequisites** section)
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your Procurement Data Warehouse instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page.
`pdw.user.unique.attribute`	It defines by which unique attribute(s) an existing user to be resolved in the event of conflicting users. Default value: **userName** Possible values: • **emails[0].value** • **userName,emails[0].value** **Note** If this property is missing, or you've deleted it, and the service does not find such a *userName*, it will try again to resolve the conflicting user – by *email*. If the second attempt for resolution is unsuccessful too, the creation of the conflicting user fails. For more information, see: List of Properties [page 80]
(Optional)`pdw.group.prefix`	This property distinguishes Procurement Data Warehouse groups by specific prefix. It is an optional property which does not appear by default at system creation. Example value: **PDW_** You can use the example value or provide your own. When **set in the target system**, only groups containing the **PDW_** prefix in their display name will be provisioned to Procurement Data Warehouse. Groups without this prefix in the display name won't be provisioned. If the property is not set, all groups will be provisioned to Procurement Data Warehouse.

Property Name	Description & Value
(Optional) `pdw.support.bulk.operation`	Set this property to *true* if you want to enable SCIM bulk operations for provisioning users. That means, the Identity Provisioning service can write, update, and delete a potentially large collection of users in a single request. For more information, see: SCIM Protocol: Bulk Operations If not specified, the default value is *false*. **Note** SCIM bulk operations are not supported for provisioning groups to Procurement Data Warehouse.
(Optional) `pdw.bulk.operations.max.count`	If you have enabled the SCIM bulk operations, you can use this property to set the number of users to be provisioned per request. Default value: **`20`** **Note** The value must not exceed the number of entities defined by the Procurement Data Warehouse system as a SCIM service provider. Otherwise, the provisioning job will fail with HTTP response code 413 (*Request Entity Too Large*).
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the Procurement Data Warehouse target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your Procurement Data Warehouse system. For more information, see: Manage Transformations [page 2439]

> **Note**
>
> To access the Procurement Data Warehouse API documentation, contact the Procurement Data Warehouse technical support.

Default transformation:

Code Syntax

```
{
    "user": {
        "condition": "isValidEmail($.emails[0].value) &&
(('%pdw.group.prefix%' === 'null') || ($.groups[?(@.display =~ /
%pdw.group.prefix%.*/)] empty false))",
        "mappings": [

['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']",
                "optional": true
            },
            {
                "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:user-custom-parameters:1.0']",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:user-custom-parameters:1.0']",
                "optional": true
            },
            {
                "sourcePath": "$.roles",
                "targetPath": "$.roles",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.photos",
                "targetPath": "$.photos",
                "preserveArrayWithSingleElement": true,
                "optional": true
            },
            {
                "sourcePath": "$.groups[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.groups[?(@.value)]",
                "functions": [
                    {
                      "entityType": "group",
                      "function": "resolveEntityIds"
                    }
                ]
      }
        ]
    },
    "group": {
        "condition": "isAttributeWithOptionalPrefix($.displayName,
pdw.group.prefix) && isAttributeWithOptionalPrefix($
['urn:sap:cloud:scim:schemas:extension:custom:2.0:Group']['name'],
pdw.group.prefix) && (isRegularGroup() || isApplicationSpecificGroup())",
        "mappings": [
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "constant": [
                  "urn:ietf:params:scim:schemas:core:2.0:Group",
```

```
                    "urn:ietf:params:scim:schemas:extension:sap:group-custom-
parameters:1.0"
                ],
                "targetPath": "$.schemas"
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.id",
                "scope": "createEntity",
                "functions": [
                    {
                        "condition": "('%pdw.group.prefix%' !== 'null') &&
(@ =~ /%pdw.group.prefix%.*/)",
                        "function": "replaceFirstString",
                        "regex": "%pdw.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.displayName",
                "targetPath": "$.displayName",
                "functions": [
                    {
                        "condition": "('%pdw.group.prefix%' !== 'null') &&
(@ =~ /%pdw.group.prefix%.*/)",
                        "function": "replaceFirstString",
                        "regex": "%pdw.group.prefix%",
                        "replacement": ""
                    }
                ]
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "function": "resolveEntityIds"
                    }
                ]
            },
            {

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:group-custom-
parameters:1.0']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:group-custom-
parameters:1.0']",
                "optional": true
            }
        ]
    }
}
```

If you try to provision groups that already exist in Procurement Data Warehouse, your provisioning job may fail with: '*The group already exists on the target system and cannot be provisioned*' error. This happens after a reset of the Procurement Data Warehouse target system or if you create a new target system connected to an existing Procurement Data Warehouse backend.

To avoid this, you have the following options:

- Delete the existing group in Procurement Data Warehouse target system.

- Adapt the Procurement Data Warehouse write transformation. Either ignore provisioning of groups or add temporary the *skipOperations* expression for creating groups.
- Avoid provisioning of already existing groups.

5. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

> ⚠ Caution
>
> The **email** attribute is unique for Procurement Data Warehouse but it might not be unique for other systems, such as *SAP SuccessFactors*. That's why, when you choose a source system, make sure that there are no users with duplicate e-mails. If there are such, then after the provisioning job all users with the same e-mail address will be created as a single user in Procurement Data Warehouse.
>
> To learn more, see *Guided Answers*: Multiple Users from a Source System Are Created as One in the Target
>
> To learn more about excluding users from Procurement Data Warehouse target, see: Exclude Users from Provisioning to Target Systems

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

Related Information

Configure OAuth Certificate Authentication [page 2456]

1.6.2.53 SCIM System

Follow this procedure to set up a SCIM system as a target system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Identity Access Governance** bundle option.

- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only if the SCIM system is exposed in a private corporate network. For more information, see Cloud Connector.
- You have technical user credentials for a SCIM system, with read/write access permissions, depending on the scenario you want to implement. In case OAuth is used for authentication, client ID and secret are required when creating a destination for access token retrieval.

Context

Create a general SCIM 2.0 based target system to write users and groups to it.

Procedure

1. (Optional) If the SCIM system is exposed in a private corporate network, add an access control system mapping in Cloud Connector. For more information, see Configure Access Control (HTTP).
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
3. Add *SCIM System* as a target system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the service URL. For example: **`http://<cloudfoundry_server>.com/api/uaa/`**
`ProxyType`	Depending on your network exposure, enter one of the following: • *Internet* • *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	You can specify one of the following: • Technical user ID • Client ID for OAuth HTTP destinations. It's used for retrieving of the access token.

Property Name	Value
`Password`	(Credential) You can enter one of the following: • Technical user password • Client secret for OAuth HTTP destinations. It's used for retrieving of the access token.
`OAuth2TokenServiceURL`	If you need to make OAuth authentication to the system, enter the URL to the access token provider service for OAuth HTTP destinations. For example: **`https://<token_provider>.com/api/oauth2/v2.0/token`**
`scim.csrf.token.path`	Specifies the path which is appended to the URL to retrieve the CSRF token when `scim.api.csrf.protection` is enabled.
`scim.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. If enabled, this property requires the configuration of the `scim.csrf.token.path` property to specify the path where the CSRF token can be retrieved. **Possible values:** • *enabled* • *disabled*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SCIM* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see Manage Transformations [page 2439].

To make group assignments via the user resource, you need to change the default transformation of the target system as described in Enabling Group Assignment [page 2445].

- **Mapping logic** – The behavior of the default transformation logic is to map all attributes from the internal SCIM representation to the target entity. If the entity has e-mail addresses, the first entry will be marked as primary.
- **User off-boarding** – Users can be deleted from the target system. Depending on the implementation, this could be done through a user interface (if such exists) or the SCIM REST API. Users could be deactivated, depending on the SCIM system implementation. The SCIM core schema defines an attribute "**active**", whose definition depends on the service provider. For more information, see SCIM: Singular Attributes

Default transformation:

Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$",
                "targetPath": "$"
            },
            {
                "targetPath": "$.id",
                "type": "remove"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "condition": "$.emails[0].length() > 0",
                "targetPath": "$.emails[0].primary",
                "constant": true
            },
            {
                "type": "remove",
                "targetPath": "$
['urn:ietf:params:scim:schemas:extension:enterprise:2.0:User']"
            }
        ]
    },
    "group": {
        "ignore": true,
        "mappings": [
            {
                "sourcePath": "$",
                "targetPath": "$"
            },
            {
                "targetPath": "$.id",
                "type": "remove"
            },
            {
                "sourceVariable": "entityIdTargetSystem",
                "targetPath": "$.id"
            },
            {
                "targetPath": "$.members",
                "type": "remove"
```

```
            },
            {
                "sourcePath": "$.members[*].value",
                "preserveArrayWithSingleElement": true,
                "optional": true,
                "targetPath": "$.members[?(@.value)]",
                "functions": [
                    {
                        "type": "resolveEntityIds"
                    }
                ]
            }
        ]
    }
}
```

6. Now, add a source system from which to read users and groups. Choose from: Source Systems [page 585]

Next Steps

- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.2.54 SSH Server (Beta)

Follow this procedure to set up an SSH server (Beta) as a target system.

Prerequisites

- You have credentials for a tenant in SAP Business Technology Platform. For more information, see: Accounts
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only when your SSH server resides in a remote system, outside your Neo environment. For more information, see Cloud Connector.

> **Note**
>
> This is a beta feature available on SAP Business Technology Platform. For more information, see: *Enable beta features* in Change Subaccount Details

Context

SSH Server is a system (connector) in beta state. It helps you execute bash scripts through SSH connection. The configuration allows you to attach separate scripts per entity lifecycle callback (such as user create, group create/update, and so on). This system helps you connect to remote machines via SSH tunnel, with or without use of the Cloud Connector, depending on whether the SSH port is visible or not.

The bash scripts can take as parameters fields that are coming from the entity JSON data. For example: *sudo su - vcap /home/myscript.sh $.userName $.email*

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Target Systems*.
2. Add *SSH Server (Beta)* as a target system. For more information, see Add New Systems [page 2415].
3. Choose the *Properties* tab to configure the connection settings for your system.

   Below are listed all available SSH Server properties. Some of them can be mandatory and others – optional, depending on your scenario.

   Mandatory Properties

Property Name	Description & Value
`ProxyType`	Possible values: • **Internet** – if the SSH port is visible in your Neo environment • **OnPremise** – if the SSH port is not directly accessible, and you have to use the Cloud Connector. You have to configure TCP protocol connection to the SSH host and port (specify the configuration properties `ssh.host` and `ssh.port`).
`CloudConnectorLocationId`	Relevant when the proxy type is *OnPremise*. Use it only if your SAP Business Technology Platform account uses more than one Cloud Connector.
`ssh.create.user.command`	Path to the bash command you need to execute to create a user.
`ssh.update.user.command`	Path to the bash command you need to execute to update a user.
`ssh.delete.user.command`	Path to the bash command you need to execute to delete a user.

Property Name	Description & Value
`ssh.create.group.command`	Path to the bash command you need to execute to create a group.
`ssh.update.group.command`	Path to the bash command you need to execute to update a group.
`ssh.delete.group.command`	Path to the bash command you need to execute to delete a group.
`ssh.create.user.command.exit.code.already.exists`	Integer number (code). It's generated by the "`create user`" command when the provisioning job tries to create a user that already exists in the target system.
`ssh.update.user.command.exit.code.not.found`	Integer number (code). It's generated by the "`update user`" command when the provisioning job tries to update a user that is missing from the target system.
`ssh.delete.user.command.exit.code.not.found`	Integer number (code). It's generated by the "`delete user`" command when the provisioning job tries to delete a user that is missing from the target system.
`ssh.create.group.command.exit.code.already.exists`	Integer number (code). It's generated by the "`create group`" command when the provisioning job tries to create a group that already exists in the target system.
`ssh.update.group.command.exit.code.not.found`	Integer number (code). It's generated by the "`update group`" command when the provisioning job tries to update a group that is missing from the target system.
`ssh.delete.group.command.exit.code.not.found`	Integer number (code). It's generated by the "`delete group`" command when the provisioning job tries to delete a group that is missing from the target system.
`ssh.auth.type`	Supported SSH authentication types: • **key** • **pwd** • **otp** • **key+otp** • **key+pwd** • **pwd+otp** • **key+pwd+otp**
`ssh.host`	
`ssh.port`	*22*
`ssh.username`	

Property Name	Description & Value
`ssh.password`	(Credential) Taken into account only if the authentication type includes **pwd**. That means any of the following: • `ssh.auth.type` = *pwd* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+pwd+otp*
`ssh.totp.secret.key`	(Credential) Taken into account only if the authentication type includes **otp**. That means any of the following: • `ssh.auth.type` = *otp* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *pwd+otp* • `ssh.auth.type` = *key+pwd+otp*
`ssh.private.key.type`	The type of SSH private key. Possible values: • **ssh-rsa** • **ssh-dsa** Default value: *ssh-rsa* **Note** If you choose *ssh-rsa*, the key should be in format **PKCS #8**, non-encrypted.
`ssh.private.key`	(Credential) Taken into account only if the authentication type includes **key**. That means any of the following: • `ssh.auth.type` = *key* • `ssh.auth.type` = *key+pwd* • `ssh.auth.type` = *key+otp* • `ssh.auth.type` = *key+pwd+otp*
(Optional) `ips.delete.threshold.groups`	Use this property to control the number of groups to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of groups, for example by adding a filter or condition. For more information, see: List of Properties [page 80]
(Optional) `ips.delete.threshold.users`	Use this property to control the number of users to be deleted in a target system by defining a threshold. This will prevent you from accidentally deleting a huge number of users, for example by adding a filter or condition. For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

4. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SSH Server (Beta)* target system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SSH server. For more information, see Manage Transformations [page 2439].

   Default transformation:

   Code Syntax

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.userName",
                "targetPath": "$.userName"
            }
        ]
    }
}
```

5. Now, add a source system from which to read users. Choose from: Source Systems [page 585]

Next Steps

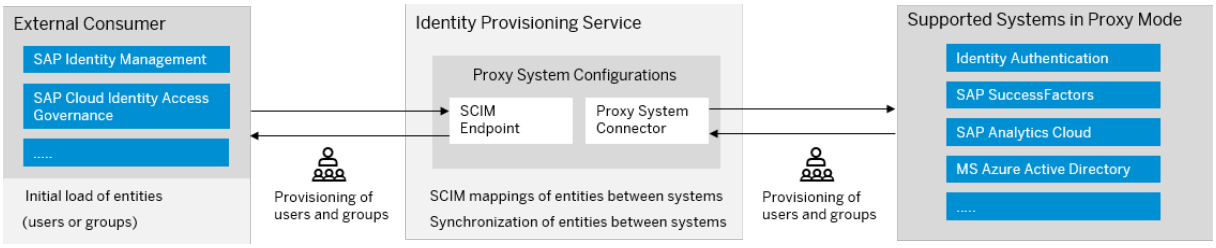
- Before starting a provisioning job, you can first subscribe for e-mail notifications from the source system you use in your scenario. This way, you will be notified by e-mail about eventual failed entities during the jobs. For more information, see Manage Job Notifications [page 3018].
- Start an identity provisioning job. For more information, see Monitor Provisioning Job Logs [page 2982].

1.6.3 Proxy Systems

A proxy system is a special connector type you can use for *hybrid* scenarios.

It exposes any Identity Provisioning supported backend system as a SCIM 2.0 service provider, which can be consumed by any SCIM 2.0 compatible client application, without making a direct connection between them.

After the proxy connector is configured, a consumer application can start sending CRUD requests to the Identity Provisioning proxy connector (which will play the role of a target system). The proxy connector will then read the entities (playing the role of a source system) and provision them to the back-end of the SCIM 2.0 system.



How Proxy Systems Work

Identity Provisioning exposes a SCIM 2.0 based system (connector) as a proxy. Then, an external consumer system regards this proxy connector as its back-end system. To start using a proxy system in your Identity Provisioning tenant, whether it's a bundle or standalone, and depending on the infrastructure or environment it runs on, the following steps need to be performed.

Infrastructure of SAP Cloud Identity Services

Your tenant type meets one of the following requirements:

- Your bundle tenant is created after March 15, 2022.
- Your Identity Provisioning is purchased as a standalone product between September 1, 2020 and October 20, 2020.

1. Sign in to the SAP Cloud Identity Services administration console and navigate to *Users & Authorizations* > *Administrators*.
2. Choose your technical user (administrator user of type **System**). If you don't have a technical user yet, create one. For more information, see Add System as Administrator
3. Configure the technical user authentication.
   - **Certificate**

     Choose *Certificate* > *Configure certificate* and *Upload* your certificate.
     Client certificates are used by HTTP REST clients as a means for SSL certificate authentication.
   - **Secrets**

     Choose *Secrets* > *Add* and provide the required information. After saving it, a Client ID and Client Secret are generated for the technical user. Make sure you copy and save the client secret.
4. Enable the *Access Proxy System API* permission for the technical user.
5. Then navigate to *Identity Provisioning* > *Proxy Systems*, and create a proxy system.
6. (Optional) Export this system as a *.csv* file. This will help an administrator of the external consumer application to import the proxy configuration as a SCIM repository in SAP Identity Management, for example.

   > **Note**
   >
   > The entities exposed by the back-end system will be mapped to SCIM 2.0 entities, if possible. If not possible, the SCIM standard provides a mechanism to define a new resource type with the appropriate schema. You can use the custom resource type to map the back-end entities.
7. Finally, the external application can start sending REST web service requests to the proxy system in order to read identities from the back end of the SCIM 2.0 system. For the authentication, you need to use

the *user ID* and *password* of the Identity Authentication technical user for which you have set permission *Access Proxy System API*. In case you decide to use OAuth authentication, the OAuth token URL should follow the pattern: `https://<ias-tenant-host>/oauth2/token`

How Proxy Transformations Work

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Example

Conditions in Proxy Scenarios

When conditions are applied to users or groups in the proxy *Read Transformation*, the number of returned resources may be “0” or less than the actual number of read entities. This is because some of the entities are filtered out as they don’t match the applied condition. In this example, the returned resources are "0" because all 5 users (items) returned per page are filtered out.

```
Request: GET /Users?startIndex=6&count=5
Response:
{
  "startIndex": 6,
  "itemsPerPage": 5,
  "totalResults": 10,
  "Resources": [],
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:ListResponse"]
}
```

Example

totalResults in Proxy Scenarios

When reading entities from a proxy system, the `totalResults` value returned by the system depends on whether the system API provides a total count (for example, SCIM-based connectors, SAP BTP Platform Members (Cloud Foundry), SAP BTP Java/HTML5 apps (Neo), SAP Application Server ABAP) and whether a transformation condition is applied.

- When the system API supports `totalResults`, the behavior differs depending on whether conditions are defined in the proxy Read Transformation:
  - **No conditions are applied**
    If no conditions are defined in the proxy Read Transformation, Identity Provisioning returns the backend's `totalResults` value directly. This value represents the full number of entities in the system, regardless of `startIndex` and `count`.

For example: There are 1000 users in the proxy system.

```
Request: GET /Users?startIndex=6&count=5
Response:
{
  "startIndex": 6,
  "itemsPerPage": 5,
  "totalResults": 1000,
  "Resources": [/* Users 6 through 10 */],
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:ListResponse"]
}
```

- **Conditions are applied**
  Identity Provisioning always calculates `totalResults`, based on the number of entities that pass the conditions. The backend's value is not used, because it includes entities that may be filtered out.

- When the system API does not support `totalResults` or an equivalent value, Identity Provisioning always calculates `totalResults`.
  Identity Provisioning derives it as follows:
  - If it is not the last page: `totalResults` = `startIndex` + `count`
  - If it is the last page: `totalResults` = exact number of read entities

  As a result, `totalResults` is only an estimate until the last page is reached. A SCIM client that reads all entities from an IPS SCIM Proxy system should use this logic:

```
startIndex = 1
count = N (where N must be between 1 and 100 inclusive; default: 25)
do {
  page = readPage(startIndex, count)
  startIndex += page.itemsPerPage
} while (startIndex <= page.totalResults)
```

  Example request:

```
GET /Users?startIndex=<startIndex>&count=<count>
```

  Do not use `page.Resources.length` to detect the last page. `page.Resources` contains the entities returned for the requested page, unless a transformation condition filters some of them out.
  If a transformation condition is applied:
  - `page.itemsPerPage` contains number of actually read entities, before the condition.
  - `page.Resources` contains only entities that passed the condition, which could be between 0 and count.
  - Pages may contain an empty `Resources` array even when `page.totalResults` is greater than 0 (when no entity passes the specified condition).

  Examples:
  - The system does not provide `totalResults`, there are 150 users in the proxy system and the page size is 100.

```
GET /Users?startIndex=1&count=100 -> page.totalResults == 101,
page.Resources.size == 100
GET /Users?startIndex=101&count=100 -> page.totalResults == 201,
page.Resources.size == 50
GET /Users?startIndex=201&count=100 -> page.totalResults == 150,
page.Resources.size == 0
```

- The system provides `totalResults`, but there is no transformation condition. There are 150 users in the proxy system and the page size is 100.

```
GET /Users?startIndex=1&count=100 -> page.totalResults == 150,
page.Resources.size == 100
GET /Users?startIndex=101&count=100 -> page.totalResults == 150,
page.Resources.size == 50
GET /Users?startIndex=201&count=100 -> page.totalResults == 150,
page.Resources.size == 0
```

- The system provides `totalResults` with transformation condition that filters out each odd entity. There are 100 users in the proxy system and the page size is 50.

```
GET /Users?startIndex=1&count=50 -> page.totalResults == 51,
page.Resources.size == 25
GET /Users?startIndex=51&count=50 -> page.totalResults == 101,
page.Resources.size == 25
GET /Users?startIndex=101&count=50 -> page.totalResults == 150,
page.Resources.size == 0
```

The following table shows how the `totalResults` value is determined when a SCIM proxy endpoint request is made to read entities from a backend system. The outcome depends on three factors: whether the backend system API returns a `totalResults` value, whether conditions are defined in the proxy Read Transformation, and the value of the `ips.proxy.scim.total.results.strategy` property.

- *Provided* - Identity Provisioning returns the `totalResults` value provided by the backend system API.
- *Calculated* - Identity Provisioning calculates `totalResults`, based on the entities returned after conditions are applied.

`totalResults` Support	Conditions Applied	`ips.proxy.scim.total.results.strategy`	Value
Supported	No	Provided/Calculated	Provided
Supported	Yes	Provided	Provided
Supported	Yes	Calculated	Calculated
Not supported	Yes/No	Provided/Calculated	Calculated

For more information, see List of Properties [page 80] → `ips.proxy.scim.total.results.strategy`

How to call a proxy system

As proxy operations cannot be maintained by the Identity Provisioning UI, you need to manage resources (users and groups) by sending SCIM 2.0 API requests to certain endpoints. Below are listed all endpoints and operations available in the Identity Provisioning service. Each provisioning system, however, supports only a specific set of operations.

Tip: The ID of each proxy system (`system_ID` in the table below) is a dash-separated string. You can see it at the end of the system URL in the Identity Provisioning UI.

> ⚠ Caution
>
> Effective *September 2020*, Shanghai (China) tenants that reside on SAP BTP, Neo should be accessed on the following domain: **dispatcher.cn1.platform.sapcloud.cn**
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Depending on the infrastructure/environment your Identity Provisioning tenant (bundle or standalone) runs on, use the relevant URI patterns to call an endpoint:

Resource Operation	HTTP Method	Endpoint
Read users	GET	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users`
Read a user	GET	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users/<user_id>`
Create a user	POST	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users`

Resource Operation	HTTP Method	Endpoint
Update a user (*full*)	PUT	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users/<user_id>`
Update a user (*partial*)	PATCH	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users/<user_id>`
Delete a user	DELETE	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Users/<user_id>`
Read groups	GET	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups`
Read a group	GET	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups/<group_id>`

Resource Operation	HTTP Method	Endpoint
Create a group	POST	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups`
Update a group (*full*)	PUT	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups/<group_id>`
Update a group (*partial*)	PATCH	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups/<group_id>`
Delete a group	DELETE	**Infrastructure of SAP Cloud Identity Services** • **Basic**, **OAuth** and **Certificate** Authentication: `https://<ias-tenant-host>/ipsproxy/service/api/v1/scim/<system_id>/Groups/<group_id>`

Query Parameters for Proxy System SCIM API

When using Identity Provisioning Proxy System SCIM API, you can specify the `attributes` and the `excludedAttributes` query parameters to control which user or group resource attributes to be included or excluded from the response. The `membersType` query parameter is applicable for groups and defines the type of members (user or group) to be included in the response.

> **Note**
>
> The query parameters work for first-level attributes only.

> **Code Syntax**
>
> In this example, "name" is the first-level attribute. The "familyName", "givenName" and "middleName" are second-level attributes and cannot be used as the query parameter value.

```
"name": {
        "familyName": "Armstrong",
        "givenName": "Julie",
        "middleName": "Grace"
      },
```

The query parameter value is the resource attribute name. In case you want to specify multiple attribute names, you need to separate them by comma. Using " " (space) or "," (comma) is not a valid value and results in returning all the resource attributes.

In order for an attribute to be included or excluded from the response, the attribute's schema must be defined in the *Schemas* attribute of the user resource. For example, if you want to return all users with the custom attribute *roomNumber* in the response, the custom schema must be defined in the *Schemas* attribute of the user resource.

The `attributes` and the `excludedAttributes` query parameters can be combined with other parameters, such as: filtering, paging of resources, paging of multi-value attributes.

attributes

When specified, the `attributes` query parameter defines which user or group resource attributes to be included in the response.

This request example returns all users with the *active* and *userName* attributes in the response.

> **Code Syntax**

```
GET /Users?attributes=active,userName
```

This request example returns all groups with the *displayName* attribute in the response.

> **Code Syntax**

```
GET /Groups?attributes=displayName
```

This request example combines the *attributes* query parameter with filtering of a user by *userName*. It returns only the TestUser with both attributes: *active* and *displayName* in the response.

> **Code Syntax**

```
GET /Users?filter=userName eq "TestUser"&attributes=active,displayName
```

In case an attribute is defined in two schemas (for example, the *emails* attribute is defined in the core schema and in the custom schema), you need to specify the schema URI and the attribute name as the

query parameter value. This way, the users will be returned with emails attribute from the specified schema. Otherwise, if you only specify *emails* without the schema URI, the *emails* attribute from both schemas will be returned.

Code Syntax

```
GET /Users?
attributes=urn:ietf:params:scim:schemas:extension:sap:2.0:User:emails
```

excludedAttributes

When specified, the `excludedAttributes` query parameter defines which user or group resource attributes to be excluded in the response.

This request example returns all users with all attributes excluding *userType* in the response.

Code Syntax

```
GET /Users?excludedAttributes=userType
```

This request example returns all groups with all attributes excluding *schemas* in the response.

Code Syntax

```
GET /Groups?excludedAttributes=schemas
```

This request example combines the *excludedAttributes* query parameter with paging parameters *startIndex* and *count* of users. It returns 3 users starting with the first one as the first query result with all attributes excluding *schemas* in the response.

Code Syntax

```
GET /Users?startIndex=1&count=3&excludedAttributes=schemas
```

membersType

When specified, the `membersType` query parameter defines the type of group members (user or group) to be included in the response. You can query for members of all groups or within a certain group. This parameter is supported only for SAP Ariba Applications proxy system.

This request example returns only the user members of all groups.

Code Syntax

```
GET /Groups?membersType=user
```

This request example returns only the user members of a specific group.

Code Syntax

```
GET /Groups/{group-id}?membersType=user
```

This request example returns only the group members of a specific group.

Code Syntax

```
GET /Groups/{group-id}?membersType=group
```

This request example returns the group members of all groups matching the specified query.

Code Syntax

```
GET /Groups?<query>&membersType=group
```

Filters

The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query standard) supports the following filtering capabilities for users and groups:

- *Single entity filter* - Refers to a filtering mechanism that is used to identify a specific single resource (user or group) within a system, based on unique identifiers. Typically, these are userName and email attributes for users and displayName attribute for groups. Identity Provisioning supports only the 'eq' (equal) operator. For example:
  `GET .../Users?filter=userName eq "johnsmith03"`
  `GET .../Groups?filter=displayName eq "accountants"`
- *Delta read filter* - Refers to a filter mechanism used to get a list of resources that have been modified after a specified period of time. Identity Provisioning supports only the 'gt' (greater than) operator. For example:
  `GET .../Users?filter=meta.lastModified gt "2024-02-14T04:42:34Z"`

If your system supports native read filtering, the Identity Provisioning proxy application will translate the SCIM filter to the native system filter, and will try to combine it with the relevant read filter property (for example, `<system_prefix>.user.filter`, `<system_prefix>.group.filter` or `<system_prefix>.origin`). For more information about all read filter properties, see List of Properties [page 80].

Example

Combining filters from the properties and the SCIM request

1. You have the following user mapping in the Read Transformation of a proxy system.

Use Case 1

```
{
    "sourcePath": "$.userName",
    "targetPath": "$.userName",
    "correlationAttribute": true
},
```

Use Case 2

```
{
  "sourcePath":
"$.emails[0].value",

"preserveArrayWithSingleElement":
true,
  "targetPath": "$.emails[0].value"
},
```

2. You set a filter on the *Properties* tab of the proxy system. For example: `scim.user.filter` = *timezone eq "US"*. For more information on the system specific filtering properties, see List of Properties.
3. You execute the SCIM Proxy endpoint request to get a user with a given username or email.
   Use Case 1: `GET .../Users?filter=userName eq "johnsmith03"`

> **Use Case 2**: `GET .../Users?filter=emails[0].value eq "john.smith03@example.com"`
> This query request to the proxy system API will result into:
> **Use Case 1**: `/Users?filter=timezone eq "US" and userName eq "johnsmith03"`
> **Use Case 2**: `/Users?filter=timezone eq "US" and emails[0].value eq "john.smith03@example.com"`

If the Identity Provisioning finds:

- **0** users that meet the filtering criteria, the service returns HTTP status code *200* (OK) with '*totalResults*' set to a value of 0.
- **1** user that meets the filtering criteria, the service returns HTTP status code *200* (OK), and includes the result in the body of the response.
- **More than 1** users that meet the filtering criteria, the service returns HTTP status code *400* (Bad Request) with detail error type '*tooMany*'.
- In the *Read Transformation*, there must be a mapping between the attribute names in `"sourcePath"` and `"targetPath"` (see the example mapping above, where targetPath matches the left side of the used '**eq**' filter).
- Fully qualified names (`<schema>:<attribute>`) are not supported.
  For example: `GET .../Users/urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:employee Number eq '<attribute>'`
- If your system supports multivalued e-mails (that is *$.emails[0].value*, *$.emails[1].value*, etc.), the search criteria will always resolve only one user e-mail. This is the first user e-mail (**$.emails[0].value**).

Proxy scenario example: Hybrid Scenario: SAP Identity Management

SAP Community Blog: Hybrid Scenarios with Identity Provisioning Proxy

1.6.3.1 Identity Authentication

Follow this procedure to set up SAP Cloud Identity Service – Identity Authentication as a proxy system.

Prerequisites

To establish the connection between Identity Provisioning and Identity Authentication, you need to set up the technical user (of type *System*) in Identity Authentication and assign this user the necessary authorizations. You have the option to do it either now, as a prerequisite, or while configuring Identity Authentication as a proxy system, as described in step 5.

Context

Identity Authentication provides authentication and single sign-on for users in the cloud.

You can use the Identity Provisioning user interface (UI) to configure Identity Authentication as a proxy system for hybrid integration, where Identity Authentication is connected to an external identity management system for user and group provisioning. Using the Identity Provisioning you can read corporate users from the external system and provision them to the Identity Authentication user store (and the other way around) without making a direct connection between these systems. This way, you can implement secure authentication, single sign-on (SSO), strong authentication, and mobile SSO so that the provisioned users to Identity Authentication have access to the business applications of your company.

The proxy systems consume SCIM 2.0 API which is provided by Identity Authentication.

There are two versions of the Identity Authentication SCIM API. They are handled by the `ias.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on July 9, 2021) - Identity Authentication SCIM API (in short, SCIM API version 1) is used.

  > **Note**
  >
  > The SAP Cloud Identity Services – Identity Authentication SCIM API (version 1) will be decommissioned on November 30, 2028. You must use its successor, the Identity Directory SCIM API. This requires updating your Identity Authentication connector from version 1 to version 2, as described in Update Connector Version [page 2424].

- When the value is set to **2** - Identity Directory SCIM API (in short, SCIM API version 2) is used. This value is set automatically for all manually created systems in the Identity Provisioning UI after versioning was introduced on July 9, 2021.

SCIM API version 2 is enhanced to support patch operations for proxy systems only, paging for group members and user's groups, custom attributes, delta read mode for users. Also, the group resource mapping in the transformation is not ignored by default, as it is in SCIM API version 1.

To create Identity Authentication as a proxy system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.

2. Save your changes.
3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
4. Save your changes.

3. Navigate to *Identity Provisioning* > *Proxy Systems*.
4. Add *Identity Authentication* as a proxy system. For more information, see Add New Systems [page 2415].
5. Set up the communication between Identity Provisioning and Identity Authentication and configure your authentication method (basic or certificate-based).

> ### Note
> We recommend that you use certificate-based authentication.

   a. In your newly added Identity Authentication proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Manage Certificates [page 2450].

      Skip step **a.** if you want to use basic authentication.

      In SAP Cloud Identity Services administration console, perform the next steps. They are relevant for both basic and certificate-based authentication.

   b. Add System as administrator and provide the respective credentials.

      For basic authentication, provide a password. The user ID will be generated automatically when you set the password for the first time.

      For certificate-based authentication, upload the certificate you have generated in SAP Cloud Identity Services administration console on the previous step.

   c. Save your changes.
   d. Make sure *Manage Users* and *Manage Groups* authorization roles are enabled for the technical user. This way, you can create, edit and delete users and groups in the Identity Authentication user store.

6. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*
URL	Specify the URL of the Identity Authentication tenant of your company. For example: **https://mytenant.accounts.ondemand.com** **Note** If your Identity Authentication Shanghai (China) tenants reside on SAP BTP, Neo, you should use the following URL pattern: *https://<tenant_ID>.accounts.sapcloud.cn/*

Property Name	Description & Value
`ProxyType`	Enter: *Internet* The Identity Authentication is a cloud solution and is outside of your company on-premise infrastructure.
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the Client ID (previously User ID) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*. For example: *1ab7c243-5de5-4530-8g14-1234h26373ab* If your technical user was created before *January 2020*, enter the T-user. For example: *T000003*
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the Client Secret (previously Password) of the Identity Authentication technical user. It is generated automatically for the administrator of type system, when choosing *Secrets* > *Add* > *Save*.

Optional Properties

Property Name	Description & Value
• `ias.<property_name>` • `scim.<property_name>`	When using SCIM API version 2, property names start with `ias` prefix, for example: `ias.user.filter`. When using SCIM API version 1, property names start with `scim` prefix, for example: `scim.user.filter`. For more information, see List of Properties [page 80]. Use the main search or filter properties by *Name* or *System Type* columns.

Property Name	Description & Value
`ias.user.filter`	When specified, only those users matching the filter expression will be read. For example: **name.familyName eq "Smith" and addresses.country eq "US"** This filter will read only users whose family name is "*Smith*" and are living in the *United States*. For more information, see Identity Directory SCIM API: User Search.
`ias.group.filter`	When specified, only those groups matching the filter expression will be read. For example: **displayName eq "ProjectTeam1"** This filter will read only groups, whose display name is "*ProjectTeam1*". For more information, see Identity Directory SCIM API: Group Search.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

7. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Identity Authentication* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Identity Authentication system. For more information, see: Manage Transformations [page 2439]

   Identity Authentication: SCIM REST API Identity Authentication: SCIM REST API

   SCIM API version 2: Identity Directory SCIM API

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default transformations for SCIM API version 1:

Read Transformation	Write Transformation

ension:sap:2.0:Group']
['externalName']"
      }
    ]
  }
}
```

Read Transformation	Write Transformation
`"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']", "optional": true }, { "sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['supportedOperations']", "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['supportedOperations']", "optional": true }, { "sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']", "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName']", "optional": true }] } }`	

→ Remember

If you set `$.userType` to "**public**", all passwords will be written by default in the Identity Authentication. Thus, all provisioned users will successfully sign in to Identity Authentication target system.

When `$.userType` is set to "**employee**", the sign-in behavior of the provisioned users depends on whether users have been created with or without a password, and where these passwords are stored. Thus, you need to modify the target transformations accordingly in order for the users to successfully sign in to the SAP Cloud Identity Services administration console.

To learn more, see *Guided Answers*: Identity Authentication: Provisioned Users Can't Sign In

8. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> **Note**
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> **Caution**

1.6.3.2 Intelligent Opportunity Analyzer

Follow this procedure to set up intelligent opportunity analyzer as a proxy system.

Prerequisites

- You have added *Intelligent Opportunity Analyzer* with *scim* plan in the *Entitlements* page of your subaccount as described in.
- You have created an instance and generated a service key for the *scim* service plan of *Intelligent Opportunity Analyzer*. For more information, see Assigning the Entitlements for Intelligent Opportunity Analyzer to Your Subaccounts.

Context

Intelligent opportunity analyzer is a service that comes integrated with SAP Ariba Category Management for identifying and managing opportunities that lead to improving the performance of a purchasing category.

You can use Identity Provisioning to configure intelligent opportunity analyzer as a proxy system in hybrid scenarios. For example, when intelligent opportunity analyzer is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the intelligent opportunity analyzer.

> **Note**
>
> Intelligent opportunity analyzer does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.

3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
4. Save your changes.

3. Add *Intelligent Opportunity Analyzer* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key. Ensure to append the value `/oauth/token?grant_type=client_credentials`.
(Optional) `ioa.user.filter`	When specified, only those intelligent opportunity analyzer users matching the filter expression will be read. For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Intelligent Opportunity Analyzer* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your intelligent opportunity analyzer system. For more information, see:

Manage Transformations [page 2439]

> ⓘ Note
>
> The documentation for the Intelligent Opportunity Analyzer API and its integration with Identity Provisioning is still under development. Refer to the Intelligent Opportunity Analyzer Setup for updates.

Default read and write transformations

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ### Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.

For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

To learn more, see: Proxy Systems [page 1343]

1.6.3.3 Local Identity Directory

Follow this procedure to set up Local Identity Directory as a proxy system.

Prerequisites

> ⓘ Note
>
> The *Local Identity Directory* connector is available for both bundle and standalone tenants running on SAP Cloud Identity Services infrastructure.

Context

Identity directory is the user store of SAP Cloud Identity Services. It provides a central place for storing and managing users, groups and custom schemas through the System for Cross-domain Identity Management 2.0 REST API, in short Identity Directory SCIM API.

You can use the identity directory for user and group provisioning with an external identity management system without making a direct connection between them. For this, you configure the Local Identity Directory connector as a proxy system in the SAP Cloud Identity Services administration console.

The entities are read and written to and from the identity directory of your current SAP Cloud Identity Services tenant. Therefore, you don't have to set up connectivity and authentication properties for the proxy system. In case you want to use the identity directory in another tenant, add Identity Authentication (version 2) as a proxy system with the respective connectivity set up.

The proxy systems consume Identity Directory SCIM API. It supports patch operations for proxy systems only, paging for group members and user's groups, custom attributes, delta read mode for users. Also, the group resource mapping in the transformation is not ignored by default.

By configuring the directory as a proxy system, you implement secure authentication, single sign-on (SSO), strong authentication, and mobile SSO so that the provisioned users to the directory have access to the business applications of your company.

To create Local Identity Directory as a proxy system, proceed as follows:

Procedure

1. Sign in to SAP Cloud Identity Services administration console and create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to SAP Cloud Identity Services.

   If you already have a technical user, skip this step.

   - For **Certificate-based authentication**, follow the procedure in Manage Certificates for Inbound Connection [page 2456] → *SAP Cloud Identity Infrastructure*
   - For **Basic authentication**, navigate to *Users & Authorizations* > *Administrators* and add an admin user of type **System**. Configure a client ID and secret for this user and enable the *Access Proxy System API* permission.

2. Navigate to *Identity Provisioning* > *Proxy Systems*.
3. Add *Local Identity Directory* as a proxy system.

   For more information, see Add New Systems [page 2415].

4. **Optional:** If needed, choose the *Properties* tab to configure filtering and paging.

   Optional Properties

Property Name	Value
`idds.user.filter`	This property filters users by particular attributes. You can set a single attribute or multiple ones as search criteria. • Value pattern for single attribute: *<user_attribute> eq "<value>"* • Value pattern for multiple attributes: *<user_attribute1> eq "<value1>" and/or <user_attribute2> eq "<value2>"*
`idds.group.filter`	This property filters groups by display name. You can set a single display name or multiple ones as filter criteria. If you enter multiple display names (using **OR** operator), the filter will search for any of them. • Value pattern for single attribute: *displayName eq "<group_name>"* • Value pattern for multiple attributes: *displayName eq "<group_name1>" or displayName eq "<group_name2>"*
`idds.user.groups.paging.enabled`	This property enables paging of user's groups. The maximum number of user's groups returned per request is 1000. To read more than 1000 user's groups, paging must be enabled.

Property Name	Value
`idds.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 20 000. To read more than 20 000 group members, paging must be enabled.

Local Identity Directory properties are prefixed with `idds.<property_name>`. For more information, see List of Properties [page 80].

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

5. **Optional:** Configure transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the Local Identity Directory proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Local Identity Directory. For more information, see:

   - Manage Transformations [page 2439]
   - SCIM API version 2: Identity Directory SCIM API

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

   Default transformations for Local Identity Directory:

"optional": true
}
]
}
}</pre>	

→ Remember

If you set `$.userType` to "**public**", all passwords will be written by default in the Local Identity Directory. Thus, all provisioned users will successfully sign in to Local Identity Directory target system.

When `$.userType` is set to "**employee**", the sign-in behavior of the provisioned users depends on whether users have been created with or without a password, and where these passwords are stored. Thus, you need to modify the target transformations accordingly in order for the users to successfully sign in to the SAP Cloud Identity Services administration console.

To learn more, see *Guided Answers*: Identity Authentication: Provisioned Users Can't Sign In

6. Connect the external consumer to SAP Cloud Identity Services with the technical user you have created in step 1.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> **Note**
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management → sections **Next Steps** and **Future Identity Lifecycle**.

1.6.3.4 SAP Advanced Financial Closing

Follow this procedure to set up SAP Advanced Financial Closing as a proxy system.

Prerequisites

- You have created an instance and generated a service key for the standard service plan of SAP Advanced Financial Closing. For more information, see: How to Manage User Access Using the SCIM API Provided. The service key contains the API URL and the OAuth credentials (`clientid` and `clientsecret`) under the `uaa` property.

Context

SAP Advanced Financial Closing allows you to define, automate, process, and monitor the financial closing tasks for the entities of your organization. It is an SAP BTP application that runs in an SAP BTP subaccount.

You can use Identity Provisioning to configure SAP Advanced Financial Closing as a proxy system and configure it in hybrid scenarios. For example, when SAP Advanced Financial Closing is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management and SAP Cloud Identity Access Governance, without making a direct connection between both systems. You can provision users and user groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and user groups back to the SAP Advanced Financial Closing.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Advanced Financial Closing* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under *endpoints* > *scim2* without adding the path information. For example: `https://afc-production-afc-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user ID provided by the service key under *uaa* > *clientid*.
`Password`	(Credential) Enter the password provided by the service key under *uaa* > *clientsecret*.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL provided by the service key of your SAP Advanced Financial Closing instance. It follows the pattern: **`<uaa.url>/oauth/token`**, where: • `<uaa.url>` is the URL provided by the service key under *uaa* > *url*. • **`/oauth/token`** is the suffix you need to add.
(Optional) `s4hana.afc.user.filter`	When specified, only those SAP Advanced Financial Closing users matching the filter expression will be read. Supported operators: **`eq`** (equal), **`sw`** (starts with) and **`co`** (contains) For example: • *userName eq "Julie Armstrong"* • *emails eq "julie.armstrong@example.com"* • *name.familyName sw "A"* • *name.givenName co "Ju"*
(Optional) `s4hana.afc.group.filter`	When specified, only those SAP Advanced Financial Closing groups matching the filter expression will be read. Supported operators: **`eq`** (equal), **`sw`** (starts with) and **`co`** (contains) For example: *displayName eq "Administrators"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the SCIM Proxy API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy SCIM API.

5. Configure the transformations.

   Transformations are used to map user and group attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Advanced Financial Closing* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Advanced Financial Closing system. For more information, see: Manage Transformations [page 2439].

	}</pre>

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be

automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.5 SAP Advanced Workflow

Follow this procedure to set up SAP Advanced Workflow as a proxy system.

Prerequisites

- You have technical credentials for SAP Advanced Workflow. Note that SAP Advanced Workflow is available to SAP SuccessFactors Incentive Management customers as an optional add-on. You create an Admin user

in SAP SuccessFactors Incentive Management, which is synchronized with SAP Advanced Workflow. For more information, see: Adding an Admin User and Commissions User Synchronization.

- You have set up SSO between Identity Authentication and SAP Advanced Workflow. For more information, see Integration with SAP IdP.

Context

SAP Advanced Workflow enables you to analyse, organize, and execute business processes to connect people, data, and daily activities. Workflow provides you the tools you need to configure and customize your business processes based on your specific business needs.

Create an SAP Advanced Workflow proxy connector to execute hybrid scenarios. That means, it can provision its users to another (external) back-end system by request, and then can continue executing CRUD operations back to the SAP Advanced Workflow system, whenever the external back-end requests such. This scenario supports provisioning **users**.

> **Note**
>
> SAP Advanced Workflow does not support groups.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Advanced Workflow* as a proxy system. For more information, see Add New Systems [page 2415].

4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Advanced Workflow system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP Advanced Workflow system.
`Password`	(Credential) Enter the password for your SAP Advanced Workflow user.
`awf.domain`	The domain name is the name of your SAP Advanced Workflow tenant. If you don't know your tenant name, contact your supervisor or administrator, or refer to the email notification you received when your account was created.

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Advanced Workflow* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Advanced Workflow. For more information, see:

   Manage Transformations [page 2439]

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

    }
}
```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.

- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

> **Note**
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> **Caution**
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.6 SAP Analytics Cloud

Follow this procedure to set up SAP Analytics Cloud as a proxy system.

Prerequisites

- In SAP Analytics Cloud, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- In SAP Analytics Cloud, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Managing OAuth Clients and Trusted Identity Providers

Context

SAP Analytics Cloud is an all-in-one cloud product offered as software as a service for business intelligence, planning, and predictive analytics.

You can use Identity Provisioning to configure SAP Analytics Cloud as a proxy system in hybrid scenarios. For example, when SAP Analytics Cloud is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and groups back to the SAP Analytics Cloud.

There are two versions of the SAP Analytics Cloud SCIM API. They are handled by the `sac.api.version` property as follows:

- When the value is set to **1** or the property is not defined (typical for systems created before versioning was introduced on April 10, 2023), SAP Analytics Cloud SCIM API version 1 is used. This is the default value.
- When the value is set to **2** - SAP Analytics Cloud SCIM API version 2 is used. This version is released with enhancements, among which the support for patch operations.

For more information on the differences between SAP Analytics Cloud SCIM API version 1 and 2, see Managing Users and Teams.

For more information on how to update to version 2, see Update Connector Version [page 2424].

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Analytics Cloud* as a proxy system. For more information, see Add New Systems [page 2415].

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Analytics Cloud system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Analytics Cloud.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Analytics Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Analytics Cloud instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page. For more information, refer to *Authorize API Access for OAuth Clients* in Manage OAuth Clients
`sac.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. This property is automatically added to the system, with default value: **enabled** **Note** If the property is missing, its default value is **disabled**.

Property Name	Description & Value
(Optional) `sac.csrf.token.path`	Path which is appended to the URL to retrieve the CSRF token. The property is automatically added during system creation, when the system in use is SAP Analytics Cloud consuming SCIM API version 2. Based on the version of the SCIM API consumed, the default value for the property is: • SAP Analytics Cloud SCIM API version 1: `/api/v1/scim/Users?count=1` > **Note** > The property is present only for systems created before December 3, 2024. Systems created after this date use the default value for the connector version without adding the property. • SAP Analytics Cloud SCIM API version 2: `/api/v1/scim2/Users?count=1` > **Note** > If you delete the property, the Identity Provisioning will use the default value for the property for SAP Analytics Cloud using SCIM API **version 1**.
(Optional) `sac.group.filter`	When specified, only those SAP Analytics Cloud groups matching the filter expression will be read. > **Note** > You can use this property when SAP Analytics Cloud is based on SCIM API version 2. **Possible values:** For example: *displayName eq "ProjectTeam1"*
(Optional) `sac.api.version`	Handles the version of SAP Analytics Cloud SCIM API. **Possible values:** • *1* - Indicates that SAP Analytics Cloud SCIM API version 1 is used. • *2* - Indicates that SAP Analytics Cloud SCIM API version 2 is used. Default value: *1*

Property Name	Description & Value
(Optional) `ips.http.header.x-ignore-roles-if-missing`	Use this property to control whether users or teams (referred to as groups) should keep their role assignments in SAP Analytics Cloud (SCIM API version 1) when no roles are provisioned. Possible values: • true - Users or teams will keep their role assignments when no roles are provisioned. • false - Users or teams will lose their role assignments when no roles are provisioned. This is the default value. For more information, see SAP note 3092730. In SAP Analytics Cloud (SCIM API version 2), this behavior is managed by `sac.support.patch.operation` property.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Analytics Cloud* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Analytic Cloud. For more information, see:

   Manage Transformations [page 2439]

   SAP Analytics Cloud REST API: Managing Users and Teams

   Managing Users and Teams → api/v1/scim

   Managing Users and Teams → api/v1/scim2

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations for SAP Analytics Cloud SCIM API version 1:

Read Transformation	Write Transformation

> ⚠ Caution
>
> When running a provisioning job to update users or teams (referred to as groups) with role assignments in SAP Analytics Cloud, these role assignments will be removed as a result of the update. This behavior, which can lead to permission issues, is expected because role assignments in SAP Analytics Cloud are not available as group parameters in some source systems, such as Identity Authentication. To preserve existing role assignments when updating users or teams, proceed as follows based on the version of the SAP Analytics Cloud SCIM API:
>
> - For SCIM API version 1, set the `ips.http.header.x-ignore-roles-if-missing` property to *true* in the SAP Analytics Cloud target system. For more information, see the properties table above and the SAP note 3092730.
> - For SCIM API version 2, set the `sac.support.patch.operation` property to *true* in the SAP Analytics Cloud target system.

> ⓘ Note
>
> Updating a user in SAP Analytics Cloud using SCIM API version 2 depends on whether user attributes in SAP Analytics Cloud are mapped to SAML attributes in your identity provider. If this is the case, the values of those attributes are populated by the identity provider and cannot be changed by the SAP Analytics SCIM API or the UI. For more information, see Mapping SAML Attributes to Users.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.7 SAP Application Server ABAP

Follow this procedure to set up SAP Application Server ABAP (AS ABAP) as a proxy system.

Prerequisites

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector.
  For more information on how to make a connection to this on-premise system, follow the procedure in Connect to On-Premise Systems [page 2468].
- You have credentials of a technical user with read and write permissions for AS ABAP, which plays both the role of a user data source and a target system. Via this user, the Identity Provisioning service will call the ABAP public API in order to execute a number of function modules. These function modules are listed in **step 1** from the procedure below.
- The technical user must have the required RFC and security authorizations, as described in SAP Note 3666721.

  > ⓘ Note
  >
  > If the technical user has insufficient security authorization, no users or roles can be read.

Context

SAP Application Server ABAP (AS ABAP) offers a user store and user administration capabilities for maintaining users and their authorizations for AS ABAP applications. You can configure AS ABAP as a proxy system so as to provision entities between AS ABAP and another on-premise system.

> **Note**
>
> During the *Initial Load*, only active ABAP users are read. That means, users that have been created before the initial load job is started, and whose expiration date is after the end of the job. To learn about initial load, see **step 8** below – Transformations.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Open Cloud Connector to add an access control system mapping for **AS ABAP**. This is needed to allow the Identity Provisioning service to access AS ABAP as a back-end system on the intranet. To learn how, see: Configure Access Control (RFC)

   Go to *Cloud To On-Premise* > *Access Control* tab and select protocol *RFC SNC*. Then, expose the following *exact names* as accessible resources:

   - `PRGN_ROLE_GETLIST`
   - `BAPI_USER_GETLIST`
   - `BAPI_USER_GET_DETAIL`
   - `BAPI_USER_CREATE1`
   - `BAPI_USER_ACTGROUPS_ASSIGN`
   - `IDENTITY_MODIFY`
   - `BAPI_USER_DELETE`
   - `PRGN_ACTIVITY_GROUPS_LOAD_RFC`
   - `SUSR_USER_GET_DETAIL_MASS` - available as of `SAP_BASIS 7.58`. For more information, see SAP Note 3631587.

     > **Note**
     >
     > The function module `SUSR_USER_GET_DETAIL_MASS`, which is used for mass reading of user details, does not support the `SAPUSER_UUID.SAP_UID` attribute. To read this attribute, use the function module `BAPI_USER_GET_DETAIL` instead.

   These are Business Application Programming Interface (BAPI) functional modules designed to perform certain tasks in the SAP AS ABAP system, such as retrieving, creating, updating or deleting user data.

For more information about each function module and its parameters, refer to the documentation provided in the SAP system. Logon to your SAP system and run transaction code **SE37**. In the *Function Builder: Initial Screen*, enter the function name, choose *Display* and then *Functional Module Documentation*.

2. Open SAP BTP cockpit, and in your Identity Provisioning subaccount create a destination for the AS ABAP system. To learn how, see: Create RFC Destinations

   The destination configuration is required by the Identity Provisioning service to find the back-end system to be used for reading data. It also provides the credentials of the technical user, needed for the connection to the ABAP public API.

   Below are the fields you have to fill in the cockpit destination before using an AS ABAP client as a proxy system.

   > ### Note
   >
   > In the RFC destination, you can set only JCo properties. Properties starting with `abap` are connector specific and must be set in the Identity Provisioning UI.

Field/Property Name	Value
Name	Enter a destination name.
Type	Select *RFC*.
User	Enter the user for AS ABAP. The *User* field corresponds to property `jco.client.user` in the exported RFC destination.
Password	(Credential) Enter the password for the AS ABAP user. The *Password* field corresponds to property `jco.client.passwd` in the exported RFC destination.
jco.client.client	The property is configured during destination creation in SAP BTP cockpit. Provide the client to be used in the ABAP system. Valid format is a three-digit number.
Proxy Type	Defines the proxy type of the connection you need to provide for your ABAP system. The value is set during destination creation in SAP BTP cockpit. The proxy type *OnPremise* requires the Cloud Connector to access resources within your on-premise network. Enter: *OnPremise*
Direct Connection	

Field/Property Name	Value
jco.client.ashost	Provide the virtual host entry that you have configured in the Cloud Connector → *Access Control* configuration. At least one property specifying the target host must be set during destination creation.
jco.client.sysnr	Provide the "system number" of the ABAP system.
Load Balancing Connection	
jco.client.mshost	Represents the message server host to be used. At least one property specifying the target host must be set during destination creation.
jco.client.r3name	Provide the three-character system ID of the ABAP system to be addressed.
jco.client.msservt	Provide the port on which the message server is listening for incoming requests. You can use this property as an alternative to `jco.client.r3name`.
Optional Properties	
`jco.destination.peak_limit`	The value represents the maximum number of active connections that can simultaneously be created for a destination. For example: *10*
`jco.destination.pool_capacity`	The value represents the maximum number of idle connections kept open by the destination. For example: *5*
`abap.user.name.filter`	Filters user names by a regular expression. The regex can define any kind of search pattern. For example, `abap.user.name.filter` = **^MAR.*** reads all user names that start with *MAR*, such as **MARK**, **MARTINA**, and so on. **Note** This property has a higher priority over `abap.user.filter`. That means, if you set both properties in a system, the value of **abap.user.name.filter** will be used. However, if the value of `abap.user.name.filter` is empty, then **abap.user.filter**'s value will be used instead.

Field/Property Name	Value
`abap.role.name.filter`	Filters user roles by a regular expression. The regex can define any kind of search pattern. For example, `abap.role.name.filter` = **^inter.*** reads all roles which start with *inter*, such as **internal**, **internship**, and so on. **Note** This property has a higher priority over `abap.role.filter`. That means, if you set both properties in a system, the value of **abap.role.name.filter** will be used. However, if the value of `abap.role.name.filter` is empty, then **abap.role.filter**'s value will be used instead.
`abap.user.membership.filter`	Filters users by a regular expression, based on their *Role* memberships in AS ABAP. The regex can define any kind of search pattern. For example, `abap.user.membership.filter` = **(?i)^new.*** reads all users who have an assigned role which starts with *new*. This regex is case insensitive, which means the result can be roles starting with **new**, or **New**, or **NEW**, and so on.
`abap.user.page.size`	Use this property to configure the number of users to be read from SAP Application Server ABAP at once. If the property is not set, the function module `SUSR_USER_GET_DETAIL_MASS` **cannot** be used, even if it is available on the ABAP server. **Note** The property can be used only when the function module `SUSR_USER_GET_DETAIL_MASS` is exposed as an accessible resource and is present on the ABAP server. Even when these conditions are fulfilled, if the property is not set, the function module **cannot** be used. For more information, see SAP Note 3631587. **Possible values**: Default value: *100* The maximum allowed number is 100.

> ### Note
>
> If connection properties, like `User` and `Password`, are configured both in the destination (SAP BTP cockpit) and on the *Properties* tab (Identity Provisioning User Interface), the values set in the destination are considered with higher priority.

3. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
4. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
5. Add *SAP Application Server ABAP* as a proxy system. To learn how, see: Add New Systems [page 2415]
6. From the *Destination Name* dropdown, choose the RFC destination you have created in *step 2*.
7. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Application Server ABAP* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your AS ABAP. For more information, see Manage Transformations [page 2439].

   > ### Note
   >
   > The values of the **entityIdSourceSystem** and **entityIdTargetSystem** attributes store the unique ID of the entity. Do not delete or change this statement!

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

- Use the default transformations if the version of your AS ABAP system is *7.40* or higher. If your system version is *7.31*, you can still use these transformations – just apply SAP Note 1695883.
  NOTE: If a user is *inactive* in the identity management system, the default Write Transformation creates it as *inactive* (locked) in AS ABAP too.

8. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.8 SAP Ariba Applications

Follow this procedure to set up SAP Ariba Applications as a proxy system.

Prerequisites

> **Note**
>
> This topic describes customer-managed configurations for the SAP Ariba Applications proxy system. For SAP-managed configurations, refer to the SAP-Managed SAP Cloud Identity [page 520] documentation.

Next-Generation SCIM API

If you are using the next-generation SCIM API provided by SAP Ariba Applications:

- The Identity Provisioning service must be configured to use the OAuth 2.0 client-credentials flow to obtain access tokens from the Identity Authentication service for calling the SAP Ariba Applications next generation SCIM API. The required dependency must be defined in the configuration of the consumer application. For more information, see Configure Form-Based OAuth Authentication [page 2457].

Current-Generation SCIM API

If you are using the current-generation SCIM API provided by SAP Ariba Applications:

- You have created a client application on SAP Ariba APIs Portal for your integration with Identity Provisioning. This is needed to enable SCIM API for user and group for Ariba Applications. For more information, see Register an Application in SAP Ariba Developer Portal .

  > **Note**
  >
  > If you don't have an SAP Ariba APIs account, go to the SAP Ariba Developer Portal and follow the instructions for sign up. For more information, see Get an SAP Ariba APIs Account.

  To find your *realm* name, log in to your SAP Ariba system. It is embedded in your login URL, as illustrated by the following examples:

  - SAP Ariba Buyer example: `https://s1.ariba.com/Buyer/Main/ad/loginPage/...&realm=`*`mycompany-t`*
  - SAP Ariba Sourcing example: `http://`*`mycompany`*`.sourcing.ariba.com/`
- You have enabled the client application for Identity Provisioning on the SAP Ariba Developer Portal.
- You have generated an OAuth secret for your application. For more information, see Generating the OAuth Secret and Base64 Encoded Client ID and Secret.
  To set up your SAP Ariba Applications provisioning system, you'll need to map your SAP Ariba application parameters to the corresponding Identity Provisioning properties. The mapping is as follows:

SAP Ariba	Identity Provisioning	Values
SCIM API URL	URL	Examples: • US: **https://openapi.ariba.com**

SAP Ariba	Identity Provisioning	Values
		• Europe: **https://eu.openapi.ariba.com** • UAE: **https://mn1.openapi.ariba.com** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
SAP Ariba OAuth 2.0 Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token** • UAE: **https://api.mn1.ariba.com/v2/oauth/token** For more information, see SAP Ariba APIs Portal Discover Strategic Sourcing SCIM API for User and Group Master Data Environment Details.
OAuth Client ID	`User`	Alphanumeric string Example: **aaaa12345-1111-3333-cccc-1234567890**
OAuth Secret	`Password`	Alphanumeric string Example: **aaaGGG1eee12abcdefGHIJK123lmnopTTT**
Application key	`ariba.applications.api.key`	Alphanumeric string Example:**123abc123XYZ000abc123ABC012345**
AN-ID	`ariba.applications.realm.id`	AN<numeric_string> Example: **AN000111222333**

Context

After fulfilling the prerequisites, you can create an SAP Ariba Applications proxy system to load its users into an on-premise system and provision groups and new users back to SAP Ariba Applications.

These proxy systems can consume either the current-generation SCIM API or the next-generation SCIM API provided by SAP Ariba Applications. Identity Provisioning distinguishes between the two by the API URL pattern (the current SCIM API contains **openapi** in the URL, while the next-generation API does not) and by the `AuthType=Form` property, which must be configured only for the next-generation API.

For more information about the SAP Ariba SCIM API scope of support, see SAP Ariba SCIM API.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Ariba Applications* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
URL	Enter the SCIM API URL for your SAP Ariba application (see the **Prerequisites** section). The current-generation SCIM API uses the **openapi** pattern in the URL.
`ProxyType`	Enter: *Internet*

Property Name	Description & Value
`Authentication`	Enter: *BasicAuthentication*
`AuthType`	Enter: *Form* **Relevant for next-generation SCIM API**
`User`	Enter the *Client ID* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`Password`	(Credential) Enter the *Client Secret* for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL for the current-generation or the next-generation SCIM API, as described in the corresponding Prerequisites section.
`ariba.applications.api.dependency.name`	This property holds the value of the dependency name used in the configuration of the SAP Ariba Applications consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. **Relevant for next-generation SCIM API**
`ariba.applications.api.key`	(Credential) Enter your application key (see the **Prerequisites** section). **Relevant for current-generation SCIM API**
`ariba.applications.realm.id`	Enter your AN-ID (see the **Prerequisites** section). **Relevant for current-generation SCIM API**

Property Name	Description & Value
(Optional) `ariba.applications.group.flatten`	This property allows or forbids reading "nested groups" (group structures) from SAP Ariba Applications. If enabled (**true**), group members of type *group* will be ignored during read in order not to be provisioned to target systems that do not support nested groups. Thus, leave the default/predefined **false** value only if you are sure that the consuming external application (identity management system) supports nested groups. Default value: *false* Predefined value (during system creation): *false* Leave the default/predefined value only if you are sure that the consuming external application (identity management system) supports nested groups. **Note** If you set this property to *true* in your proxy system, the execution of requests with parameter `membersType=group` will not be supported.
(Optional) `ariba.applications.group.filter`	When specified, only those SAP Ariba Applications groups matching the filter expression will be read. For example: *displayName eq "ProjectTeam1"*
(Optional) `ariba.applications.support.patch.operation`	Default value: *true*

Property Name	Description & Value
`ariba.applications.group.members.page.size`	SAP Ariba Applications has a hardcoded limit of the number of group members returned per request when reading the group SCIM resources. When the Identity Provisioning reads a group, it compares the number of group members with the value configured for `ariba.applications.group.members.page.size`. Depending on the value you defined for `ariba.applications.group.members.paging.enabled`, you can expect the following results: • In case the number of group members equals or exceeds the configured limit and the property `ariba.applications.group.members.paging.enabled` is enabled, the Identity Provisioning will perform full read of all group members via subsequent requests. • In case the number of group members is less than the configured limit or the property `ariba.applications.group.members.paging.enabled` is disabled, the Identity Provisioning will get the returned group members from the target system. Setting the property `ariba.applications.group.members.paging.enabled` allows you to read groups with a large number of group members. For more information, see ariba.applications.group.members.paging.enabled. Default value: *50*
`ariba.applications.group.members.paging.enabled`	This property enables the full read of group members. When it is set to *true*, all groups with members count exceeding the value defined in `ariba.applications.group.members.page.size` will be fully read by the Identity Provisioning via subsequent requests. **Possible values:** • *true* - Full read of group members is enabled. • *false* - Full read of group members is disabled. Default value: *true*

Property Name	Description & Value
`ariba.applications.user.groups.paging.enabled`	SAP Ariba Applications has a hardcoded limitation over the number of user's groups returned per request. This limit is specified by the property `ariba.applications.group.members.page.size`. To trigger a full read of a user with *'groups'* attribute over the configured value, set `ariba.applications.user.groups.paging.enabled` to *true*. **Possible values:** • *true* - the full read of user's groups is enabled. • *false* - the full read of user's groups is disabled. Default value: *true*

Property Name	Description & Value
`ariba.applications.user.groups.page.size`	The number of user groups that SAP Ariba Application returns per request when reading a user. When the Identity Provisioning reads a user, it compares the number groups assigned with the value configured for `ariba.applications.user.groups.page.size`. Depending on the number of groups assigned to the user, you can expect the following results: • If the number of assigned groups is equal or exceeds the configured value, and the `ariba.applications.user.groups.paging.enabled` property is set to *true*, Identity Provisioning will read all user groups in separate requests. For example, if a user has 6 groups assigned and the value of the page size is set to *2*, Identity Provisioning will send 3 requests to read the user groups. • If the number of assigned groups is less than the configured value for `ariba.applications.user.groups.page.size` or the property `ariba.applications.user.groups.paging.enabled` is disabled, the Identity Provisioning will read all user groups via one request. For example, if a user has 2 groups assigned and the value of the page size is set to *6*, Identity Provisioning will read all user groups via one request. Setting the property `ariba.applications.user.groups.paging.enabled` allows you to read users with a large number of groups assigned. For more information, see `ariba.applications.user.groups.paging.enabled`. Default value: *50*

Exemplary destination (property configuration):

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://openapi.ariba.com
User=aaaa12345-1111-3333-cccc-1234567890
Password=************
OAuth2TokenServiceURL=https://api.ariba.com/v2/oauth/token
ariba.applications.group.flatten=false
ariba.applications.support.patch.operation=true
ariba.applications.api.key=123abc123XYZ000abc123ABC012345
ariba.applications.realm.id=AN000111222333
```

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Applications* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Applications. For more information, see:

   Manage Transformations [page 2439]

   SCIM API for User and Group Master Data

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

The SAP Ariba developer portal

Video: Create application and API approval process

1.6.3.9 SAP Ariba Category Management

Follow this procedure to set up SAP Ariba Category Management as a proxy system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Category Management. For more information, see Creating a SAP Ariba Category Management SCIM Service Instance in Your Subaccount.

> ⓘ Note
>
> This connector has been deprecated as of August 25, 2025, and is no longer needed. Customers with existing configurations should stop running jobs to or from SAP Ariba Category Management provisioning systems.

Context

SAP Ariba Category Management is a cloud-based solution that enables organizations to define and manage purchasing categories and provides actionable market intelligence, category insights, and various tools and templates for developing and operationalizing category strategies that drive business value and performance. This business solution is built on SAP Business Technology Platform (BTP).

You can use Identity Provisioning to configure SAP Ariba Category Management as a proxy system in hybrid scenarios. For example, when SAP Ariba Category Management is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct

connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Ariba Category Management.

> **Note**
>
> SAP Ariba Category Management does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Ariba Category Management* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *scim-v1* field without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token`
(Optional) `cm.user.filter`	When specified, only those SAP Ariba Category Management users matching the filter expression will be read. For example: • *userName eq "SmithJ"* • *emails.value eq "john.doe@example.com"* • *emails.value eq "john.doe@example.com" or emails.value eq "john.d@example.com" or emails.value eq "j.doe@example.com"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Category Management* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Category Management system. For more information, see:

   Manage Transformations [page 2439]

   SCIM APIs for SAP Ariba Category Management

   User Update and Uniqueness

   The write transformation of SAP Ariba Category Management supports two user unique attributes for managing conflict resolution: *username* and *email*. The username is a mandatory attribute, while the email is an optional, multivalue attribute, indicating that a user may have multiple unique emails.

   The uniqueness of a user in the target system is determined not only by the individual attributes or the combination of both, but also by considering whether one or multiple existing users in the target system share the same values for these unique attributes. Have in mind the following specifics when updating an existing user in the target system, in accordance with the configuration of the `cm.user.unique.attribute` property:

   - When `cm.user.unique.attribute`= *userName*
     If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same email, but a different userName, the user provisioning will fail. In this case,

Identity Provisioning will try to create a new user but will fail, since a user with the same email already exists.

- When `cm.user.unique.attribute`= *emails[*].value*
  If a user in the source system, with a specific username and an email, matches an existing user in the target system by the same username, but a different email, the user provisioning will fail. In this case, Identity Provisioning will try to create a new user but will fail, since a user with the same username already exists.
- When `cm.user.unique.attribute`= *userName, emails[*].value*
  - If a user in the source system, with a specific username and multiple emails, matches an existing user in the target system by the same username and at least one identical email, the user in the target system will be updated.
  - If a user in the source system, with a specific username and multiple emails, matches multiple existing users in the target system (each sharing one of the multiple emails but having different usernames), the user provisioning will fail. In this case, the user will neither be created nor updated.

Default read and write transformations

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.

- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution

User Replication Setup

1.6.3.10 SAP Ariba Central Invoice Management

Follow this procedure to set up SAP Ariba Central Invoice Management as a proxy system.

Prerequisites

You have created an instance and generated a service key for the scim service plan of SAP Ariba Central Invoice Management. This step is automated by the booster *Set Up SAP Ariba Central Invoice Management*. For more information, see Setting Up Invoice Processing with SAP Ariba Central Invoice Management (4N6) –> *Set up Configuration Using Booster in SAP BTP Cockpit*.

Context

SAP Ariba Central Invoice Management is an SAP BTP SaaS application running on SAP BTP, Cloud Foundry environment. This application enables central management of supplier invoices from multiple connected systems, such as SAP S/4HANA Cloud Public Edition systems.

You can use Identity Provisioning to configure SAP Ariba Central Invoice Management as a proxy system in hybrid scenarios. For example, when SAP Ariba Central Invoice Management is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Ariba Central Invoice Management.

This scenario supports provisioning users and groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.

4. Save your changes.

3. Add *SAP Ariba Central Invoice Management* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL provided by the service key under the *ips-connector* field without adding the path information. For example: `https://eu10.cim.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the value from the *clientid* field of the service key.
`Password`	(Credential) Enter the value from the *clientsecret* field of the service key.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. This is the value from the *url* field of the service key plus `/oauth/token` For example: `https://<my tenant>.authentication.eu10.hana.ondemand.com/oauth/token`
(Optional) `cim.user.filter`	When specified, only those SAP Ariba Central Invoice Management users matching the filter expression will be read. Example: *name.familyName eq "Smith"* and *addresses.country eq "US"*
(Optional) `cim.group.filter`	When specified, only those SAP Ariba Central Invoice Management groups matching the filter expression will be read. Example: *displayName eq "ProjectTeam1"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Ariba Central Invoice Management* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Ariba Central Invoice Management system. For more information, see:

   Manage Transformations [page 2439]

   User Management (SCIM) for SAP Ariba Central Invoice Management

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

SAP Ariba Central Invoice Management

1.6.3.11 SAP BTP ABAP environment

Follow this procedure to set up SAP BTP ABAP environment as a proxy system.

Prerequisites

- You have user credentials for an external back-end system with read and write permissions.
- To establish the connection between Identity Provisioning and SAP BTP ABAP environment, you need to set up the communication (user, system and arrangement) on SAP BTP ABAP environment. You can do it now (as a prerequisite) or in the process of configuring SAP BTP ABAP environment as a proxy system, as described in step 5.

Context

You can use SAP BTP ABAP environment as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP BTP ABAP environment, whenever the external back-end requests such. This scenario supports:

- Reading of **business users** (Employee) and **business roles** (which are considered as *groups*)
- Writing of **users** and **assignments**

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP BTP ABAP environment* as a proxy system. For more information, see: Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP BTP ABAP environment and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP BTP ABAP environment proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP BTP ABAP environment backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

   For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

   For more information, see Maintain a Communication Arrangement for Inbound Communication

   > **Note**
   >
   > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
   >
   > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP BTP ABAP environment system. You can take the URL from the communication scenario SAP_COM_0193.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`a4c.skip.read.archived`	In the event of archived (disabled) entities in your SAP BTP ABAP environment system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd* (needed for the *Read Transformation*)
`a4c.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP BTP ABAP environment proxy system in a hybrid scenario. • **true** – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties
(Optional) `a4c.roles.filter`	Enter OData filtering for reading roles in the SAP BTP ABAP environment system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**
(Optional) `a4c.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP BTP ABAP environment system. The value must be an integer number.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://12345-aaaaa-3333.abap.hana.ondemand.com
User=MyABAPEnvUser
Password=************
ips.date.variable.format=yyyy-MM-dd
a4c.skip.read.archived=true
a4c.user.roles.overwrite = false
a4c.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
a4c.roles.page.size=30
```

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP ABAP environment* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP ABAP environment system. For more information, see:

   Manage Transformations [page 2439]

   Inbound Service: Business User

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

  }
}
```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource in the *Read Transformation*. To learn how, see Guided Answers: Business Role Description.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.

- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution

> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.12 SAP BTP Account Members (Neo)

Follow this procedure to set up your SAP Business Technology Platform as a proxy system, from and to which you can provision and write members in your Neo account.

Prerequisites

- You have created a new Platform API OAuth client, with API *Account Member Management* and scopes *Manage Account Members* and *Read Account Members*.
  Save the *Client ID* and *Client Secret* as you'll need them when you configure your proxy system. Make sure you save the client secret as you cannot retrieve it later. For more information, see Create a Platform API Client.

Context

The Identity Provisioning service helps companies to automatically manage the user-to-platform roles assignments for SAP Business Technology Platform subaccounts.

You can use SAP Business Technology Platform as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP Business Technology Platform, whenever the external back-end requests such.

The Identity Provisioning service system SAP Business Technology Platform Account Members represents the various authorization mappings managed by the Platform Authorization Management API of SAP BTP as one generic SCIM 2.0 system, with some limitations. For more information, see: Platform Authorization Management API.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP BTP Account Members (Neo)* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
URL	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/platform/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/platform/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the **Account Member Management** API (see the prerequisites).
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_BTP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*
`scp.user.userbase`	This property specifies the host to the identity provider to be used with this proxy system. All provisioned users can be authenticated only by this identity provider. Default value: *accounts.sap.com* If you use another IdP, enter its value as configured in the SAP BTP cockpit. For example: **`<account_ID>.accounts.ondemand.com`**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Account Members* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your proxy system. For more information, see:

Manage Transformations [page 2439]

SAP BTP: Authorization Management API

The *SAP BTP Account Members (Neo)* proxy connector supports SCIM PATCH operation.

The read transformation takes the group name from the source system. However, the names of the SAP BTP platform roles sometimes contain characters that do not fit the SCIM URI specification. As Identity Provisioning service cannot directly use these characters as a SCIM resource ID, it needs to first encode them into base32 ASCII format. The intermediate JSON logic of the proxy system will then use the new encoded ID and write it to the target system. That means, the ID will be decoded in the proxy write transformation during the **patchEntity** operation. For more information, see: Transformation Expressions [page 391] → *patchEntity*

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

1.6.3.13 SAP BTP Platform Members (Cloud Foundry)

Follow this procedure to set up the SAP BTP Platform Members (Cloud Foundry) as a proxy system.

Prerequisites

- You have a global account in SAP BTP with at least one multi-environment subaccount with enabled Cloud Foundry environment.
- You have established trust between your SAP Cloud Identity Services tenant as custom identity provider for platform users and your global account(s) containing these subaccounts. For more information, see Establish Trust and Federation of Custom Identity Providers for Platform Users.
- You have created a CF provisioning user (which is a regular user of type *Employee* in the local identity directory of your SAP Cloud Identity Services tenant) that will be used for provisioning. Give this user

an email address with the following pattern `cf-user-provisioning-<origin_key>@sap.invalid`, where `<origin_key>` is the origin key of the trust configuration for BTP platform users which points to your SAP Cloud Identity Services tenant. You have set an initial password for the user and marked its email adress as *verified*. For more information, see Create a New User and List and Edit User Details.

> **Note**
>
> The password lifetime for the CF provisioning user depends on the password policy set for the *SAP Business Technology Platform* application in the administration console of SAP Cloud Identity Services. For more information, see Set a Password Policy for an Application.

- You have activated the account of the CF provisioning user by opening the *Profile Page* of SAP Cloud Identity Services, in a separate browser session, and changing its initial password. The URL has the following pattern: `https://<tenant ID>.accounts.ondemand.com` or `https://<tenant ID>.accounts.cloud.sap`
- You have created the group *cf-user-provisioning* in your SAP Cloud Identity Services tenant and added the CF provisioning user to it. For more information, see Create a New Group and Add Users to a Group.
- You have added the CF provisioning user as org member with role **Org Manager** to each Cloud Foundry organization where you want to provision users, in the SAP BTP cockpit For more information, see Add Org Members and About Roles in the Cloud Foundry Environment.

Context

The Cloud Foundry environment enables you to create polyglot cloud applications in Cloud Foundry. It contains the SAP BTP, Cloud Foundry runtime service, which is based on the open-source application platform managed by the Cloud Foundry Foundation. For more information, see Cloud Foundry Environment.

When you enable the Cloud Foundry environment in your subaccount, the system automatically creates a Cloud Foundry organization for you. You are able to add platform users as org members and space members and assign roles to grant these users platform access. For more information, see Valid role types .

SAP BTP Platform Members (Cloud Foundry) connector manages org and space members, as well as their role assignments, in the Cloud Foundry environment of a multi-environment subaccount, where a **single** SAP Cloud Identity Services tenant acts as custom identity provider. We recommend that you use the Identity Provisioning service enabled in this SAP Cloud Identity Services tenant.

In SAP BTP Platform Members (Cloud Foundry), groups correspond to roles in particular Cloud Foundry orgs or spaces, thus group members are user assignments of a role in a specific Cloud Foundry org or space. Group names must follow a defined pattern, explained below, to ensure the correct mapping and provisioning of users and their role assignments to the relevant Cloud Foundry organization or space.

> **Note**
>
> The attribute *name*, defined within the *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group* schema, is used to map the users and user assignments of a role to the relevant Cloud Foundry organization or space. The group names follow the respective patterns:
>
> - organization group name: `<org_ID> <org_role>`
> - space group name: `<org_ID> <space_ID> <space_role>`, where `space_ID` can be retrieved using the Cloud Foundry Command Line Interface by executing the command **`cf space --guid`**.

Whereas the group display names adhere to the following patterns:

- organization group display name:
  `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<org_role>`
- space group display name:
  `<btp.cf.pm.group.prefix><btp.cf.pm.landscape>:<org_name>:<space_name>:<space_role>`

You can use SAP BTP Platform Members (Cloud Foundry) as a proxy connector to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP BTP Platform Members (Cloud Foundry), whenever the external back-end requests such.

→ Remember

This connector enables you to write users and user role assignments to Cloud Foundry on *subaccount* level. For provisioning of users and groups to Cloud Foundry on *application* level, refer to SAP BTP XS Advanced UAA (Cloud Foundry) [page 1045]. For more information, see SAP BTP Integration Scenario.

The proxy system consumes `User Account and Authentication API` and `Cloud Foundry V3 API` provided by Cloud Foundry.

Note

In case you have Cloud Foundry environment enabled in multiple Cloud Foundry landscapes or more than one SAP Cloud Identity Services tenants, you must configure a separate SAP BTP Platform Members (Cloud Foundry) connector for each of them.

Note

The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. To enable provisioning of platform users and user role assignments to and from Cloud Foundry environment, create a Support Ticket on component `BC-CP-CF-SEC-IAM`.

   Specify your SAP Cloud Identity Services tenant ID and the origin key of the trust configuration for BTP platform users which points to your SAP Cloud Identity Services tenant. You can find the origin key value in theSAP BTP cockpit. Go to your SAP BTP subaccount, choose *Trust Configuration* and see the value under *Origin Key* for the relevant *Custom Identity Provider for Platform Users*.
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.

- For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
- For **Basic authentication**, proceed as follows:
    1. Add an administrator user of type **System** and configure the basic authentication method for this user.
       If you already have a technical user, skip this step.
    2. Save your changes.
    3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
    4. Save your changes.

4. Add *SAP BTP Platform Members (Cloud Foundry)* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the `email` of the CF provisioning user (see **Prerequisites**).
`Password`	(Credential) Enter the password for the CF provisioning user (see **Prerequisites**).
`btp.cf.pm.origin`	Enter the origin key of your SAP Cloud Identity Services tenant (see **Step 1**). The value of this property is a string, which always ends with the suffix *-platform*. It will be used as the *origin* attribute in the system transformation.

Property Name	Description & Value
`btp.cf.pm.landscape`	Enter the *technical key* or the *host name* of the landscape in which your multi-environment subaccount with enabled Cloud Foundry environment is located. The techical key is available only for the SAP BTP Cloud Foundry regions. For more information, see Regions and API Endpoints Available for the Cloud Foundry Environment. Please note that when the technical key contains an extension index, the correct value is displayed in the *API Endpoint* column instead of the *Technical Key* column of the table. This is an example of a *technical key*: **`cf-eu10-002`**, corresponding to the API endpoint `api.cf.eu10-002.hana.ondemand.com` and host name `cf.eu10-002.hana.ondemand.com` The host name of the landscape can be found by looking up the *API Endpoint* field in the *Overview* tab of your *Cloud Foundry Environment* on subaccount level of the SAP BTP cockpit. The API endpoint has the following format: `https://api.<landscape-hostname>` **Note** If your provisioning job finishes with error *'Name or service not known'*, the value used for technical key is not correct. In that case you can use the host name of the landscape instead.
(Optional) `btp.cf.pm.user.filter`	When specified, only those SAP BTP Platform Members (Cloud Foundry) users matching the filter expression will be read. For example: *userName eq "SmithJ"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Platform Members (Cloud Foundry)* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

> ### Note
>
> Update operation is skipped for users in the default proxy write transformation.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP Platform Members (Cloud Foundry) system. For more information, see:

Manage Transformations [page 2439]

Cloud Foundry V3 API

> ### Caution
>
> Keep in mind that when you add or delete users and user role assignments in SAP BTP Platform Members (Cloud Foundry), the operations order must adhere to the Cloud Foundry Environment hierarchy. In this case, you can expect the following behavior:
>
> - When adding a user as space member, it must already be present as member of the relevant organization with assigned role **Org User**. When deleting an org member, it should be first removed from the spaces of the relevant organization. In case you end up with erroneous entity structure, you can manually add or delete users via the administration console for SAP Cloud Identity Services.
> - When adding user role assignments, you should first add the org roles and afterwards proceed with the space roles. Also, when deleting user role assignments, you should first delete the space roles and then proceed with the org roles. If this condition is not fullfiled the job will finish with error. In that case, you can rerun the job until it finishes successfully.

Default read and write transformations:

> ### → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

8. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>

Related Information

SAP BTP Integration Scenario

1.6.3.14 SAP BTP Java/HTML5 apps (Neo)

Follow this procedure to set up SAP Business Technology Platform as a proxy system, from and to which you can provision user-to-groups assignments for Java/HTML5 applications that run on SAP BTP, Neo environment.

Prerequisites

- You have created a new Platform API OAuth client, with *Authorization Management* scopes. Save the *Client ID* and *Client Secret* as you'll need them when you configure your proxy system. Make sure you save the client secret as you cannot retrieve it later.
  To learn how to create a Platform API client and what are the required platform service roles, see: Create a Platform API Client

Context

The Identity Provisioning service helps companies to automatically manage the user-to-groups assignments for Java/HTML5 applications running on the SAP Business Technology Platform. For this aim, the service reuses data from an active company user store.

For this scenario, SAP Business Technology Platform is a proxy system. That is, the Identity Provisioning service represents the various authorization mappings managed by Authorization Management REST API of SAP BTP as one generic SCIM 2.0 system, with some limitations. For more information, see: Using the Authorization Management REST API

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.

- For **Basic authentication**, proceed as follows:
  1. Add an administrator user of type **System** and configure the basic authentication method for this user.
     If you already have a technical user, skip this step.
  2. Save your changes.
  3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
  4. Save your changes.

3. Add *SAP BTP Java/HTML5 apps (Neo)* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **`https://api.<SAP_BTP_host>/authorization/v1/accounts/<SAP_BTP_account>`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/authorization/v1/accounts/abc123xyz* • (Japan – Tokyo) *https://api.jp1.hana.ondemand.com/authorization/v1/accounts/abc123xyz*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the Client ID of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).
`Password`	(Credential) Enter the Client Secret of the new Platform API OAuth client created for the Authorization Management API (see the prerequisites).
`OAuth2TokenServiceURL`	Enter: **`https://api.<SAP_BTP_host>/oauth2/apitoken/v1`** Examples: • (Europe – Rot) *https://api.hana.ondemand.com/oauth2/apitoken/v1* • (US East – Sterling) *https://api.us3.hana.ondemand.com/oauth2/apitoken/v1*

Property Name	Description & Value
(Optional) `hcp.read.group.roles`	If you set this property to *true*, the Identity Provisioning will read the following additional attributes for a SAP BTP group: • Application roles • Group mappings, defined by your identity provider **⚠ Restriction** This property and the relevant functionality is applicable only if SAP BTP and the external SCIM-based system belong to one and the same region.
(Optional) `hcp.patch.response.with.resource`	Use this property when you execute hybrid scenarios with SAP BTP as a SCIM proxy system, and you update an entity (mostly relevant to groups, like when you change the members of a group) via a PATCH request. Set this property to *true*. This way, the successful PATCH request will return a response code 200 (*OK*) back to the consumer client application with a payload body containing the updated attributes of the relevant group.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP Java/HTML5 apps (Neo)* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your proxy system. For more information, see:

   Manage Transformations [page 2439]

   SAP BTP: Authorization Management API

   The *SAP BTP Java/HTML5 apps (Neo)* proxy connector supports SCIM PATCH operation.

   The read transformation takes the group name from the source system. However, SAP BTP groups names sometimes contain characters that do not fit the SCIM URI specification. As Identity Provisioning service cannot directly use these characters as a SCIM resource ID, it needs to first encode them into base32 ASCII format. The intermediate JSON logic of the proxy system will then use the new encoded ID and write it to the target system. That means, the ID will be decoded in the proxy write transformation during the **patchEntity** operation. For more information, see: Transformation Expressions [page 391] → *patchEntity*

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.15 SAP BTP XS Advanced UAA (Cloud Foundry)

Follow this procedure to set up the SAP BTP XS Advanced UAA (running on SAP BTP, Cloud Foundry environment) as a proxy system.

Prerequisites

You have created credentials to call the REST APIs of the SAP Authorization and Trust Management service on global account, subaccount, or directory level. For more information, see: Get Access to the APIs and btp create security/api-credential.

Context

You can use Identity Provisioning to configure SAP BTP XS Advanced UAA as a proxy system in hybrid scenarios. For example, when SAP BTP XS Advanced UAA is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. Upon provisioning platform users, business users and groups (considered role collections in SAP BTP) to the external backend system, it will trigger CRUD (create, read, update, delete) operations on users back to the SAP BTP XS Advanced UAA.

Create a separate proxy system for each global account, multi-environment subaccount and directory on SAP BTP, and configure the respective credentials and connectivity properties. Depending on where you want to provision your entities, you need to:

- Create a proxy system for the global account to provision **platform users** and groups.
- Create a proxy system for the directory to provision **platform users** and groups.
- Create a proxy system for the subaccount to provision **platform users**, **business users** and groups.

> **Note**
>
> Provisioning of platform users as **org members** and **space members** requires the usage of a different connector: SAP BTP Platform Members (Cloud Foundry). For more information, see SAP BTP Platform Members (Cloud Foundry) [page 1499].

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP BTP XS Advanced UAA (Cloud Foundry)* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
`URL`	Enter the API URL in the following format: `https://api.authentication.<region>.hana.ondemand.com` or For more information, see Call an API.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service in the following format: • `https://<global_account_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or • `https://<subaccount_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or • `https://<directory_subdomain>.authentication.<region>.hana.ondemand.com/oauth/token` or For more information, see Call an API.
`User`	Enter the respective OAuth client ID that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.
`Password`	(Credential) Enter the respective OAuth client secret that was generated when you created credentials for each global account, subaccount and directory. For more information, see Get Access to the APIs.

Property Name	Description & Value
`xsuaa.origin`	Enter the Origin Key of your identity provider. • Identity provider for platform users: In the SAP BTP cockpit, go to your global account (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for platform users. This origin key always ends with `-platform`. • Identity provider for business users: In the SAP BTP cockpit, go to your subaccount (see Navigate in the Cockpit), choose *Security* > *Trust Configuration* and copy the *Origin Key* value used for business (application) users. For example: sap.custom For more information about users with multiple origins, see Configure Single and Multiple Origins [page 1526].
`xsuaa.origin.filter.enabled`	This flag property depends on `xsuaa.origin`. Possible values: **true** or **false** • If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `xsuaa.origin`. • If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. • If set to *true* but the `xsuaa.origin` property is missing, the provisioning will fail.
`scim.support.patch.operation`	Use this property if you want to modify the members of a group. Possible values: • **true** – the Identity Provisioning service will modify the group membership via the *PATCH /Groups* endpoint of UAA. To learn how, see Patch • **false** – the Identity Provisioning service will modify the group membership via the *POST /Groups* or *DELETE /Groups* endpoints of UAA. To learn how, see Add Member and Remove Member .

Property Name	Description & Value
`xsuaa.patch.response.with.resource`	Use this property if you want to retrieve a group whose membership was modified. **Note** This property is usable only when you have configured membership modifications via *Add/Remove Member* UAA endpoints. That is, when the `scim.support.patch.operation` property is set to **false**. Possible values: • **true** – the Identity Provisioning service will return the modified group via the *GET /Groups* endpoint of UAA. To learn how, see Retrieve . • **false** – no modified groups will be returned by the service.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://api.authentication.eu10.hana.ondemand.com*

`OAuth2TokenServiceURL`=*https://myaccount.authentication.eu10.hana.ondemand.com/oauth/token*

`User`=*sb-full-access!a76125*

`Password`=**********

`xsuaa.origin`=*sap.custom*

`xsuaa.origin.filter.enabled`=*true*

`scim.support.patch.operation`=*true*

`xsuaa.patch.response.with.resource`=*false*

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP BTP XS Advanced UAA* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP BTP XS Advanced UAA system. For more information, see Manage Transformations [page 2439] and the API documentation.

- User Management (System for Cross-domain Identity Management (SCIM))- SCIM groups - role collections
- User Management (System for Cross-domain Identity Management (SCIM)) - SCIM users - shadow users

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

    ],
    "scimEntityEndpoint": "Groups"
  }
}</pre>	

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation

is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

SAP BTP Integration Scenario

1.6.3.15.1 Configure Single and Multiple Origins

Configure and provision users with single or multiple origins in SAP BTP XS Advanced UAA (Cloud Foundry) proxy system.

Overview

An origin tells you which is the identity provider of a user in SAP BTP XS Advanced UAA (Cloud Foundry). It is defined in the trust configuration in the SAP BTP cockpit under *Security* > *Trust Configuration* > *Origin Key*.

The origin itself is not a concept of Identity Provisioning. The role of the service is to ensure that you can read and provision users with their identity providers. Once you find the identity provider in the Origin Key, you need to set it in the `xsuaa.origin` property. You can configure it in source, target and proxy SAP BTP XS Advanced UAA (Cloud Foundry) systems. Both single and multiple values are supported. The value is a string that usually specifies the name of the identity provider or its location.

For example: `xsuaa.origin=`*ldap* and `xsuaa.origin=` *ldap;myaccount-xsuaa.accounts.ondemand.com*, where the ";" (semicolon) is the only supported delimiter.

Provisioning Users with Single Origin

You want to configure SAP BTP XS Advanced UAA (Cloud Foundry) as a proxy system for provisioning users with a single origin to and from an external identity management system.

1. On the *Properties* tab of the proxy system, set the `xsuaa.origin.filter.enabled` property to *true*.
   This is a prerequisite for enabling the `xsuaa.origin` property in proxy systems.
2. Enter the value for the `xsuaa.origin` property, for example: *idp1*.
   The value of this property acts like a filter.

Expect the following results:

- When executing a GET request, only users with the origin specified in the `xsuaa.origin` property are returned.
- When executing a POST request to create a user, you make one request to the proxy system. The payload contains the *idp1* origin.
- When executing a PUT request to update a user, you make one request to the proxy system. The payload contains the *idp1* origin.

Provisioning Users with Multiple Origins

You want to configure SAP BTP XS Advanced UAA (Cloud Foundry) as a proxy system for provisioning users with multiple origins to and from an external identity management system.

1. On the *Properties* tab of the proxy system, set the `xsuaa.origin.filter.enabled` property to *true*.
   This is a prerequisite for enabling the `xsuaa.origin` property in proxy systems.
2. Enter multiple values for the `xsuaa.origin` property, for example: *idp1;idp2*.
   The value of this property acts like a filter.
3. On the *Transformations* tab, update the SAP BTP XS Advanced UAA (Cloud Foundry) proxy write transformation. Replace the constant and its value with the sourcePath expression pointing to a multivalue origin attribute:

JSON Text Editor	Graphical Editor
Default mapping: Code Syntax `{ "constant":"%xsuaa.origin%", "targetPath":"$.origin" },`	Default mapping:
Expected mapping: Code Syntax `{ "sourcePath":"$.origin", "targetPath":"$.origin" },`	Expected mapping:

4.
   - When executing a GET request, only users with the origins specified in the `xsuaa.origin` property are returned.
   - When executing a POST request to create a user with two origins (*idp1;idp2*), you should make two separate requests to the proxy system with two separate payloads - the first one containing the *idp1* origin and the second one containing *idp2* origin.
     As a result, two entries for one and the same user are created. Both entries contain the same user attributes (for example, username and email address) and differ only in their origins.
   - When executing a PUT request to update a user with two origins (*idp1;idp2*), you should make two separate requests to the proxy system with two separate payloads - the first one containing the *idp1* origin and the second one containing *idp2* origin.
     As a result, two entries for one and the same user are updated.

> ### Note
>
> Multiple origins are not supported in provisioning scenarios between SAP BTP XS Advanced UAA (Cloud Foundry) source system and SAP BTP XS Advanced UAA (Cloud Foundry) target system.

1.6.3.16 SAP Build Work Zone, advanced edition

Follow this procedure to set up SAP Build Work Zone, advanced edition as a proxy system.

Prerequisites

- You have OAuth credentials for SAP Build Work Zone, advanced edition. To learn how, see SAP Build Work Zone, advanced edition: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a proxy SAP Build Work Zone, advanced edition system to load its users into an on-premise system and provision groups and new users back to SAP Build Work Zone, advanced edition.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Build Work Zone, advanced edition* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP Build Work Zone, advanced edition and configure the authentication method (basic or OAuth certificate-based).

   > ### Note
   >
   > We recommend that you use OAuth certificate-based authentication in the regions where it is supported by SAP Build Work Zone, advanced edition. This authentication method is supported for subaccounts created on the recommended data centers for new customers according to the SAP Build Work Zone, advanced edition documentation.

   a. In your newly added SAP Build Work Zone, advanced edition proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in the SAP Build Work Zone, advanced edition Admin Console and are relevant for certificate-based authentication only.

   b. Login to the SAP Build Work Zone, advanced edition Admin Console and execute substep *2. f. iii. Use X.509 Certificate-Based Authentication* from *Step 3: Configure the Identity Authentication service and the Identity Provisioning service* in Option 1: Create a new tenant .
5. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value
`URL`	Enter the URL related to your SAP Build Work Zone, advanced edition system, in format: **`https://<account><sap_wz_domain>.workzone.ondemand.com`** For example: *https://mytenant.mydomain123.workzone.ondemand.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the OAuth client key, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Enter the OAuth client secret, created for your SAP Build Work Zone, advanced edition tenant (see **Prerequisites**).
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Build Work Zone, advanced edition instance, based on the configured authentication method: • *BasicAuthentication* - **`https://<account><sap_wz_domain>.workzone.ondemand.com/api/v1/auth/token`** For example: *https://myaccountmydomain123.workzone.ondemand.com/api/v1/auth/token* • *ClientCertificateAuthentication* - **`https://<company_uuid>.api-<region_host>.dws.workzone.ondemand.com/api/v2/auth/token`** **Note** The `api-` prefix before `<region_host>` is necessary for using *ClientCertificateAuthentication* authentication. For example: *https://mycompanyuuid123.api-eu-20.dws.workzone.ondemand.com/api/v2/auth/token*

Property Name	Description & Value
`client_id`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth Client id used for access token retrieval.
Optional Properties	
(Optional) `workzone.content.type`	This property makes the SAP Build Work Zone, advanced edition proxy system to send the specified value for the *Content-Type* HTTP header. Example: **application/json** Default value (when not specified): *application/scim+json*
(Optional) `workzone.support.patch.operation`	The default value of this property is **false**. But for SAP Build Work Zone, advanced edition proxy systems, this property appears during creation and its predefined value is *true*. That means, when the Identity Provisioning identifies a changed entity in the back-end system, it will execute the updates as PATCH requests instead of PUT. That means, only the changes will be written in SAP Build Work Zone, advanced edition, instead of provisioning the whole entity data.
(Optional) `workzone.include.if.match.wildcard.header`	This property makes the SAP Build Work Zone, advanced edition target system to send the *If-Match* HTTP header with a value of "*" for every request to SAP Build Work Zone, advanced edition. This header could be used for entity versioning. Default value (when not specified): *false*
(Optional) `workzone.group.filter`	When specified, only those SAP Build Work Zone, advanced edition groups matching the filter expression will be read. For example: *displayName eq "ProjectTeam1"*
(Optional) `ips.failed.request.retry.attempts`	Predefined value: *2*
(Optional) `ips.failed.request.retry.attempts.interval`	Predefined value: *30*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default

transformation for the SAP Build Work Zone, advanced edition proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Build Work Zone, advanced edition. For more information, see:

Manage Transformations [page 2439]

SAP Build Work Zone SCIM API

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

1.6.3.17 SAP Build Work Zone, standard edition

Follow this procedure to set up SAP Build Work Zone, standard edition as a proxy system.

Prerequisites

- You have created an instance and generated a service key for the standard service plan of SAP Build Work Zone, standard edition. For more information, see: Initial Setup.
  The service key contains the API URL and the OAuth credentials (`clientid` and `clientsecret`) under the `uaa` property.

Context

The SAP Build Work Zone, standard edition

You can use the Identity Provisioning UI to configure SAP Build Work Zone, standard edition simplifies access to SAP, custom-built, and third party applications and extensions (both on the cloud and on premise) by establishing a central launchpad. as a proxy system and configure it in hybrid scenarios. For example, when SAP Build Work Zone, standard edition is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management and SAP Cloud Identity Access Governance, without making a direct connection between both systems. You can provision users, groups and users' group assignments to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users, groups and users' group assignments back to the SAP Build Work Zone, standard edition.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.

3. Add *SAP Build Work Zone, standard edition* simplifies access to SAP, as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP Build Work Zone, standard edition API URL from the service key of your SAP Build Work Zone, standard edition instance under `endpoints [portal-service]`. It follows the pattern: `https://portal-service.cfapps.sap.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, from the service key of your SAP Build Work Zone, standard edition instance under `uaa.clientid`.
`Password`	(Credential) Enter the OAuth Client Secret, from the service key of your SAP Build Work Zone, standard edition instance under `uaa.clientsecret`.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL from the service key of your SAP Build Work Zone, standard edition instance. It follows the pattern: `<uaa.url>/oauth/token`. For example: `https://ips-cflp-woaealle.authentication.sap.hana.ondemand.com/oauth/token`

Property Name	Value
(Optional) `cflp.providerId`	Enter a valid providerID value. The provider ID is specified in the Channel Manager of the SAP Build Work Zone, standard edition when defining a new content provider. For more information about configuring the content provider to use the Identity Provisioning service, see: Manage Content Providers (Cloud), Manage Content Providers (On Premise). **Note** All users and groups are provisioned to the proxy SAP Build Work Zone, standard edition system with the providerID defined for this proxy system. If you want to use different providerIDs, you need to create separate proxy systems for every providerID.
(Optional) `cflp.user.filter`	When specified, only those SAP Build Work Zone, standard edition users matching the filter expression will be read. By default, users are always filtered by the providerId. If another filtering attribute is defined, for example the email of the user, both filters are combined. Possible values: • **`emails.value eq "john.smith@example.com"`** **Note** Although, the email is supported as a filtering attribute, it is not returned when searching for the user. • **`urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq "ABC123"`** Combining filter attributes is allowed using the and operator, for example: **`emails.value eq "john.smith@example.com" and urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq "ABC123"`**

Property Name	Value
(Optional) `cflp.group.filter`	When specified, only those SAP Build Work Zone, standard edition groups matching the filter expression will be read. By default, groups are always filtered by the providerId. Possible values: • **`externalId eq 12345678`** • **`urn:ietf:params:scim:schemas:extension:2.0:mapping.providerId eq 'ABC123'`** • **`meta.isIAG eq true`** This filtering attribute indicates whether the group will be used in a hybrid scenario with SAP Cloud Identity Access Governance.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the SCIM Proxy API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy SCIM API.

5. Configure the transformations.

   Transformations are used to map user and group attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Build Work Zone, standard edition* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Build Work Zone, standard edition system. For more information, see: Manage Transformations [page 2439].

   ### User Update and Uniqueness

   The proxy write transformation of SAP Build Work Zone, standard edition supports three user unique attributes: *externalId*, *email* and *providerId*. Only providerId is mandatory in combination with at least one of the other attributes. Based on the combinations of these attributes, there can be distinguished three types of users:

   - User 1 - with *email* and *providerId*, but no *externalId*
   - User 2 - with *externalId* and *providerId*, but no *email*
   - User 3 - with all three attributes: *externalId*, *email* and *providerId*

   The uniqueness of the user is ensured by the combination of two unique attributes: the *providerId* and *externalId* or the *providerId* and the *email*.

Updating an existing user in the proxy system depends on how the user is identified there (its combination of unique attributes) and whether Identity Provisioning is aware of this user:

- The existing user was created by a provisioning job (that is, the service is aware of this user).
  If the following attributes are changed in the source system: the *email* of user 1, the *externalId* of user 2, or the *email* or *externalId* of user 3, after running a new job, Identity Provisioning will update the existing user.
- The existing user was not created by a provisioning job or was created by one but afterwards the source and the proxy systems have been reset (that is, the service is not aware of this user).
  If the following attributes are changed in the source system, expect the subsequent results after running a new job:
  - Changing the *email* of user 1 will result in creating a new user in the proxy system, because the user won't match the combination of two unique attributes: *email* and *providerId*.
  - Changing the *externalId* of user 2 will result in creating a new user in the proxy system, because the user won't match the combination of two unique attributes: *externalId* and *providerId*.
  - Changing the *email* or the *externalId* of user 3 will result in updating the user in the proxy system, because the user will still match a combination of two unique attributes. However, changing both, the *email* and the *externalId*, of user 3 will result in creating a new user in the proxy system, because the user will match only one unique attribute - the *providerId*.

```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Related Information

Configure Integration with the Identity Provisioning Service

1.6.3.18 SAP Business Network

Follow this procedure to set up SAP Business Network as a proxy system.

Context

> **Note**
>
> Currently, the SAP Business Network connector cannot be used by customers due to API access constraints. SAP is working on resolving these constraints to make the connector fully operational and accessible.

SAP Business Network, formerly known as Ariba Network, is a cloud-based offering that makes it possible for buyers and suppliers to collaborate on transactions, strengthen their relationships, and discover new business opportunities.

You can use Identity Provisioning to configure SAP Business Network as a proxy system in hybrid scenarios. For example, when SAP Business Network is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group members back to the SAP Business Network.

> **Note**
>
> Identity Provisioning cannot create and delete groups in SAP Business Network target system. It can only update existing groups by adding or removing group members. Therefore, groups must have been created in SAP Business Network.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.

4. Save your changes.

3. Add *SAP Business Network* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the SAP Business Network API URL.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Business Network system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Business Network system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.
`bn.api.key`	An API Key represents the unique key that identifies a particular application as a legitimate consumer of an API.
`bn.realm.id`	The realm name is part of the URL you use to access SAP Business Network.
(Optional) `bn.user.filter`	When specified, only those SAP Business Network users matching the filter expression will be read. For example: • *userName eq "Julie Armstrong"* • *userName sw "J"* • *emails eq "julie.armstrong@example.com"* For more information, see List of Properties [page 80]
(Optional) `bn.group.filter`	When specified, only those SAP Business Network groups matching the filter expression will be read. For example: *displayName eq "Employees"* For more information, see List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ### Note
>
> The Identity Provisioning implementation of the SCIM Proxy API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Business Network* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Business Network system. For more information, see:

   Manage Transformations [page 2439].

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Related Information

SAP Business Network

1.6.3.19 SAP Central Business Configuration

Follow this procedure to set up SAP Central Business Configuration (in short, CBC) as a proxy system.

Prerequisites

- You have created a technical user with administrator permissions that will be used to call the API of SAP Central Business Configuration for reading, creating and updating user and group member information.

Context

Create an SAP Central Business Configuration proxy connector to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the CBC system, whenever the external back-end requests such. This scenario supports provisioning **users** and **group members**.

> ⚠ Caution
>
> You can't create or delete groups on CBC. That means:
>
> - On the attempt to create a group on CBC, Identity Provisioning will only add new members or update existing ones. Also, if you read a group from the external back-end system, there must be a group with the exact same display name (case sensitive) in the CBC system. Otherwise, an error will be thrown and the group members will not be updated.
> - On the attempt to delete a group on CBC, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Central Business Configuration* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your CBC system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Specify the technical user for your CBC system.
`Password`	(Credential) Specify the password for your technical user.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://mycbcaccount.authentication.us2.hana.ondemand.com/oauth/token**
(Optional) `cbc.user.filter`	When specified, only those CBC users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**

Property Name	Value
(Optional) `cbc.group.filter`	When specified, only those CBC groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Central Business Configuration* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your CBC system. For more information, see Manage Transformations [page 2439].

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution

Related Information

SAP Central Business Configuration – Collection

1.6.3.20 SAP Commerce Cloud

Follow this procedure to set up SAP Commerce Cloud as a proxy system.

Prerequisites

- In SAP Commerce Cloud, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Configuring OAuth Client.

Context

SAP Commerce Cloud is a highly flexible and modular platform for delivering modern customer experiences. It provides a standardized, automated, end-to-end solution that allows your projects to release code from repository to cloud.

You can use Identity Provisioning to configure SAP Commerce Cloud as a proxy system in hybrid scenarios. For example, when SAP Commerce Cloud is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group back to the SAP Commerce Cloud.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Commerce Cloud* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Commerce Cloud system. The URL follows the pattern: `https://backoffice.<tenant>. model-t.cc.commerce.ondemand.com` You can find the correct URL in the *Environments* section of SAP Cloud Portal.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Commerce Cloud.

Property Name	Description & Value
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Commerce Cloud.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Commerce Cloud instance. This token URL is listed in the *OAuth Clients* section of the *App Integration* page.
(Optional) `cc.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails.value`**, and **`externalId`**, according to the API syntax of SAP Commerce Cloud. For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators.
(Optional) `cc.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *displayName eq "ProjectTeam1" or "Students2018"*
(Optional) `cc.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for proxy systems: *true*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Commerce Cloud* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Commerce Cloud. For more information, see:

Manage Transformations [page 2439]

Commerce Cloud SCIM Web Services API Documentation

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Related Information

SAP Cloud Identity Services Integration Architecture → cloudscimwebservices extension

1.6.3.21 SAP Concur

Follow this procedure to set up SAP Concur as a proxy system.

Prerequisites

- You are using User v1 API, Identity v4 API or SCIM v4 API.

  > **Note**
  >
  > The **User v1 API** has been decommissioned. For more information, see Concur User API Decommission.

- Your SAP Concur admin user has obtained a *Company Request Token* and a *Company UUID* from the SAP Concur Company Request Token self-service tool.
  For more information, see SAP Concur Company Request Token.

Context

Companies that use SAP Concur for managing and controlling travel expenses, invoices and other can use Identity Provisioning service to automate the identity and access management for the SAP Concur solution. This service allows you to use SAP Concur as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP Concur, whenever the external back-end requests such. This scenario supports reading and writing of **users**.

The SAP Concur integration with Identity Provisioning is supported with Standard and Professional editions.

SAP Concur provides different APIs for integration with Identity Provisioning, resulting in different connector versions. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `concur.api.version` property controls which API you use.

- When the value is set to **3**, the SCIM v4 API is used. It supports reading and provisioning of users and groups.
  By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced. The default version is the latest released connector version at the time the system is created.
- When the value is set to **2**, the Identity v4 API is used. This applies to systems created between December 8, 2021, and December 1, 2025. Identity v4 API supports provisioning of users with the `userUUID` attribute, which is generated by Identity Authentication at user creation.
- When the value is set to **1**, or the property is not defined, the User v1 API is used. This applies to systems created before versioning was introduced on December 8, 2021. Version 1 is deprecated.

For more information on how to update to the connector version you need, see: Update Connector Version [page 2424].

To create SAP Concur as a proxy system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Concur* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Version 1 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	For EU2 data center, enter: **`eu2.concursolutions.com`** For US2 data center, enter: **`www.concursolutions.com`**
`ProxyType`	Enter: **`Internet`**
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *1* to use User v4 API.
`Authentication`	Enter: *BasicAuthentication*
`User`	Deprecated property. Do not use.
`Password`	Deprecated property. Do not use.
`X-ConsumerKey`	Deprecated property. Do not use.

Property Name	Description & Value
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com

Version 2 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *2* to use the Identity v4 API. This was the default value for systems created between December 8, 2021, and December 1, 2025.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.

Property Name	Description & Value
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com
(Optional) `concur.user.filter`	When specified, only those users matching the filter expression will be read. For example: • *userName* eq "johnsmith@example.com" As the userName must be unique in SAP Concur, this filter returns only the user matching this userName. • *companyId* eq "aa067ada-71a9-4f57-8e98-9300b1c3171d" This filter returns all users in the company with this companyId.

Connector Version 3 Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication*
`concur.datacenter`	Specify the SAP Concur data center your Identity Provisioning tenant belongs to. The following SAP Concur data centers are available: • APJ1 • EU2 • US2 Based on the provided data center, Identity Provisioning configures the URL of the User v1 API or Identity v4 API as follows: • If you provide **`us2`**, the URL is: `us.api.concursolutions.com`

Property Name	Description & Value
`concur.api.version`	Defines the version of SAP Concur API. Set the value to *3* to use the SCIM v4 API. By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced.
`concur.authorization.code`	(Credential) Enter the *Company Request Token* and run a provisioning job within 24 hours from generating the token in the SAP Concur Company Request Token self-service tool. Otherwise, the token will expire, and you'll need a new one. After the first run of the job, Identity Provisioning fills in automatically a refresh token as the value of the concur.refresh.token property. If a provisioning job has not been run for six months, you'll again need to generate a new token. → Remember The company request token has a 24 hour validity. If this token expires, you must request a new token. The refresh token has a six month validity. Every time you run a provisioning job, the validity of the refresh token is extended with six months starting from the date of the last run. If you haven't run a provisioning job for six months, your refresh token will expire and you must request a new company request token.
`concur.company.id`	Enter the *Company UUID* as described in the *Prerequisites* section.
`concur.company.domain`	Enter your company domain. The username and the company domain are concatenated in the default transformation in the following format: user@domain Your company domain is the part of your username behind the @ symbol. For example: johnsmith@example.com

Property Name	Description & Value
(Optional) `concur.user.filter`	When specified, only those users matching the filter expression will be read. For example: • *userName* eq "JohnSmith" • *userName* sw "John" • *urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber* eq "00102345"
(Optional) `concur.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *displayName* eq "ProjectTeam1"
(Optional)`concur.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for target systems: *false*
(Optional) `concur.group.members.page.size`	The number of group members that SAP Concur returns per request when reading a group. Default value: 1000
(Optional) `concur.group.members.paging.enabled`	This property enables paging of group members. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Concur* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Concur. For more information, see:

Manage Transformations [page 2439]

SAP Business Accelerator Hub: Concur (Users)

User v1 API: User v1

Identity v4 API: Identity v4

SCIM v4 API: SCIM v4 API

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformation when using User v1 API (connector version 1):

Read Transformation	Write Transformation

	{
	"constant": "DEFAULT",
	"targetPath": "$.LedgerCode"
	}
	]
	}
	}</pre>

⚠ Caution

The User v1 API requires an initial password setup for all newly provisioned user accounts. The default transformation offers a statement with an empty string as a value for the password configuration. However, it is ignored in order to prevent from a default setup of a wrong initial password for your systems. While the password statement is ignored, the provisioning will not be working. To enable the provisioning to SAP Concur, you need to perform the following operations:

1. Enable the password statement. To do this, either delete **"ignore": true,** or set it as **"ignore": false**.
2. Set a proper statement for the password attribute value (**"targetPath": "$.Password"**).

(Optional) You can leave the default empty string, or you can use the **randomPassword** function to calculate a random value for the initial password of the newly created SAP Concur accounts. If you choose one of these two options and if you are not using single sign-on solution for SAP Concur, you have to also arrange a password reset support process in your company. This will securely offer an initial password to your corporate users for their newly created SAP Concur accounts. For more information, see Transformation Expressions [page 391] → **Transformation Functions**.

Default read and write transformation when using Identity v4 API (connector version 2):

The Identity Provisioning does not provide group resource mapping in the SAP Concur write transformation. Although you cannot provision groups to SAP Concur, you can group the users into organizational units by enhancing your target transformation. For more information, see: SAP Concur (Target System) [page 1085]

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.22 SAP CPQ

Follow this procedure to set up SAP CPQ (Configure, Price, and Quote) as a proxy system.

Prerequisites

- You have created a technical user with administrator permissions that will be used to call the API of SAP CPQ for reading, creating and updating user and group information.
- Make sure all users from the external consumer system that have been not provisioned via Identity Provisioning and you would like later to be written in SAP CPQ, have an organization unit name. This unit name must correspond to an existing company system ID in SAP CPQ. The *organization unit* and the *company system ID* must be exactly the same. Users with empty (missing) organization units will not be provisioned, as well as users whose organization units don't match any of the SAP CPQ company system IDs for the relevant tenant.
- In order for a created user to be active in SAP CPQ, it should be assigned to an SAP CPQ target group, whose ID ends with suffix *–USERTYPE*. To learn more, see SAP CPQ: SCIM API → section **Mappings between SCIM API and SAP CPQ** → `groups`.

Context

SAP CPQ is a highly configurable system designated to help sales representatives to configure products, apply pricing and generate quotes. SAP CPQ is part of the SAP Sales Cloud portfolio.

Create an SAP CPQ proxy connector to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the SAP CPQ system, whenever the external back-end requests such. This scenario supports provisioning **users** and **groups**.

> ⚠ Caution
>
> You can't create or delete groups on SAP CPQ. That means:

- On the attempt to create a group on SAP CPQ, Identity Provisioning will only add new members or update existing ones. Also, if you read a group from the external back-end system, there must be a group with the exact same display name (case sensitive) in the SAP CPQ system. Otherwise, an error will be thrown and the group members will not be updated.
- On the attempt to delete a group on SAP CPQ, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP CPQ* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP CPQ and configure the authentication method (basic or OAuth certificate-based).

   > **Note**
   >
   > We recommend that you use OAuth certificate-based authentication.

   a. In your newly added SAP CPQ proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip this step if you use basic authentication. The next steps are relevant for OAuth certificate-based authentication only. For more information, see Configure OAuth Certificate Authentication [page 2456].

   b. Convert your certificate file from `.crt` to `.cer`.

c. Login to SAP CPQ and navigate to *Security* > *Certificate Management* > *User Certificates* > *New Certificate* and upload the certificate to the technical user of SAP CPQ.

   Make sure the *Enable User Certificates* option is turned on. Additionally, the technical user must be set to *Active*.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`cpq.user.filter`	(Optional) When specified, only those SAP CPQ users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**
`OAuth2TokenServiceURL`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the OAuth 2.0 Token Service URL. For example: `https://<cpq_url>/oauth2/token`
`Password`	Valid if *BasicAuthentication* is configured as authentication method. (Credential) Specify the password for your technical user.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the URL to the API of your SAP CPQ system. It is the same as your SAP CPQ tenant URL. It must contain the domain name. For example: **https://sample1234.mycpqdomain.com**
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the Username of your SAP CPQ technical user.

Property Name	Value
`cpq.group.members.page.size`	When the `cpq.group.members.paging.enabled` property is set to true, this setting defines the size of the paged members request. **Note** If you configure `cpq.group.members.page.size` to a number greater than the default value, the complete member retrieval is disabled. Default Value: **100** The number of group members that SAP CPQ returns per request when reading a group.
`cpq.group.members.paging.enabled`	This property enables the complete retrieval of group members through additional sequential requests. The maximum number of group members returned per request is 100 as defined in `cpq.group.members.page.size`. For more information, see `cpq.group.members.page.size`. Possible Values: • **true** - Paging is enabled. • **false** - Paging is disabled. Default Value: **true**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP CPQ* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP CPQ system. For more information, see:

   Manage Transformations [page 2439].

   SAP CPQ: SCIM API

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

After the proxy connector is configured, a consumer application can start sending CRUD requests to it. That means, initially reading all (or a filtered set of) entities, and creating them in the SCIM 2.0 back-end of the consumer application. The proxy connector can continue read newly created or updated entities and provision them to the proxy system's back-end.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management → sections **Next Steps** and **Future Identity Lifecycle**.

REMEMBER! When creating a new user in the consumer application, you have to do the following mandatory settings:

- Enter *organization unit* for the user, because this is a mandatory attribute for SAP CPQ. An organization with that exact name must already exist in SAP CPQ, otherwise the new user will not be provisioned.

- In order the new user to be active, add a group privilege for it of type *–USERTYPE*. To learn more, see SAP CPQ: SCIM API → section **Mappings between SCIM API and SAP CPQ** → `groups`.

> ⚠ Caution
>
> Effective September 2020, Neo tenants from Shanghai (China) can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.23 SAP Data Custodian

Follow this procedure to set up SAP Data Custodian as a proxy system.

Prerequisites

- You have created an SAP Data Custodian tenant.
- You have created a user within your tenant with the required roles for your scenario.
- You have added your user to SAP Identity Service Management (SAP ISM).

Context

SAP Data Custodian is a robust Software as a Service (SaaS) solution that protects sensitive data stored in public, private, hybrid, and multicloud environments. This solution integrates with partnered public hyperscalers, SAP applications, and SAP managed clouds.

You can use Identity Provisioning to configure SAP Data Custodian as a proxy system to execute hybrid scenarios. For example, when SAP Data Custodian is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision entities to the external backend system, which can trigger CRUD (create, read, update, delete) operations back to the SAP Data Custodian. This scenario supports provisioning **users** and **user assignments to groups**.

SCIM API 2.0 does not support managing of group assignments via the SCIM user resource. The "groups" attribute of the user is read-only. This means that the user group assignments should be managed via the SCIM group resources using the "members" attribute (as it is defined by the SCIM standard).

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add SAP Data Custodian as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP Data Custodian and configure the authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Data Custodian source system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip this step if you use basic authentication. The next steps are performed in SAP Data Custodian and are relevant for certificate-based authentication only.

   b. Login to SAP Data Custodian tenant and create a tenant operations technical user (TOTU), as described in Create a Tenant Operations Technical User in SAP Data Custodian.

   c. Upload the outbound certificate that you downloaded in **substep a.** to the TOTU, as described in Register the Outbound Certificate to Your Tenant Operations Technical User.
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP Data Custodian SCIM API excluding the path information. `https://<SCIM_API_URL>` For more information, see Identity Provisioning.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* Enter the OAuth client key, created for your SAP Data Custodian tenant. For more information, see Basic Authentication Prerequisites.
`Password`	Valid if *BasicAuthentication* (Credential) Enter the OAuth client secret, created for your SAP Data Custodian tenant. For more information, see Certificate Authentication Prerequisites.
`OAuth2TokenServiceURL`	Specify the URL of the access token provider service for your SAP Data Custodian instance: `https://<SCIM_API_URL>/kms/scim/v1/Oauth2/Token`
`dc.user.filter`	When specified, only those SAP Data Custodian users matching the filter expression will be read. You can filter users by *userName*, *displayName* or *externalId*. **Possible values:** For example: *userName eq "Smith.J"*

Property Name	Value
`dc.group.filter`	This property filters groups by display name or externalId. When specified, only those groups matching the filter expression will be read. **Possible values:** • *SAP_Data_Custodian_Auditor* • *SAP_Data_Custodian_Service_Admin* • *SAP_Data_Custodian_Key_Admin* • *SAP_Data_Custodian_Key_User* For example: *displayName eq "SAP_Data_Custodian_Auditor"*
`dc.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users in the target system. This means, for example, that if a user attribute is modified, only this change will be provisioned and applied in the target system. • If set to *false*, PUT operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. Users can be updated in the target system in various cases, such as: • In the source system, some user attributes are modified, or new attributes are added. • In the source system, a condition or a filter is set for users not to be read anymore. • A user is deleted from the source system. In the last two cases, it's possible to keep the entity in the target system – it will not be deleted but only disabled. To do this, use the `deleteEntity` scope in the transformation of your target or proxy system. See: Transformation Expressions [page 391] → **deleteEntity**. **Possible values:** • *true* • *false* Default value: *false*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the SAP Data Custodian proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   > ### Note
   >
   > When Identity Authentication is configured as a source system, the default transformation logic:
   >
   > - Provisions only groups and user group assignments if they are part of the following predefined group list:
   >   - *SAP_Data_Custodian_Auditor*
   >   - *SAP_Data_Custodian_Service_Admin*
   >   - *SAP_Data_Custodian_Key_Admin*
   >   - *SAP_Data_Custodian_Key_User*
   > - Skips some of the attributes from the identity records.
   > - Sets primary email for `userName` of the user.
   >
   > This way, the transformation logic ensures that the identity data, sent to the Identity Provisioning SCIM REST API, is consistent.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Data Custodian. For more information, see:

   Manage Transformations [page 2439]

   SAP Data Custodian SCIM 2.0 API

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Related Information

SAP Data Custodian

1.6.3.24 SAP Datasphere

Follow this procedure to set up SAP Datasphere as a proxy system.

Prerequisites

- In SAP Datasphere, you have enabled a custom SAML Identity Provider, for which *User Attribute* is set to **Custom SAML User Mapping**. To learn how, see: Enabling a Custom SAML Identity Provider
- In SAP Datasphere, you have added an OAuth client with authorization grant **Client Credentials**. To learn how, see: Create OAuth2.0 Clients to Authenticate Against SAP Datasphere

Context

SAP Datasphere is a solution that harmonizes data management, analytics, and intelligent planning, including capabilities of SAP Data Intelligence Cloud and SAP Analytics Cloud. The solution enables SAP customers to consolidate their SAP data and analytics needs into a single SAP solution.

You can use Identity Provisioning to configure SAP Datasphere as a proxy system in hybrid scenarios. For example, when SAP Datasphere is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Datasphere.

> **Note**
>
> SAP Datasphere does not support groups.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Datasphere* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Datasphere system without adding the path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID to retrieve the OAuth access token for SAP Datasphere.
`Password`	(Credential) Enter the client secret to retrieve the OAuth access token for SAP Datasphere.
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Datasphere instance. This token URL is listed in the *Trusted Identity Providers* section of the *App Integration* page. For more information, see Create OAuth2.0 Clients to Authenticate Against SAP Datasphere
`ds.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. This property is automatically added to the system, with default value: **enabled**

Property Name	Description & Value
(Optional) `ds.user.filter`	When specified, only those SAP Datasphere users matching the filter expression will be read For example: *userName eq "SmithJ"*
`ds.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, Identity Provisioning sends a **PATCH** request to the user or group resource in the target system. Only attributes without `"scope": "createEntity"` in the attribute mappings in the write transformation will be updated. For example, if the last name of a user is changed in the source system, the patch operation will update it in the target system and will leave unchanged other attributes with explicitly set "scope": "createEntity". • If set to *false*, **PUT** operations are used to update users in the target system. This means, for example, that if a user attribute is modified, all user attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Datasphere* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Datasphere. For more information, see:

   Manage Transformations [page 2439]

   SAP Datasphere SCIM 2.0 API

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations:

	}
	]
	}
	}</pre>

> ### Note
>
> Updating a user in SAP Datasphere depends on whether user attributes in SAP Datasphere are mapped to SAML attributes in your identity provider. If this is the case, the values of those attributes are populated by the identity provider and cannot be changed by the SAP Datasphere SCIM API or the UI. For more information, see Map SAML Attributes to Users and Create a User.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is

configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.25 SAP Enable Now

Follow this procedure to set up SAP Enable Now as a proxy system.

Prerequisites

- You have created a technical user in SAP Enable Now with the necessary permissions for establishing a connection with Identity Provisioning.

Context

The SAP Enable Now solution is SAP's digital adoption platform. It can help you improve the adoption, productivity, and efficiency of your software by providing in-application help and e-learning content to users.

You can use Identity Provisioning to configure SAP Enable Now as a proxy system in hybrid scenarios. For example, when SAP Enable Now is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Enable Now.

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Enable Now* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP Enable Now system. It follows the pattern: • `https://<company-name>.enable-now.cloud.sap` • `https://<company-name>.sap-enable-now.cn` (relevant for China)
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the username of the SAP Enable Now technical user.
`Password`	(Credential) Enter the password of the SAP Enable Now technical user.
(Optional) `en.user.filter`	When specified, only those SAP Enable Now users matching the filter expression will be read For example: *userName eq "SmithJ"*
(Optional) `en.group.filter`	When specified, only those SAP Enable Now groups matching the filter expression will be read. For example: *userName eq "SmithJ"*

Property Name	Description & Value
`en.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, **PATCH** operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, **PUT** operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Enable Now* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Enable Now. For more information, see:

   Manage Transformations [page 2439]

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external

application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations:

Read Transformation	Write Transformation

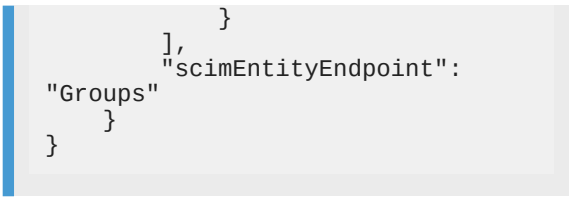
Read Transformation	Write Transformation
	


6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Related Information

SAP Enable Now

1.6.3.26 SAP Fieldglass

Follow this procedure to set up a proxy connector for SAP Fieldglass.

Prerequisites

- You have created an API application key and a web service. To do that, follow the steps on page: Create API Application Key or Web Service and Web Services Setup
  You will need the values of *Virtual Person Name (Username)* and *License Key* for the configuration of your proxy system (**step 6** below).

Context

You can use SAP Fieldglass as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP Fieldglass, whenever the external back-end requests such. This scenario supports:

- Reading of **users** and **groups**
- Writing of **users** and **assignments**

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Fieldglass* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify your SAP Fieldglass environment URL. For example: *https://abc123.fgvms.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter your *Virtual Person Name (Username)* – see the **Prerequisites** section above.
`Password`	(Credential) Enter your *License Key* – see the **Prerequisites** section above.
`OAuth2TokenServiceURL`	Enter your OAuth token URL in the following format: `https://<Environment_URL>/api/oauth2/v2.0/token` For example: *https://abc123.fgvms.com/api/oauth2/v2.0/token*

Property Name	Value
`fg.support.patch.operation`	This property controls how modified users in the source system are updated in the target system. • If set to *true*, **PATCH** operations are used to update users in the target system. • If set to *false*, **PUT** operations are used to update users in the target system. Default value: *false* For more information, see: List of Properties [page 80]

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Fieldglass* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Fieldglass. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Fieldglass

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution

1.6.3.27 SAP Field Service Management

Follow this procedure to set up SAP Field Service Management as a proxy system.

Prerequisites

You have OAuth credentials for SAP Field Service Management. For more information, see: Generating Client ID & Secret

Context

SAP Field Service Management is a cloud-based solution that is used to resolve customers issues with end-to-end field service management. For example, it helps customers overcome resource limitations, such as having enough skilled technicians in all locations.

You can use the Identity Provisioning user interface (UI) to configure SAP Field Service Management as a proxy system in hybrid scenarios. For example, when SAP Field Service Management is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group members back to the SAP Field Service Management.

This scenario supports provisioning **users** and **group members**. When integrated with Identity Provisioning, SAP Field Service Management supports the following group concept:

- A user is created with a default group assigned. A group is mapped to a company (one of the key organizational units in SAP Field Service Management). When using the Identity Provisioning service API, the group is returned as follows:

  ```
  <GroupName>_<CompanyName>
  ```

- A user can have one group assignment for each company. As in SAP Field Service Management a user can be assigned to multiple companies, this requires a group assignment for each of the companies the user can access. A user cannot be assigned to different groups mapped to one and the same company.

> ⚠ Caution
>
> You cannot create or delete groups in SAP Field Service Management. In this case, you can expect the following behavior:
>
> - If a new group is created in the source system (for example, Identity Authentication) and you run the provisioning job to SAP Field Service Management, the job will fail and no group will be created in the target system.
> - If a group exists both in the source system (for example, Identity Authentication) and the target system - SAP Field Service Management, running a provisioning job will only add new members or update existing ones. In this case, groups in the source and target systems must have the same display name (case sensitive). Otherwise, the job will fail, and no group members will be updated.

- If a group exists in the target SAP Field Service Management system and you try to delete it, Identity Provisioning will only remove its group members. In this case, the relevant group members must exist in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Field Service Management* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP Field Service Management system. It follows the pattern: `https://<cluster>.fsm.cloud.sap`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Field Service Management system.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Field Service Management system.

Property Name	Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://<cluster>.fsm.cloud.sap/api/oauth2/v2/token`
(Optional) `fsm.user.filter`	When specified, only those SAP Field Service Management users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**
(Optional) `fsm.group.filter`	When specified, only those SAP Field Service Management groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Field Service Management* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Field Service Management system. For more information, see:

   Manage Transformations [page 2439].

   SAP Field Service Management - SCIM API

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

	"Groups"
	}
	}</pre>

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be

automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

1.6.3.28 SAP HANA Cloud Database Services

Follow this procedure to set up SAP HANA Cloud Database Services as a proxy system.

Prerequisites

You have created a technical user for Identity Provisioning in the SAP HANA database with the OPERATOR and ROLE ADMIN system privileges. For more information, see SAP Identity Provisioning Service → *Prerequisites*.

Context

SAP HANA Cloud allows you to consume the SAP HANA database from cloud applications running on SAP Business Technology Platform, as well as from applications running elsewhere using the standard SAP HANA clients. Every instance of SAP HANA Cloud has its own single SAP HANA Database.

You can use the Identity Provisioning user interface (UI) to configure SAP HANA Cloud Database Services as a proxy system in hybrid scenarios. For example, when SAP HANA Cloud Database Services is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and roles to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and user role assignments back to the SAP HANA Cloud Database Services.

The SAP HANA Cloud Database Services connector supports provisioning of entities to the following two database types:

- SAP HANA Database (HDB)
- SAP HANA Data Lake Relational Engine (HDLRE / IQ Database)

You can define the target database type by setting the `hana.cloud.db.instance.type` property to either `hdb` or `hdlre`.

For more information on the supported database types, see SAP HANA Cloud, SAP HANA Database and SAP HANA Cloud, Data Lake.

> **Note**
>
> In SAP HANA Cloud Database Services, groups correspond to roles.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP HANA Cloud Database Services* as a proxy system. For more information, see Add New Systems [page 2415].

4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Authentication`	Enter: *BasicAuthentication*
`hana.cloud.db.instance.type`	Refers to the database type configured or used within SAP HANA Cloud. The value can be set to: • **hdb** - SAP HANA Database • **hdlre** - SAP HANA Data Lake Relational Engine Default value: **hdb**
`hana.cloud.db.instance.id`	Refers to a unique identifier associated with a specific database instance within the SAP HANA Cloud.
`hana.cloud.db.providerName`	Specifies the identity provider (IdP) that users managed through Identity Provisioning will use for authentication. The provider must be configured to support the authentication method specified in `hana.cloud.db.authenticationType`. For more information on how to obtain the value, refer to the create a JWT provider step in the User Provisioning with Identity Provisioning Service.
`hana.cloud.db.authenticationType`	Specifies the method by which users managed through Identity Provisioning authenticate when connecting to the database. The authentication method is set to *JWT* (users authenticate via JWT tokens issued by an identity provider) during system creation.
`hana.cloud.db.user.filter`	(Optional) When specified, only those SAP HANA Cloud Database Services users matching the filter expression will be read. Example: **name.familyName eq "Smith"**
`hana.cloud.db.group.filter`	(Optional) When specified, only those SAP HANA Cloud Database Services roles matching the filter expression will be read. Example: **displayName eq "ProjectTeam1" or "Employees2020"**

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: `https://demo-hc-3-test.authentication.sap.hana.ondemand.com/oauth/token` For more information on how to obtain the value, refer to the create a service binding step in the User Provisioning with Identity Provisioning Service.
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.
`ProxyType`	Enter: *Internet*
`Type`	Enter: *HTTP*
`URL`	Enter the SAP HANA Cloud Database Services API URL. For example: `https://api.gateway.orchestration.<cluster>-<datacenter>.hanacloud.ondemand.com`
`User`	Enter the OAuth Client Id, created for your SAP HANA Database system. For more information on how to obtain the value for the technical user, refer to the procedure in the User Provisioning with Identity Provisioning Service.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP HANA Cloud Database Services* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP HANA Cloud Database Services system. For more information, see:

Manage Transformations [page 2439].

> ### Note
>
> Given that the SAP HANA Database username attribute is immutable and the email is not supported, refer to Handling Specific Attributes for your provisioning scenarios, particularly with Identity Authentication.

Default read and write transformations:

> ### → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ### Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.

For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

To learn more, see: Proxy Systems [page 1343]

User Provisioning

1.6.3.29 SAP Integrated Business Planning

Follow this procedure to set up SAP Integrated Business Planning (in short, SAP IBP) as a proxy system.

Prerequisites

- You have user credentials for an external back-end system with read and write permissions.
- To establish the connection between Identity Provisioning and SAP Integrated Business Planning, you need to set up the communication (user, system and arrangement) on SAP Integrated Business Planning. You can do it now (as a prerequisite) or in the process of configuring SAP Integrated Business Planning as a proxy system, as described in step 5.

Context

SAP Integrated Business Planning is a cloud-based solution that combines sales and operations planning (S&OP), forecasting and demand, response and supply, demand-driven replenishment, and inventory planning.

You can use Identity Provisioning to configure SAP IBP as a proxy system to execute *hybrid* scenarios. For example, when SAP IBP is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision entities to the external backend system, which can trigger CRUD (create, read, update, delete) operations back to SAP IBP.

SAP Integrated Business Planning provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. By default, the Identity Provisioning service uses API version *1*. The value of the `ibp.api.version` property controls which API you use.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. It supports reading of **business users** (employee) and **business roles** and

writing of **business users** and **role assignments**. In SAP Integrated Business Planning version 1, groups correspond to roles, thus group members are user assignments to a role.
For more information on how to update to version *2*, see Update SAP Integrated Business Planning.

- When the value is set to *2*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users** with their **assignments** to user groups and roles.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Integrated Business Planning* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP Integrated Business Planning and configure your authentication method (basic or certificate-based).

   > ### Note
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Integrated Business Planning proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Integrated Business Planning backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

For basic authentication, provide *User Name* and *Password*.

For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

c. Create a communication system and assign the created user to the communication system.

For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

- When `ibp.api.version=1` is set in Identity Provisioning for the SAP IBP proxy system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

> **Note**
>
> The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
>
> The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

- When `ibp.api.version=2` is set in Identity Provisioning for the SAP IBP proxy system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

> **Note**
>
> The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP IBP system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*

Property Name	Description & Value
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol '**,**' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol '**,**' (comma) as it is not supported.
`ibp.api.version`	The API version which is consumed by the SAP Integrated Business Planning system. By default, Identity Provisioning uses version *1*.
`ibp.skip.read.archived`	In the event of archived (disabled) entities in your SAP IBP system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it. **Relevant for connector version 1**
`ips.date.variable.format`	*yyyy-MM-dd*

Property Name	Description & Value
`ibp.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP IBP proxy system in a hybrid scenario. • **true** – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Relevant for connector version 1**
(Optional)`ibp.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to **true**, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to **false**, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false* **Relevant for connector version 2**
(Optional) `ibp.roles.filter`	Enter OData filtering for reading roles in the SAP IBP system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option** **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `ibp.group.filter`	When specified, only those SAP Integrated Business Planning groups matching the filter expression will be read. Supported operators: eq (equal), co (contains), and sw (starts with). **Possible values::** • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For example: • *displayName co "ProjectTeam1" or "Students2023"* • *externalId eq "12345678" or externalId sw "123"* • *urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type eq "authorization" and externalId eq "12345678"* **Note** These combinations are valid for both 'or' and 'and' operators. **Relevant for connector version 2**
(Optional) `ibp.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP IBP system. The value must be an integer number. **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `ibp.user.filter`	When specified, only those SAP Integrated Business Planning users matching the filter expression will be read. You can filter users by **list of attributes** according to the API syntax of SAP Integrated Business Planning. You can set a single attribute or multiple ones as filter criteria. If you enter multiple attributes (using OR operator), the filter will search for any of them. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values:** • `userName` • `externalId` • `emails[0].value` For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName sw "J" or externalId eq "P000252"* • *userName eq "johnbrown" and emails[0].value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails[0].value ne "johnbrown@email.com" or externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators. **Relevant for connector version 2**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://my1234567-api.scmibp.ondemand.com
User=MyIBPuser
Password=************
ips.date.variable.format=yyyy-MM-dd
ibp.skip.read.archived=true
ibp.user.roles.overwrite = false
ibp.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
ibp.roles.page.size=30
```

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP IBP* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP IBP. For more information, see:

   Manage Transformations [page 2439]

   SAP Integrated Business Planning API: Business User

   SAP Business Accelerator Hub: SAP IBP

   Integrate Cross-Domain Identity Management

   SCIM Interface for IAM

   Default read and write transformations for connector version 1:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource in the *Read Transformation*. To learn how, see Guided Answers: Business Role Description.

Default read and write transformations for connector version 2:

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ### Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`

So make sure you use the correct domain when you construct your REST API requests.

For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

To learn more, see: Proxy Systems [page 1343]

1.6.3.30 SAP Intelligent Agriculture

Follow this procedure to set up SAP Intelligent Agriculture as a proxy system.

Prerequisites

- You have onboarded your SAP Intelligent Agriculture tenant as described in the Onboarding with the SAP BTP Cockpit section of the *Administration Guide for SAP Intelligent Agriculture*.
- You have OAuth credentials for SAP Intelligent Agriculture. For more information, see: Getting the Credentials from the SAP Intelligent Agriculture Instance.

Context

SAP Intelligent Agriculture enables agribusinesses to sustainably increase farming efficiency by digitizing their farming processes and services from plan-to-harvest, taking advantage of data science and machine learning capabilities.

You can use Identity Provisioning to configure SAP Intelligent Agriculture as a proxy system in hybrid scenarios. For example, when SAP Intelligent Agriculture is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group members back to the SAP Intelligent Agriculture.

⚠ Caution

You can't create or delete groups on SAP Intelligent Agriculture. That means:

- On the attempt to create a group on SAP Intelligent Agriculture, Identity Provisioning will only add new members or update existing ones. Also, if you read a group from the external back-end system, there must be a group with the exact same display name (case sensitive) in the SAP Intelligent Agriculture system. Otherwise, an error will be thrown and the group members will not be updated.
- On the attempt to delete a group on SAP Intelligent Agriculture, Identity Provisioning will only remove its members (group assignments). And this can happen only if the relevant group assignments have been provisioned/are present in the target system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Intelligent Agriculture* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Intelligent Agriculture system, in format: **`https://*.prod-<region>.ia.agribusiness.cloud.sap`** , where *: is the name of your subaccount. For example: **`https://custom-domain.prod-eu10.ia.agribusiness.cloud.sap`**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth Client Secret, created for your SAP Intelligent Agriculture instance (see **Prerequisites**).

Property Name	Value
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Intelligent Agriculture instance, in format: **`https://<TENANT>.authentication.<REGION>.hana.ondemand.com/oauth/token`**
(Optional) `ia.user.filter`	When specified, only those SAP Intelligent Agriculture users matching the filter expression will be read. For example: *userName eq "Smith.J"* For more information, see List of Properties [page 80]
(Optional) `ia.group.filter`	When specified, only those SAP Intelligent Agriculture groups matching the filter expression will be read. **Possible values:** • *intagri_Data_Scientist* • *intagri_Farm_Manager* • *intagri_Operator* • *intagri_Operations_Planner* • *intagri_Master_Data_Manager* • *intagri_Administrator* For example: *displayName eq "intagri_Master_Data_Manager"* For more information, see List of Properties [page 80]

Property Name	Value
`ia.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, **PATCH** operations are used to update users and groups in the target system. This means, for example, that if a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to *false*, **PUT** operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. **Possible values:** • *true* • *false* Default value: *false*
`ia.include.if.match.wildcard.header`	Makes the connector send the *If-Match* HTTP header with a value of "*" for every request to the target system. This header could be used by an SAP Intelligent Agriculture system for entity versioning. **Possible values:** • *true* • *false* Default value: *false*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ⓘ Note
>
> The Identity Provisioning implementation of the SCIM Proxy API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Intelligent Agriculture* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

> ### Note
>
> When Identity Authentication is configured as a source system, the default transformation logic:
>
> - Provisions only groups and user group assignments if they are part of the following predefined group list:
>   - *intagri_Data_Scientist*
>   - *intagri_Farm_Manager*
>   - *intagri_Operator*
>   - *intagri_Operations_Planner*
>   - *intagri_Master_Data_Manager*
>   - *intagri_Administrator*
> - Skips some of the attributes from the identity records.
>
> This way, the transformation logic ensures that the identity data, sent to the Identity Provisioning SCIM REST API, is consistent.

> ### Note
>
> When a user is deleted from the SAP Intelligent Agriculture target system, depending on the off-boarding user handling it can be deleted or set to anonymized.
>
> If you try to read such user, you get only its *id* and the other attributes have value `ANONYMOUS`.
>
> If you try to create again a user with the same unique attributes (`userUuid`, `externalId`, `userName`, and `emaill`) during the configured retention period, the existed entity is restored to its active state. If the create operation requests changes in the values of the attributes, they will be executed after triggering a resync job.
>
> For more information, see Data Retention Manager.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Intelligent Agriculture system. For more information, see:

Manage Transformations [page 2439].

SAP Intelligent Agriculture SCIM API

Default read and write transformations:

> ### → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.31 SAP Jam Collaboration

Follow this procedure to set up SAP Jam Collaboration as a proxy system.

Prerequisites

- You get OAuth credentials for SAP Jam Collaboration. If your SAP Jam tenant is of "SCIM provisioning" type, an OAuth client is automatically created for it, with the name **SCIM API Client**. How to find this client:
  1. Go to the SAP Jam Collaboration admin panel.
  2. Choose *Integrations* > *OAuth Clients*.
  3. For *SCIM API Client*, choose *View*.
  4. Save the *Key* and *Secret* values – you'll need them later while configuring your SAP Jam Collaboration provisioning system.

  To learn more, see: SAP Jam: Add an OAuth Client

Context

After fulfilling the prerequisites, follow the procedure below to create a proxy SAP Jam Collaboration system to load its users into an on-premise system and provision groups and new users back to SAP Jam.

> ⚠ Restriction
>
> Bear in mind the following limitations for the number of sent requests during a provisioning job:
>
> - The **SAP Jam SCIM API** allows up to 13,000 requests per hour and up to 200 requests per minute.
> - The Identity Provisioning service can handle the 200 requests per minute limit. If more requests are sent during the minute, the service will "wait" until it can execute them.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Jam Collaboration* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL related to your SAP Jam system, in format: **`https://<SAP_Jam_datacenter>.sapjam.com`** For example: *https://jam4.sapjam.com*
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth client key, created for your SAP Jam tenant (see **Prerequisites**).
`Password`	(Credential) Enter the OAuth client secret, created for your SAP Jam tenant (see **Prerequisites**).

Property Name	Description & Value
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your SAP Jam instance, in format: **`https://<SAP_Jam_datacenter>/api/v1/auth/token`** For example: *https://jam4.sapjam.com/api/v1/auth/token*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Jam Collaboration* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Jam Collaboration. For more information, see:

   Manage Transformations [page 2439]

   SAP Business Accelerator Hub: SAP Jam Collaboration

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be

automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

1.6.3.32 SAP Market Communication for Utilities

Follow this procedure to set up SAP Market Communication for Utilities as a proxy system.

Prerequisites

- You have user credentials for an external back-end system with read and write permissions.
- To establish the connection between Identity Provisioning and SAP Market Communication for Utilities, you need to set up the communication user in SAP Market Communication for Utilities. You can do it now (as a prerequisite) or in the process of configuring SAP Market Communication for Utilities as a proxy system, as described in step 5.

Context

The SAP Market Communication for Utilities application is based on SAP BTP ABAP environment. You can use Identity Provisioning to configure SAP Market Communication for Utilities as a proxy system to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then continue executing CRUD operations back to SAP Market Communication for Utilities, whenever the external back-end requests such. This scenario supports:

- Reading of **business users** (Employee) and **business roles** (which are considered as *groups*)
- Writing of **users** and **assignments**

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Market Communication for Utilities* as a proxy system. For more information, see: Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP Market Communication for Utilities and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP Market Communication for Utilities proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection [page 2452].

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Market Communication for Utilities backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

      For more information, see Maintain a Communication Arrangement for Inbound Communication

> ### Note
>
> The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
>
> The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the API URL to your SAP Market Communication for Utilities system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.

Property Name	Description & Value
`maco.skip.read.archived`	In the event of archived (disabled) entities in your SAP Market Communication for Utilities system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd* (needed for the *Read Transformation*)
`maco.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Market Communication for Utilities proxy system in a hybrid scenario. • **true** – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties
(Optional) `maco.roles.filter`	Enter OData filtering for reading roles in the SAP Market Communication for Utilities system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**
(Optional) `maco.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP Market Communication for Utilities system. The value must be an integer number.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://12345-aaaaa-3333.abap.hana.ondemand.com
User=MyMaCoUser
Password=************
ips.date.variable.format=yyyy-MM-dd
maco.skip.read.archived=true
maco.user.roles.overwrite = false
maco.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
maco.roles.page.size=30
```

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Market Communication for Utilities* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Market Communication for Utilities system. For more information, see:

   Manage Transformations [page 2439]

   SAP S/4HANA Cloud API: Business User

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource in the *Read Transformation*. To learn how, see Guided Answers: Business Role Description.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ### Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.33 SAP Marketing Cloud

Follow this procedure to set up SAP Marketing Cloud as a proxy system.

Prerequisites

- You have user credentials for an external back-end system with read and write permissions.
- To establish the connection between Identity Provisioning and SAP Marketing Cloud, you need to set up the communication (user, system and arrangement) on SAP Marketing Cloud. You can do it now (as a prerequisite) or in the process of configuring SAP Marketing Cloud as a proxy system, as described in step 5.

Context

You can use SAP Marketing Cloud as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP Marketing Cloud, whenever the external back-end requests such. This scenario supports:

- Reading of **users** and **Business roles** (which are considered as *groups*)
- Writing of **users** and **assignments**

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.

2. Save your changes.
3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
4. Save your changes.

3. Add *SAP Marketing Cloud* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP Marketing Cloud and configure your authentication method (basic or certificate-based).

> ### Note
>
> We recommend that you use certificate-based authentication.

   a. In your newly added SAP Marketing Cloud proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP Marketing Cloud backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

      For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

   c. Create a communication system and assign the created user to the communication system.

      For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

   d. Create a communication arrangement with the created system.

      For your Identity Provisioning scenario, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

      > ### Note
      >
      > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
      >
      > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP Marketing Cloud system.
`ProxyType`	Enter: *Internet*

Property Name	Description & Value
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol ',' (comma) as it is not supported.
`marketing.cloud.skip.read.archived`	In the event of archived (disabled) entities in your SAP Marketing Cloud system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`ips.date.variable.format`	*yyyy-MM-dd* (needed for the *Read Transformation*)
`marketing.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP Marketing Cloud proxy system in a hybrid scenario. • **true** – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties

Property Name	Description & Value
(Optional) `marketing.cloud.roles.filter`	Enter OData filtering for reading roles in the SAP Marketing Cloud system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option**
(Optional) `marketing.cloud.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP Marketing Cloud system. The value must be an integer number.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://my1234567-api.s4hana.ondemand.com*

`User`=*MyMarketingCloudUser*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`marketing.skip.read.archived`=*true*

`marketing.cloud.user.roles.overwrite` = *false*

`marketing.cloud.roles.filter`=*startswith(ID, 'EMPLOYEE_LEVEL_3') eq true*

`marketing.cloud.roles.page.size`=*30*

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Marketing Cloud* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Marketing Cloud. For more information, see:

   Manage Transformations [page 2439]

   SAP Marketing Cloud API: Business User

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

Read Transformation	Write Transformation

<pre>"optional": true
}
]
}
}</pre>	

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource in the *Read Transformation*. To learn how, see Guided Answers: Business Role Description.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ### Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

To learn more, see: Proxy Systems [page 1343]

1.6.3.34 SAP Master Data Integration

Follow this procedure to set up SAP Master Data Integration (in short, MDI) as a proxy system.

Prerequisites

- You have created a tenant in a subaccount on SAP BTP, Cloud Foundry environment. You can create your own tenant (free of charge), or integrate with an existing one.
- You have created a service instance for MDI in the subaccount in order to connect a new system to your tenant and read user account information from it. To learn how, see: Creating Service Instances
- You have created a service key in this instance, which contains the necessary credentials to connect to the MDI service. Creating multiple service keys in the same service instance is not supported. To learn how, see: Creating service Instances

  → Tip

  The *serviceKey* payload provides you with the following properties that you will later need for your system configuration:

  - **uri** =`URL`
  - **uaa.url** = `OAuth2TokenServiceURL`
  - **uaa.clientid** = `User`
  - **clientsecret** = `Password`

Context

As part of SAP's data model and integration unification strategy, SAP BTP Integration Suite has *Master Data Integration* to enable a harmonized integration and distribution of different master data objects and data between SAP solutions. This includes master data for business partners, cost centers, and workforce data. Workforce data is provided for integration scenarios that need data from SAP SuccessFactors Employee Central or other core HR systems.

To learn more, see: Integrating SAP SuccessFactors Employee Central with SAP Master Data Integration

You can use MDI as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities via API requests sent by an external back-end system (such as SAP Identity Management or SAP IAG).

⚠ Restriction

This scenario supports only executing *read* (GET) operations from MDI to the external back-end system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Master Data Integration* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to the relevant integration application running in the relevant region of SAP BTP. See the **Prerequisites** section → *serviceKey* tip.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user that has access to the API of your MDI service. See the **Prerequisites** section → *serviceKey* tip.
`Password`	(Credential) Enter the password for this technical user. See the **Prerequisites** section → *serviceKey* tip.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. See the **Prerequisites** section → *serviceKey* tip.

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ### Note
>
> The Identity Provisioning implementation of the SCIM Proxy API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Master Data Integration* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your MDI proxy system. For more information, see:

   Manage Transformations [page 2439]

   Field Mapping Between Employee Central and SAP Master Data Integration

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Read Transformation	Write Transformation

      }
    ]
  }
}
```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be

automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

Related Information

SAP Community: The New Master Data Integration Service for SAP SuccessFactors

1.6.3.35 SAP Revenue Growth Management

Follow this procedure to set up SAP Revenue Growth Management as a proxy system.

Prerequisites

- You have created an SAP Revenue Growth Management consumer application in your SAP Cloud Identity Services tenant and defined a dependency to its API, as described in Configure Integration Between Applications. *UserImport* must be selected for the dependency *API*.
- You have generated API credentials for the consumer application, as described in Generate Credentials to Access the APIs of an Application.

Context

SAP Revenue Growth Management is an SAP BTP SaaS application that provides customers in the Consumer Products industry an easy way to efficiently create, monitor, and maintain account plans.

You can use Identity Provisioning to configure SAP Revenue Growth Management as a proxy system in hybrid scenarios. For example, when SAP Revenue Growth Management is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group back to the SAP Revenue Growth Management.

> **Note**
>
> Support for groups is intended for future use.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.

- For **Basic authentication**, proceed as follows:
    1. Add an administrator user of type **System** and configure the basic authentication method for this user.
       If you already have a technical user, skip this step.
    2. Save your changes.
    3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
    4. Save your changes.

3. Add *SAP Revenue Growth Management* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the base URL of your SAP Revenue Growth Management system's SCIM API, excluding any path information.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the client ID generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`Password`	(Credential) Enter the client secret generated when creating API credentials for the consumer application. For more information, see Generate Credentials to Access the APIs of an Application.
`rgm.userImport.api.dependency.name`	Enter the value of the dependency name used in the configuration of the SAP Revenue Growth Management consumer application, created in the SAP Cloud Identity Services tenant. It is used for access token retrieval from Identity Authentication. For more information, see Integrating Applications.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL.

Property Name	Description & Value
(Optional) `rgm.user.filter`	When specified, only those users matching the filter expression will be read. You can filter users by **`userName`**, **`emails[0].value`**, and **`externalId`**, according to the API syntax of SAP Revenue Growth Management. For example: • *userName eq "johnbrown" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName sw "J" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails.value eq "johnbrown@email.com" and externalId eq "c167254d-25fd-5fac-af32-0b8c35e0de27"* **Note** These combinations are valid for both 'or' and 'and' operators.
(Optional) `rgm.group.filter`	When specified, only those groups matching the filter expression will be read. For example: *urn:sap:cloud:scim:schemas:extension:custom:2.0:Group:name eq "ProjectTeam1" or "Students2018"*
(Optional) `rgm.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. Default value for proxy systems: *true*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Revenue Growth Management* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Revenue Growth Management. For more information, see:

Manage Transformations [page 2439]

SAP Revenue Growth Management SCIM API

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

SAP Revenue Growth Management

1.6.3.36 SAP Sales Cloud and SAP Service Cloud

Follow this procedure to set up SAP Sales Cloud and SAP Service Cloud, formerly known as *SAP Cloud for Customer* (in short, C4C), as a proxy system.

Prerequisites

To integrate SAP Sales Cloud and SAP Service Cloud with Identity Provisioning, you need to use SAP Cloud Integration (SAP CI). This service provides a package with integration flows (iFlows) for enabling the creation of users and assignment of users to groups via SCIM API in SAP Sales Cloud and SAP Service Cloud.

- To configure SAP Cloud Integration and SAP Sales Cloud and SAP Service Cloud, see: Identity Provisioning in SAP Cloud for Customer using System for Cross-Domain Identity Management (SCIM)
- To set up and use the *SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management* package, see: SAP Business Accelerator Hub: SAP Cloud for Customer Integration with Identity Provisioning via System for Cross-domain Identity Management

Context

SAP Sales Cloud and SAP Service Cloud is a cloud-based solution that helps customers manage day-to-day sales and service interactions by sending and receiving signals between front- and back-office solutions and providing a single view of the customer.

You can use Identity Provisioning to configure SAP Sales Cloud and SAP Service Cloud as a proxy system for integration with on-premise or cloud identity management systems that support SCIM 2.0 standard (for example, SAP Identity Management and SAP Cloud Identity Access Governance).

In this scenario Identity Provisioning acts as a proxy between SAP Sales Cloud and SAP Service Cloud and the on-premise or cloud system. Identity Provisioning exposes SAP Sales Cloud and SAP Service Cloud as a proxy system and connects it to the identity management system without making a direct connection between both systems. You can then provision users to the identity management system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Sales Cloud and SAP Service Cloud.

The cloud-based solution provides different APIs for integration with Identity Provisioning, leading to different connector versions for each API. Currently, the following connector versions are available: Version 1 (SOAP-based API), which is deprecated, Version 2 (SOAP-based API), Version 3 (SCIM 2.0 based API) and Version 4 (SCIM 2.0 based API), which is applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only.

Each connector version supports specific attribute mappings in transformations and requires particular properties. The latest version is set as the default.

Version 4 (Applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only)

When using connector version 4 (SCIM 2.0 based API), only users of type Employee are provisioned. This version introduces an enhanced SCIM API that no longer requires SAP Cloud Integration. It supports patch operations and provisioning of application-specific groups. In addition to pagination using `startIndex` and `count`, cursor-based pagination is also supported.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Sales Cloud and SAP Service Cloud* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter SAP Cloud Integration runtime URL. See: How to Get SAP Cloud Integration Runtime URL
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
`OAuth2TokenServiceURL`	Enter the URL to the access token provider service. For example: `https://<c4c_instance>/auth/token` SAP Sales Cloud and SAP Service Cloud support OAuth token-based authentication, enabling you to obtain an access token using either basic authentication (by setting User and Password) or certificate authentication. **Relevant for connector version 4**

Property Name	Description & Value
`User`	Enter SAP Cloud Integration user ID to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**
`Password`	(Credential) Enter SAP Cloud Integration password to connect to SAP Cloud Integration. See: • Setting Up Inbound HTTP Connections (with Basic Authentication), Neo Environment • Basic Authentication of IdP User for Integration Flow Processing (Cloud Foundry environment) **Relevant for connector version 3**
`c4c.api.version`	The version of the SAP Sales Cloud and SAP Service Cloud API you use. By default, the Identity Provisioning service uses version **4** - the SCIM 2.0 based API.
(Optional) `c4c.user.filter`	When specified, only those users matching the filter expression will be read. Supported user filters in connector version 4: • userName eq "Smith" • userName sw "Sm" • userName eq "Smith" and emails.value eq "smith@example.com" Supported user filter in connector version 3: • addresses.country eq "USA"
(Optional) `c4c.group.filter`	When specified, only those C4C groups matching the filter expression will be read. Example: **displayName eq "ProjectTeam1"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> ### Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   The Identity Provisioning offers a default transformation for the *SAP Sales Cloud and SAP Service Cloud* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in C4C. For more information, see:

   Manage Transformations [page 2439]

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

   Default transformation for connector version 3

```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

1.6.3.37 SAP Signavio Process Transformation Suite

Follow this procedure to set up SAP Signavio Process Transformation Suite as a proxy system.

Prerequisites

> ⓘ Note
>
> The initial setup of SAP Signavio Process Transformation Suite is completed during the onboarding process. This setup includes establishing a connection between Identity Provisioning and SAP Signavio Process Transformation Suite using certificate-based authentication. Any changes needed after the initial setup should be processed through a support incident.

Context

SAP Signavio Process Transformation Suite helps you understand, improve, and transform your business processes – fast and at scale – with a cloud-based process management platform.

You can use Identity Provisioning to configure SAP Signavio Process Transformation Suite as a proxy system in hybrid scenarios. For example, when SAP Signavio Process Transformation Suite is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP Signavio Process Transformation Suite.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP Signavio Process Transformation Suite* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	The URL to the SCIM API of your SAP Signavio Process Transformation Suite system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`sig.tenant.id`	The identifier of SAP Signavio Process Transformation Suite tenant

Property Name	Value
(Optional) `sig.user.filter`	When specified, only those SAP Signavio Process Transformation Suite users matching the filter expression will be read. For example: • Value = *userName eq "JohnSmith"* • Value = *userName sw "J"*
(Optional) `sig.group.filter`	When specified, only those SAP Signavio Process Transformation Suite groups matching the filter expression will be read. For example: • Value = *displayName eq "ProjectTeam1"* • Value = *displayName sw "P"*
`sig.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to *true*, PATCH operations are used to update users and groups in the target system. • If set to *false*, PUT operations are used to update users and groups in the target system. **Possible values:** • *true* • *false* Default value: *false*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP Signavio Process Transformation Suite* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP Signavio Process Transformation Suite. For more information, see:

   Manage Transformations [page 2439]

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations:

Read Transformation

`}`	

> **Note**
>
> Updating a user in SAP Signavio Process Transformation Suite depends on whether user attributes in SAP Signavio Process Transformation Suite are mapped to SAML attributes in your identity provider. If this is the case, the values of those attributes are populated by the identity provider and cannot be changed by the SAP Signavio Process Transformation Suite SCIM API or the UI. For more information, see Map SAML Attributes to Users and Create a User.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > **Note**
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> **Caution**
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`

So make sure you use the correct domain when you construct your REST API requests.

For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

To learn more, see: Proxy Systems [page 1343]

1.6.3.38 SAP S/4HANA Cloud Public Edition

Follow this procedure to set up SAP S/4HANA Cloud Public Edition as a proxy system.

Prerequisites

- You have user credentials for an external back-end system with read and write permissions.
- To establish the connection between Identity Provisioning and SAP S/4HANA Cloud Public Edition, you need to set up the communication (user, system and arrangement) on SAP S/4HANA Cloud Public Edition. You can do it now (as a prerequisite) or in the process of configuring SAP S/4HANA Cloud Public Edition as a target system, as described in step 5.

Context

You can use SAP S/4HANA Cloud Public Edition as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP S/4HANA Cloud Public Edition, whenever the external back-end requests such.

SAP S/4HANA Cloud Public Edition provides different APIs for integration with Identity Provisioning, resulting in different connector versions for each API. Each connector version supports specific attribute mappings within the transformations and requires particular property values. The value of the `s4hana.cloud.api.version` property controls which API you use. By default, the Identity Provisioning service uses version *1*.

- When the value is set to *1* or the property is not present (typical for systems created before versioning was introduced on November 6, 2025), the SOAP API provided by the communication scenario SAP_COM_0193 is used. In SAP S/4HANA Cloud Public Edition version 1, groups correspond to business roles, thus group members are user assignments of a business role.
  In your SAP S/4HANA Cloud Public Edition system version 1, the HCM (HR) integration is active by default. You have **business users** (Employee, Contingent Worker) and **login users** assigned to them. The corresponding HR integration manages business users – it enables you to update these users from your external data source, such as an identity management system. The Identity Provisioning service manages only the user-related login information, such as date/time preferences or role assignments.
  This scenario supports:
  - Reading of **users** and **Business roles** (which are considered as *groups*)
  - Writing of **users** and **role assignments**

- When the value is set to *3*, the SCIM interface provided by the communication scenario SAP_COM_0465 is used. It supports provisioning of **business users** with their **assignments** to groups of type **userGroup** and **authorization**. For more information, see Groups.

For more information on how to update to version *3*, see Update Connector Version [page 2424].

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP S/4HANA Cloud Public Edition* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP S/4HANA Cloud Public Edition and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP S/4HANA Cloud Public Edition proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip step **a.** if you want to use basic authentication.

      The next steps are performed in SAP S/4HANA backend system and are relevant for both basic and certificate-based authentication.

   b. Create a communication user and provide the respective credentials.

      For basic authentication, provide *User Name* and *Password*.

For certificate-based authentication, upload the certificate you have generated in the Identity Provisioning UI on the previous step.

c. Create a communication system and assign the created user to the communication system.

For your Identity Provisioning scenario, provide *System ID*, *System Name* and *Host Name*.

d. Create a communication arrangement with the created system.

- When `s4hana.cloud.api.version=1` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition proxy system, choose *Scenario ID* SAP_COM_0193 (SAP Cloud Identity Provisioning Integration).

  > **Note**
  >
  > The communication scenario *SAP_COM_0193* is enhanced to support the User UUID attribute which is generated by Identity Authentication at user creation.
  >
  > The User UUID is universally unique identifier. This attribute is immutable and unique across technology layers, such as user interface, APIs, and security tokens, as well as across products and lines of business contributing to a business process in the Intelligent Enterprise.

- When `s4hana.cloud.api.version=3` is set in Identity Provisioning for the SAP S/4HANA Cloud Public Edition proxy system, choose *Scenario ID* SAP_COM_0465 (System for Cross-domain Identity Management Integration).

  > **Note**
  >
  > The communication scenario *SAP_COM_0465* allows you to maintain data via SCIM (System for Cross-domain Identity Management). For more information, see Integrate Cross-Domain Identity Management.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
URL	Enter the SAP S/4HANA Cloud Public Edition API URL. You can find the correct URL in the *API-URL* field of the communication arrangement set up for the communication scenario used. For example: `https://my123456-api.s4hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*

Property Name	Description & Value
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *User Name* from the communication arrangement. **⚠ Restriction** Do not use special symbol '**,**' (comma) as it is not supported.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the *Password* for the user name from the communication arrangement. **⚠ Restriction** Do not use special symbol '**,**' (comma) as it is not supported.
`s4hana.cloud.api.version`	The version of the system API you use. By default, Identity Provisioning uses version *1*. Version *1* means your SAP S/4HANA Cloud Public Edition system consumes SAP S/4HANA Cloud Public Edition API: Business User. Version *3* means your SAP S/4HANA Cloud Public Edition system consumes System for Cross-domain Identity Management (SCIM) API.
`s4hana.cloud.skip.read.archived`	In the event of archived (disabled) entities in your SAP S/4HANA Cloud Public Edition system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it. **Relevant for connector version 1**

Property Name	Description & Value
`s4hana.cloud.hr.switch.active`	Defines whether the human resources (HR) integration is active or not. The property is set to `true` by default. This means that the synchronization of business partners is managed by the HR system and SAP S/4HANA Cloud Public Edition. When set to `false`, synchronization is handled by the identity management system instead. *Possible values*: • true (default) • false **Relevant for connector version 1**
`s4hana.cloud.hr.switch.dependent.role.codes`	A default property. As a comma-separated value, add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your *read* and *write* transformations. By default, the following codes are added to your system: **BUP003, BBP005**. That means, your HR integration will support *employees* and *contingent worker*. **Relevant for connector version 1**
`ips.date.variable.format`	*yyyy-MM-dd* (needed for the read transformation)
`s4hana.cloud.user.roles.overwrite`	This property defines whether the current roles of a user to be preserved or overwritten by the Identity Provisioning service within the SAP S/4HANA Cloud Public Edition proxy system in a hybrid scenario. • **true** – the current user roles will be deleted in the proxy system, and the user will be updated only with the roles provisioned by the service. • **false** – the current user roles will be preserved, and the new roles (if any) will be added for the relevant user in the proxy system. See also: Extended Explanation of the *user.roles.overwrite Properties **Relevant for connector version 1**

Property Name	Description & Value
(Optional) `s4hana.cloud.support.patch.operation`	This property controls how modified entities (users and groups) in the source system are updated in the target system. • If set to **true**, PATCH operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, only these changes will be provisioned and applied in the target system. • If set to **false**, PUT operations are used to update users and groups in the target system. This means, for example, that if a user attribute is modified or a group member is removed from a group, all user attributes and all group attributes are replaced in the target system, instead of updating only the modified ones. Default value: *false* **Relevant for connector version 3**
(Optional) `s4hana.cloud.roles.filter`	Enter OData filtering for reading roles in the S/4HANA system. To learn what criteria you can use, see: OData URI Conventions → **4.5 Filter System Query Option** **Relevant for connector version 1**
(Optional) `s4hana.cloud.group.filter`	When specified, only those SAP S/4HANA Cloud Public Edition groups matching the filter expression will be read. Supported operators: eq (equal), co (contains), and sw (starts with). **Possible values:**: • `displayName` • `externalId` • `urn:ietf:params:scim:schemas:extension:sap:2.0:Group:type` For more information, see List of Properties [page 80]. **Relevant for connector version 3**

Property Name	Description & Value
(Optional) `s4hana.cloud.user.filter`	When specified, only those SAP S/4HANA Cloud Public Edition users matching the filter expression will be read. You can filter users by **list of attributes** according to the API syntax of SAP S/4HANA Cloud Public Edition. You can set a single attribute or multiple ones as filter criteria. If you enter multiple attributes (using OR operator), the filter will search for any of them. Supported operators: eq (equal), ne (not equal), sw (starts with), ew (ends with) and co (contains) **Possible values:** • `userName` • `externalId` • `emails[0].value` For example: • *userName eq "johnbrown" and externalId eq "P000252"* • *userName sw "J" or externalId eq "P000252"* • *userName eq "johnbrown" and emails[0].value eq "johnbrown@email.com"* • *userName eq "johnbrown" and emails[0].value ne "johnbrown@email.com" or externalId eq "P000252"* **Note** These combinations are valid for both 'or' and 'and' operators. **Relevant for connector version 3**
(Optional) `s4hana.cloud.roles.page.size`	Indicate how many business roles (considered as *groups*) per page to be read from your SAP S/4HANA Cloud Public Edition system. The value must be an integer number. **Relevant for connector version 1**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://my1234567-api.s4hana.ondemand.com
User=MyS4HANAuser
Password=************
s4hana.cloud.api.version=1
ips.date.variable.format=yyyy-MM-dd
s4hana.skip.read.archived=true
s4hana.onprem.hr.switch.active=true
s4hana.cloud.roles.filter=startswith(ID, 'EMPLOYEE_LEVEL_3') eq true
s4hana.cloud.user.roles.overwrite = false
s4hana.onprem.hr.switch.dependent.role.codes=BUP003,BBP005
s4hana.cloud.roles.page.size=30
```

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA Cloud Public Edition* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP S/4HANA Cloud Public Edition. For more information, see:

   Manage Transformations [page 2439]

   SAP S/4HANA Cloud API: Business User

   System for Cross-domain Identity Management (SCIM)

   Integrate Cross-Domain Identity Management

   Default read and write transformations for connector version 1:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

By default, Identity Provisioning reads group IDs and members. If you want the service to also read group descriptions, you can add an extra mapping to the *"group"* resource in the *Read Transformation*. To learn how, see Guided Answers: Business Role Description.

Default read and write transformations for connector version 3:

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>

1.6.3.39 SAP S/4HANA for procurement planning

Follow this procedure to set up SAP S/4HANA for procurement planning as a proxy system.

Prerequisites

You have technical credentials for SAP S/4HANA for procurement planning. See: Onboadring

Context

SAP S/4HANA for procurement planning is a cloud-based solution designed to help you plan procurement activities with regard to the time schedule, as well as the investment planning of items based on a central bill of material.

You can use Identity Provisioning to configure SAP S/4HANA for procurement planning as a proxy system in hybrid scenarios. For example, when SAP S/4HANA for procurement planning is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP S/4HANA for procurement planning.

This scenario supports provisioning **users**.

> ⓘ Note
>
> SAP S/4HANA for procurement planning does not support groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.

4. Save your changes.

3. Add *SAP S/4HANA Procurement Planning* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SCIM API of your SAP S/4HANA for procurement planning system without path information. For example: `https://procplanning-api.cfapps.eu10.hana.ondemand.com`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the OAuth Client Id, created for your SAP S/4HANA for procurement planning system.
`Password`	Enter the OAuth Client Secret, created for your SAP S/4HANA for procurement planning system.
`OAuth2TokenServiceURL`	Enter the OAuth 2.0 Token Service URL. For example: **https://procplansecurity.authentication.eu10.hana.ondemand.com/oauth/token**
(Optional) `s4hana.pp.user.filter`	When specified, only those SAP S/4HANA for procurement planning users matching the filter expression will be read. Example: **name.familyName eq "Smith" and addresses.country eq "US"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default

transformation for the *SAP S/4HANA for procurement planningTransformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your SAP S/4HANA for procurement planning system. For more information, see:

Manage Transformations [page 2439].

SAP Business Accelerator Hub: SAP S/4HANA for Procurement Planning

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

<pre>"sourcePath": "$.active", "targetPath": "$.active" }] } }</pre>	

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

1.6.3.40 SAP S/4HANA On-Premise

Follow this procedure to set up SAP S/4HANA on-premise (also valid for SAP S/4HANA Cloud, private edition) as a proxy system.

Prerequisites

> **Note**
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have technical credentials (user and password) for an external back-end system with read and write permissions.
- You have technical credentials (user and password) for SAP S/4HANA on-premise.
- The SAP S/4HANA on-premise system is version **1809** or higher.
- You have configured your SOA Manager to directly call the following Web services:
  - **ManageBusinessUserIn**
  - **QueryBusinessUserIn**

  For more information, see: Setting Up SOA Manager.

Context

You can use SAP S/4HANA on-premise as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to as a proxy connector to execute SAP S/4HANA on-premise, whenever the external back-end requests such. This scenario supports:

- Reading of **users**

- Writing of **users**

SAP S/4HANA on-premise supports provisioning of users with *User UUID* attribute which is generated by Identity Authentication at user creation. The attribute mapping is handled by the default transformation of AS ABAP. Therefore, to provision a user with *User UUID* to or from S/4HANA on-premise, the user should first be provisioned to AS ABAP and then linked to its corresponding business user in S/4HANA on-premise. For more information, see: SAP Application Server ABAP [page 1424].

According to your use case, you can decide whether to use SAP S/4HANA on-premise with HR (human resources) integration active or not.

- System with HR integration – When the HR integration is active, business users in SAP S/4HANA on-premise are created and managed by the HR system. The Identity Provisioning service can manage only the user-related login information, such as date/time preferences, or role assignments.
  This means that once the business users are created in SAP S/4HANA on-premise, you need to provision the users to AS ABAP so that they are linked to the business users (employee, collaboration user, contingent worker, resource) via the *User_Assignment* attribute.
- System without HR integration – lean business users will be created after the provisioning job, and the AS ABAP users will be linked to them. The Identity Provisioning service manages the complete set of **business partners** and their relevant **business users**.

To enable HR integration, you need to specify the relevant property in the system configuration. See **step 7** from the procedure below.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Open the Cloud Connector to add an access control system mapping for **SAP S/4HANA On-Premise**. This is needed to allow the Identity Provisioning service to access SAP S/4HANA On-Premise as a back-end system on the intranet. To learn how, see: Configure Access Control (HTTP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.

4. Save your changes.

4. Add *SAP S/4HANA On-Premise* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to your SAP S/4HANA On-Premise system.
`ProxyType`	Enter: *OnPremise*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user for SAP S/4HANA On-Premise.
`Password`	(Credential) Enter the password for the SAP S/4HANA On-Premise technical user.
`s4hana.onprem.skip.read.archived`	In the event of archived (disabled) entities in a source SAP S/4HANA On-Premise system, choose whether the provisioning jobs to continue reading such entities or to skip them. This property is enabled by default. If you want to always read disabled entities, set the property to **false**, or delete it.
`s4hana.onprem.hr.switch.active`	This property is disabled by default. Possible values: • **true** – HR integration is enabled for your system • **false** (default value) – HR integration is disabled for your system
`s4hana.onprem.hr.switch.dependent.role.codes`	A default property. Relevant only for systems with activated HR integration, that is if `s4hana.onprem.hr.switch.active` = *true*. As a comma-separated value, add the codes of the roles maintained by the HR integration. Make sure these role codes are part of your *read* and *write* transformations. By default, the following codes are added to your system: **BUP003, BBP005, BUP012, WFM001**. That means, your HR integration will support *employees*, *contingent worker*, *collaboration user*, and *resource*.
`ips.date.variable.format`	*yyyy-MM-dd* (needed for the read transformation)

Property Name	Description & Value
(Optional) `s4hana.onprem.sap-client`	Use this property if you want to specify a particular AS ABAP client to use as the **sap-client** URL parameter. If this property is not specified, the URL will open your default AS ABAP client. To learn more, see: Specifying the Client For more information about **sap-client**, see: SAP URL Parameters
(Optional)`CloudConnectorLocationId`	Relevant when the `ProxyType` property is set to *OnPremise*. Use it in case your SAP Business Technology Platform account uses more than one Cloud Connector or when the Cloud Connector uses `LocationID`.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*OnPremise*

`URL`=*http://aaa777.myhost:1234*

`User`=*MYS4HANAUSER*

`Password`=**********

`ips.date.variable.format`=*yyyy-MM-dd*

`s4hana.onprem.skip.read.archived`=*true*

`s4hana.onprem.hr.switch.active`=*true*

`s4hana.onprem.hr.switch.dependent.role.codes` = *BUP003,BBP010,BBP005*

`s4hana.onprem.sap-client`=*101*

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP S/4HANA On-Premise* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP S/4HANA On-Premise. For more information, see:

   Manage Transformations [page 2439]

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

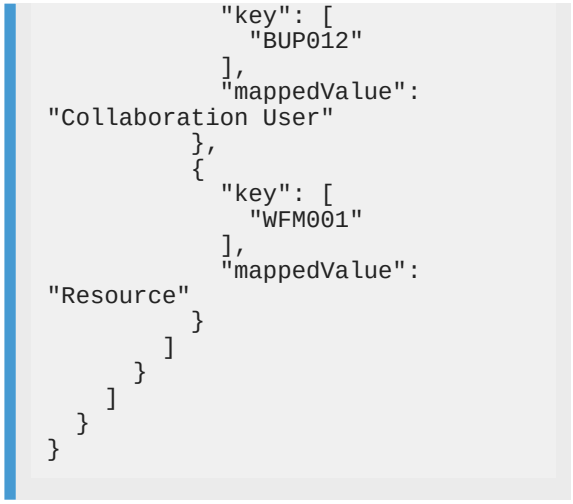
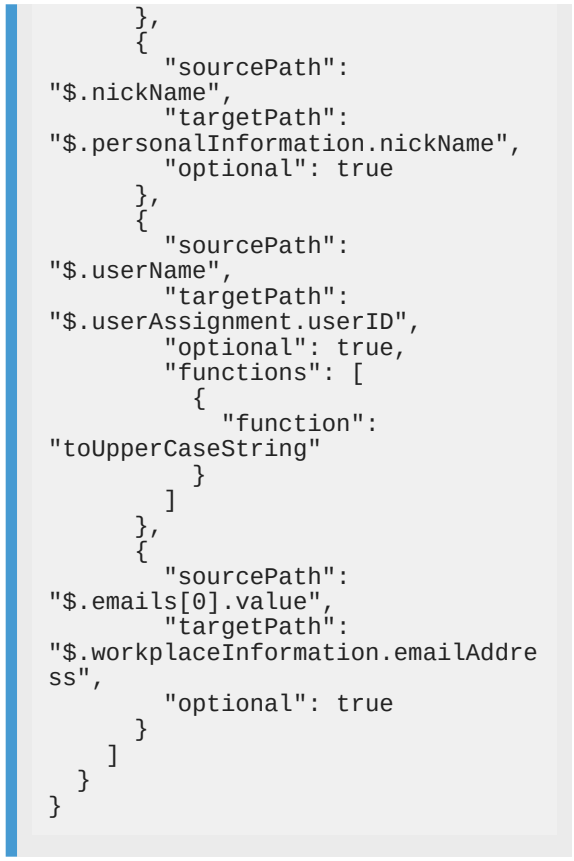
Read Transformation	Write Transformation
	




7. (Optional) If the external consumer system is **SAP Identity Management** (IDM), you can export the newly created proxy system as a *.csv* file. This will reduce the effort of manually entering all the properties again when an IDM administrator import the proxy configuration as a repository.

   To export the proxy system from the UI, choose *Export* > *CSV format*.

> → Tip
>
> When you import the *.csv* file as a SCIM repository in IDM, all the property fields will be automatically filled-in. However:
>
> - You have to manually enter your client ID and secret (AUTH_USER and AUTH_PASSWORD).
> - As currently the scenario does not support groups, you cannot make group assignments for users. Thus, for the SCIM_ASSIGNMENT_METHOD constant, remove the value (leave the field empty).

> ⓘ Note
>
> If you have purchased the Identity Provisioning service after **September 1, 2020**, for AUTH_USER and AUTH_PASSWORD, enter the technical user and password for which you have granted access to the Identity Provisioning Proxy API.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

SAP S/4HANA On-Premise
APIs for Business User Management
Maintain Collaboration Users

1.6.3.41 SAP SuccessFactors

Follow this procedure to set up SAP SuccessFactors as a proxy system.

Prerequisites

- You are using **SAP SuccessFactors HCM Suite OData API**
  You have created a technical user with permissions to **call** the SAP SuccessFactors HCM Suite OData API to **import** employee data into an SAP SuccessFactors system. For more information, see Permissions, Setting Up an API User for Sync Jobs in SAP SuccessFactors and URI Conventions (OData Version 2.0) .
- You are using **SAP SuccessFactors Workforce SCIM API**
  Consumers of the SAP SuccessFactors Workforce SCIM API can either create a technical user and assign the necessary permissions, or use the predefined technical user with built-in permissions for

communication between SAP SuccessFactors and Identity Provisioning using certificate authentication. For more information, see Upgrade to X.509 Certificate-Based Authentication for Incoming Calls and Permissions.

Context

You can use SAP SuccessFactors as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to SAP SuccessFactors, whenever the external back-end requests such.

SAP SuccessFactors provides two APIs for its integration with Identity Provisioning: SAP SuccessFactors HCM Suite OData API and SAP SuccessFactors Workforce SCIM API. The value of `sf.api.version` property controls which API you use.

- When the value is set to **`1`**, or the property is not defined - SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. This is the default value. SAP SuccessFactors source systems created before the introduction of `sf.api.version` property, use OData API. This version allows you to read users and groups, both static and dynamic. It also supports writing users, updating dynamic groups and group members.

  > ⚠ Restriction
  >
  > Note the following restrictions when using SAP SuccessFactors HCM Suite OData API:
  >
  > - You cannot *create* or *delete* groups as these operations are currently not supported.
  > - Managing SAP SuccessFactors **static groups** is not supported.

- When the value is set to **`2`** - SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used.
  This version allows you to provision static permission groups and user's group assignments. Provisioning of user's group assignments from a given external system to SAP SuccessFactors proxy system is possible if the user is an active employee with a work assignment.
  To update a group from the external system, a group with the same name should already exist in SAP SuccessFactors. For more information about the difference between static and dynamic groups in SAP SuccessFactors, see Permission Groups.

  > ⚠ Restriction
  >
  > Note the following restrictions when using SAP SuccessFactors Workforce SCIM API:
  >
  > - You cannot *create* or *delete* groups using the `Groups` APIs.
  > - The `Groups` patch API only supports updating membership of static permission groups.
  >
  > For more information, see Overview of SAP SuccessFactors Workforce System for Cross-Domain Identity Management API.

For more information on how to update to version 2, see Update Connector Version [page 2424].

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP SuccessFactors* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP SuccessFactors and configure your authentication method (basic or certificate-based).

   > **Note**
   >
   > We recommend that you use certificate-based authentication.

   a. In your newly added SAP SuccessFactors proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

      Skip this step if you use basic authentication. The next steps are performed in SAP SuccessFactors Admin Center and are relevant for certificate-based authentication only.

   b. Login to SAP SuccessFactors and go to *Admin Center*. Follow the procedure described in Upgrade to X.509 Certificate-Based Authentication for Incoming Calls.

      Make sure you select *Identity Provisioning Service* in the *Integration Name* field.
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
Type	Enter: *HTTP*

Property Name	Description & Value

URL	Specify the URL to your SAP SuccessFactors API.
	
	For example:
	• For version 1:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com/odata/v2`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com/odata/v2`**
	• For version 2:
	  • When *BasicAuthentication* is configured as authentication method: **`https://apitest.successfactors.com`**
	  • When *ClientCertificateAuthentication* is configured as authentication method: **`https://apitest.cert.successfactors.com`**
	
	To see the list of all SAP SuccessFactors data centers, see: SAP SuccessFactors API Reference Guide (OData V2): List of SAP SuccessFactors API Servers and System for Cross-domain Identity Management for Workforce in SuccessFactors

`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication*
(Optional) `sf.api.version`	Handles the version of the API which is consumed by the SAP SuccessFactors system. **Possible values:** • *1* - Indicates that SAP SuccessFactors HCM Suite OData API (in short, OData API) is used. • *2* - Indicates that SAP SuccessFactors Workforce SCIM API (in short, SCIM API) is used. Default value: *1*

Property Name	Description & Value
`User`	Valid if *BasicAuthentication* is configured as authentication method. Enter the *userID* of your SAP SuccessFactors technical user in the following format: **<user_ID>@<company_ID>**
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. Enter the password for your SAP SuccessFactors technical user.
`sf.company.id`	Valid if *ClientCertificateAuthentication* is configured as authentication method. Enter the Company ID of your SAP SuccessFactors system. The Company ID is a short string of characters that identifies each SAP SuccessFactors system. It is like a username for your organization. All users of the same system share the same Company ID.
`sf.user.attributes`	Default property. It's a string representing a comma-separated list of user attributes that have to be loaded (read) from SAP SuccessFactors. You can leave the default property value (all listed attributes), or leave only some of them. → Remember • Always make sure that attribute `lastModifiedDateTime` is in the list of values. If you don't specify it, the provisioning from SAP SuccessFactors will fail. • If a user in SAP SuccessFactors is missing this attribute, it will break the provisioning. You can exclude them from the provisioning (either by using the `sf.user.filter` property, or by setting a condition in the transformation logic). **Connector version**: SAP SuccessFactors version 1
(Optional) `sf.user.attributes.expand`	This property reads additional user data related to *complex attributes*, which are specified in `sf.user.attributes`. Default value: *personKeyNav* **Connector version**: SAP SuccessFactors version 1

Property Name	Description & Value
(Optional) `sf.user.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. Use this property to filter users from SAP SuccessFactors. The filter obtains values as described in the OData 2.0 syntax, except any statements with attribute `lastModifiedDateTime`. To learn more, see: • OData version 2 → **4.5. Filter System Query Option ($filter)**. • SAP SuccessFactors API Reference Guide (OData V2) • SAP SuccessFactors Workforce SCIM API and System for Cross-domain Identity Management for Workforce in SuccessFactors

Property Name	Description & Value
(Optional) `sf.user.read.deactivatedafter`	This property filters SAP SuccessFactors inactive users from a particular date on. It is an optional property which does not appear by default at system creation. It accepts a value in the **`yyyy-MM-dd`** format. For example: **`2023-07-17`** The `sf.user.read.deactivatedafter` property works together with the `sf.user.filter` property which is added at system creation with the default value: *active eq true*. Using it can further narrow down the filtering results. To filter active users along with inactive ones from a particular date on, the following configuration must be in place: • Set the `sf.user.read.deactivatedafter` value to a date in the expected format. For example: *2023-07-17* • `sf.user.filter` = *active eq true* As a result, Identity Provisioning reads SAP SuccessFactors active users and the users set to inactive from that date on using the 2023-07-17T00:00:00Z date-time format. Depending on the value you define for `sf.user.filter`, expect the following results: • `sf.user.filter` = *active eq false* All inactive users will be returned. • `sf.user.filter` = *active eq false and userName sw "Test_"* All inactive users with username starting with Test_ will be returned. **Note** When you filter by `sf.user.filter` = *active eq false* along with the property `sf.user.read.deactivatedafter`, the users that match the two critera will be read twice. • `sf.user.filter` = *active eq true and userName sw "Test_"* Inactive users from the provided date on and all active users with username starting with Test_ will be returned.

Property Name	Description & Value
	Connector version: SAP SuccessFactors version 2
(Optional) `sf.group.filter`	The possible values of this property depend on the API version which your SAP SuccessFactors system consumes. Use this property to filter dynamic groups in SAP SuccessFactors. The filter obtains values as described in the OData 2.0 syntax, except any statements with attribute `lastModifiedDateTime`. To learn more, see: • OData version 2 → **4.5. Filter System Query Option ($filter)** • SAP SuccessFactors API Reference Guide (OData V2) → **DynamicGroup** • SAP SuccessFactors Workforce SCIM API and System for Cross-domain Identity Management for Workforce in SuccessFactors
(Optional) `sf.page.size`	Defines the paging size. • Default value: **100** • Maximum value: **1000** **Connector version**: SAP SuccessFactors version 1
(Optional)`sf.group.members.paging.enabled`	This property enables paging of group members. The maximum number of group members returned per request is 100. To read more than 100 group members, paging must be enabled. **Possible values:** • *true* - Paging is enabled. • *false* - Paging is disabled. Default value: *true* **Connector version**: SAP SuccessFactors version 2

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination (configuration):

```
Type=HTTP
Authentication=BasicAuthentication
ProxyType=Internet
URL=https://apitest.successfactors.com/odata/v2
User=sfsf_admin@mycompany.com
Password=************
sf.user.attributes=userId,username,addressLine1,lastName,country,email,location,firstName,lastModifiedDateTime,personKeyNav,manager/username
sf.user.attributes.expand=personKeyNav,manager
sf.user.filter=department ne 'Manufacturing'
sf.group.filter=groupType eq 'permission'
sf.page.size=70
```

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors. For more information, see:

   Manage Transformations [page 2439]

   SAP SuccessFactors HCM Suite OData API

   SAP SuccessFactors Workforce SCIM API

   Default read and write transformations for SAP SuccessFactors HCM Suite OData API version 1:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external

application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

1.6.3.42 SAP SuccessFactors Employee Central Payroll

Follow this procedure to set up SAP SuccessFactors Employee Central Payroll as a proxy system.

Context

SAP SuccessFactors Employee Central Payroll is a cloud product for payroll processing. It's a service offering where SAP SuccessFactors Employee Central is used for maintenance of core HR master data and an SAP HCM Payroll system hosted in an SAP or Hyperscaler data center is used for payroll.

You can use Identity Provisioning to configure SAP SuccessFactors Employee Central Payroll as a proxy system in hybrid scenarios. For example, when SAP SuccessFactors Employee Central Payroll is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users back to the SAP SuccessFactors Employee Central Payroll.

This scenario supports provisioning users and groups.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP SuccessFactors Employee Central Payroll* as a proxy system. For more information, see Add New Systems [page 2415].
4. Set up the communication between Identity Provisioning and SAP SuccessFactors Employee Central Payroll and configure your authentication method (basic or certificate-based).

> **Note**
>
> We recommend that you use certificate-based authentication.

a. In your newly added SAP SuccessFactors Employee Central Payroll proxy system, select the *Certificate* tab and choose *Generate* > *Download*, as described in Generate and Manage Certificates for Outbound Connection.

   Skip step **a.** if you want to use basic authentication.

   The next step is performed in SAP SuccessFactors Employee Central Payroll backend system and is relevant for both basic and certificate-based authentication.

b. For certificate-based authentication, import the certificate generated in the Identity Provisioning UI in your SAP SuccessFactors Employee Central Payroll system, as described in Prerequisite: Finding the Access URL → step 5.

   For basic authentication, provide *User* and *Password*, as described in Prerequisite: Finding the Access URL → step 5.

c. Save your changes.

5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Enter the URL to your SAP SuccessFactors Employee Central Payroll system. For more information, see Prerequisite: Finding the Access URL → step 8.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter your authentication method: • *BasicAuthentication* • *ClientCertificateAuthentication* For more information, see Prerequisite: Finding the Access URL → step 5.
`User`	Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`Password`	(Credential) Valid if *BasicAuthentication* is configured as authentication method. For more information, see Prerequisite: Finding the Access URL → step 5.
`ecp.sap-client`	Enter the SAP client number (a three-digit number) of your SAP SuccessFactors Employee Central Payroll system. For example: **`102`**

Property Name	Value
(Optional) `ecp.user.filter`	When specified, only those SAP SuccessFactors Employee Central Payroll users matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *userName eq "JohnSmith"* • Value = *userName sw "J"* • Value = *emails.value eq "john.smith@example.com"*
(Optional) `ecp.group.filter`	When specified, only those SAP SuccessFactors Employee Central Payroll groups matching the filter expression will be read. Supported operators: eq (equal) and sw (starts with). For example: • Value = *displayName eq "ProjectTeam1"* • Value = *displayName sw "P"*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Employee Central PayrollTransformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Employee Central Payroll system. For more information, see:

   Manage Transformations [page 2439].

   Default read and write transformations:

   > **→ Tip**
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> **Note**
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> **Caution**
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>

Related Information

Identity Provisioning for Employee Central Payroll

1.6.3.43 SAP SuccessFactors Incentive Management

Follow this procedure to set up SAP SuccessFactors Incentive Management as a proxy system, formerly known as SAP Commissions.

Prerequisites

- You have technical user credentials for an SAP SuccessFactors Incentive Management system with read and write access permissions.

Context

Create a SCIM 2.0 proxy connector for SAP SuccessFactors Incentive Management to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the SAP SuccessFactors Incentive Management system, whenever the external back-end requests such. This scenario supports provisioning **users** and **user assignments to groups**.

> ⓘ Note
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.

3. Add *SAP SuccessFactors Incentive Management* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the SAP SuccessFactors Incentive Management SCIM API portal.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the user for your SAP SuccessFactors Incentive Management system.
`Password`	(Credential) Enter the password for your SAP SuccessFactors Incentive Management user.

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

   Exemplary destination:

   `Type`=*HTTP*

   `Authentication`=*BasicAuthentication*

   `ProxyType`=*Internet*

   `URL`=*https://mycommissions.callidus.run/CallidusPortal*

   `User`=*MyCommissionsUser*

   `Password`=**********

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Incentive Management* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Incentive Management. For more information, see:

   Manage Transformations [page 2439]

   SAP SuccessFactors Incentive Management REST API

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the

external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Related Information

SAP SuccessFactors Incentive Management: Integration with SAP IdP

1.6.3.44 SAP SuccessFactors Learning

Follow this procedure to set up SAP SuccessFactors Learning as a proxy system.

Prerequisites

You have created a technical user with administrator permissions that will be used to call the SAP SuccessFactors Learning API for provisioning user information.

Context

SAP SuccessFactors Learning is a learning solution which helps organizations to improve employee skills and talent management, align learning outcomes with performance goals, boost compliance, and train external audiences.

You can use the Identity Provisioning user interface (UI) to connect to SAP SuccessFactors Learning as a proxy system and configure it in hybrid scenarios. For example, when SAP SuccessFactors Learning is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups

to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and group members back to the SAP SuccessFactors Learning.

> ⚠ Restriction
>
> Provisioning **groups** is not supported.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *SAP SuccessFactors Learning* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the API of your SAP SuccessFactors Learning system. It follows the pattern: `https://<root URL>/learning/public-api/rest/admin/Integration.svc/ias`
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the technical user ID for SAP SuccessFactors Learning.

Property Name	Value
`Password`	(Credential) Enter the password for the SAP SuccessFactors Learning technical user. For more information, see Learning Technical User.
(Optional) `lms.user.filter`	When specified, only those users matching the filter expression will be read. **Possible values:** • *userName eq "testName"* • *externalID eq "testID"* • *active eq "true"* • *sourceSystem eq "Learning"* - indicates that the user is created directly in SAP SuccessFactors Learning with no involvement of Identity Provisioning. • *sourceSystem eq "Identity Provisioning"* - indicates that the user is created in SAP SuccessFactors Learning by Identity Provisioning.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users. For more information, see Query Parameters for Proxy System SCIM API.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SAP SuccessFactors Learning* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SAP SuccessFactors Learning system. For more information, see:

   Manage Transformations [page 2439].

   SAP Business Accelerator Hub: SAP SuccessFactors Learning

   Default read and write transformations:

   > **→ Tip**
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

        "scope": "patchEntity"
      }
    ]
  }
}
```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be

automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

- For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
- For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

> ⓘ Note
>
> For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*
>
> To learn more, see: Proxy Systems [page 1343]

1.6.3.45 Sales Cloud – Analytics & AI

Follow this procedure to set up Sales Cloud – Analytics & AI as a proxy system.

Prerequisites

- You have technical user credentials for an Sales Cloud Analytics & AI (in short, *SCAAI*) system with read and write access permissions.

Context

Create a SCIM 2.0 proxy connector for Sales Cloud – Analytics & AI to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the SCAAI system, whenever the external back end requests such. This scenario supports provisioning **users** and **user assignments to groups**.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *Sales Cloud – Analytics & AI* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
URL	Specify the URL to the SCIM API portal of your SCAAI system.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	Enter the user for your SCAAI system.
`Password`	(Credential) Enter the password for your SCAAI user.
`OAuth2TokenServiceURL`	Enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your SCAAI administrator.
(Optional)`sales.cloud.analytics_ai.group.filter`	Enter a group filter criteria, according to the API syntax of SCAAI. For example: **displayName eq "first_group"**
(Optional)`sales.cloud.analytics_ai.user.filter`	Enter a user filter criteria, according to the API syntax of SCAAI. For example: **externalId eq "John123"**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*http://myscaai:8080/scim_services*

`User`=*MySCAAIUser*

`Password`=**********

`OAuth2TokenServiceURL`=*http://myscaai:8080/gateway_services/api/auth/ips/token*

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Sales Cloud – Analytics & AI* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Sales Cloud – Analytics & AI. For more information, see Manage Transformations [page 2439].

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users**

or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

  }
```

Write Transformation

```
                "sourcePath":
"$.members[*].value",

"preserveArrayWithSingleElement":
true,
                "optional": true,
                "targetPath":
"$.members[?(@.value)]"
              }
        ],
        "scimEntityEndpoint":
"Groups"
    }
}
```

Read Transformation	Write Transformation
} 	

If you want the users and groups in SCAAI to have the **same** IDs as the respective users and groups in the external back-end system, modify the *Write Transformation* mappings as follows:

```
{
    "user": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.externalId"
            },
...
    "group": {
        "mappings": [
            {
                "sourcePath": "$.id",
                "targetPath": "$.externalId"
            },
...
}
```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PATCH**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PATCH** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>

1.6.3.46 Cloud Foundry UAA Server

Follow this procedure to set up the Cloud Foundry UAA server as a proxy system.

Prerequisites

> ⚠ Restriction
>
> This system is available for standalone tenants running on SAP Cloud Identity infrastructure and SAP BTP, Neo environment. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it only through **SAP Jam Collaboration** and **SAP Identity Access Governance** bundle options.

- You have a technical user with administrator permissions for Cloud Foundry UAA to read, create, and update user account information. You need Cloud Foundry UAA version **4.2** or higher.
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need to do this only if the Cloud Foundry UAA server is exposed in a private corporate network. For more information, see Cloud Connector.

Context

User Account and Authentication Service (UAA) is an OAuth2 server that you can use for centralized identity management. It owns the user accounts and authentication sources, and supports standard protocols (such as *SAML*, *LDAP*, and *OpenID Connect*) to provide SSO and delegated authorization to Web applications. For more information, see Cloud Foundry UAA: Overview .

Cloud Foundry UAA is responsible for the SAP ID service to create and manage platform users (platform administrators and platform developers) in Cloud Foundry.

→ Tip

This connector is meant for provisioning users and groups from/to **general** Cloud Foundry systems (they could be non-SAP ones). If you want to trigger provisioning of entities from/to SAP Business Technology Platform Cloud Foundry applications, you'd better use SAP BTP XS Advanced UAA (Cloud Foundry) [page 1516] proxy system.

These proxy systems consume SCIM 1.1 API provided by Cloud Foundry UAA.

→ Remember

You can manage users and groups to Cloud Foundry on **application** level only. You cannot manage them on a *subaccount* level.

ⓘ Note

The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Follow the steps below to create a SCIM 2.0 representation of your proxy Cloud Foundry UAA system. You can then provision on demand new users and groups back to Cloud Foundry UAA.

Procedure

1. (Optional) Open Cloud Connector to add an access control system mapping for the **Cloud Foundry UAA Server**. This is needed to allow the Identity Provisioning service to access the Cloud Foundry UAA system as a back-end system on the intranet. To learn how, see: Configure Access Control (HTTP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
4. Add *Cloud Foundry UAA Server* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the URL to the Cloud Foundry UAA SCIM API. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`OAuth2TokenServiceURL`	As you need to make OAuth authentication to the UAA system, enter the URL to the OAuth2 token service. If not sure about the exact URL, ask your Cloud Foundry UAA administrator.
`User`	Enter the OAuth client ID of the Cloud Foundry UAA technical user.
`Password`	(Credential) Enter the OAuth client secret of the technical user.
`uaa.origin`	Enter the location of your Cloud Foundry identity provider. If not sure about the value, ask your Cloud Foundry UAA administrator. The value of this property is a string, which will be used as the *origin* attribute in the system transformations.
`uaa.origin.filter.enabled`	This flag property depends on `uaa.origin`. Possible values: **true** or **false** • If set to *true*, the Identity Provisioning service will read only users whose identity provider is set as a value of `uaa.origin`. • If set to *false*, the Identity Provisioning service will read all users, regardless of their origin. • If set to *true* but the `uaa.origin` property is missing, the provisioning will fail.
`scim.support.patch.operation`	Use this property if you want to modify the members of a group. Possible values: • **true** – the Identity Provisioning service will modify the group membership via the *PATCH /Groups* endpoint of UAA. To learn how, see Patch • **false** – the Identity Provisioning service will modify the group membership via the *POST /Groups* or *DELETE /Groups* endpoints of UAA. To learn how, see Add Member and Remove Member .

Property Name	Description & Value
`uaa.patch.response.with.resource`	Use this property if you want to retrieve a group whose membership was modified. **Note** This property is usable only when you have configured membership modifications via *Add/Remove Member* UAA endpoints. That is, when the `scim.support.patch.operation` property is set to **false**. Possible values: • **true** – the Identity Provisioning service will return the modified group via the *GET /Groups* endpoint of UAA. To learn how, see Retrieve . • **false** – no modified groups will be returned by the service.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary destination:

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`ProxyType`=*Internet*

`URL`=*https://api.authentication.hana.ondemand.com*

`OAuth2TokenServiceURL`=*https://MyCFaccount.authentication.hana.ondemand.com/oauth/token*

`User`=*MyCFuser*

`Password`=**********

`uaa.origin`=*my_UAA_location*

`uaa.origin.filter.enabled`=*true*

`scim.support.patch.operation`=*true*

`uaa.patch.response.with.resource`=*false*

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Cloud Foundry UAA Server* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

You can change the default transformation mapping rules to reflect your current setup of entities in your Cloud Foundry UAA server. For more information, see:

Manage Transformations [page 2439]

Cloud Foundry UAA API: Users

Cloud Foundry UAA API: Groups

Default read and write transformations:

> → Tip
>
> The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
>
> The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
>
> However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation

is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

Cloud Foundry UAA: Users
Cloud Foundry UAA: Groups

1.6.3.47 Google G Suite

Follow this procedure to set up Google G Suite as a proxy system.

Prerequisites

1. Sign in to the Google API console (https://console.developers.google.com) and create a project.
2. Enable the Admin SDK. To do this, go to *Dashboard* > *ENABLE API* > *Admin SDK* > *ENABLE* .
3. Create a service account for your project. We recommend that you select *Enable G Suite Domain-wide Delegation* during the creation. If you skip this option, you can set it later. For more information, see Creating a service account .
4. Then, in the Google admin console (https://admin.google.com), a user with **Super Admin** role can delegate domain-wide authority to your service account. This way, it will have access to the Google Admin SDK on behalf of your user. For more information, see Delegating domain-wide authority .
   NOTE: When specifying the scopes, the administrator has to enter the following:
   `https://www.googleapis.com/auth/admin.directory.user, https://www.googleapis.com/auth/admin.directory.group`

Context

A Google service account with delegated domain-wide authority is required for authentication and authorization of the Identity Provisioning service to G Suite domain. The authentication is based on OAuth 2.0 protocol with JSON Web Token (JWT). The private key for the signature is distributed by Google via one-time downloadable JSON data, which is accessible by the domain administrator. The private key is encoded in PKCS8 format and is in the *private_key* field of the JSON data. For more information, see JSON Web Token (JWT) .

- When using it as a source system, you can read both users and groups from Google G Suite and provision them to any target system you have added in the Identity Provisioning user interface.
- When using it as a target system, you can write both users and groups, read from any source system you have added in the Identity Provisioning user interface. Google G Suite can automatically create accounts for your users in the Google Cloud Datastore.

The Identity Provisioning service supports user and group operations based on the following Google Directory API. See the table below.

User Operations	Group Operations
Create a user	Create a group
Retrieve a user	Retrieve a group's properties
Update a user	Update a group's properties
Delete a user	Delete a group

> ⚠ Caution
>
> You can only provision users whose e-mails are from verified domains.

If you have successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure below.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.

If you already have a technical user, skip this step.

2. Save your changes.
3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
4. Save your changes.

3. Add *Google G Suite* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Specify the service URL: **`https://www.googleapis.com/admin/directory`**
`ProxyType`	Enter: **`Internet`**
`Authentication`	Enter: *BasicAuthentication* The authentication type in use is actually **OAuth** with JWT. But for any provisioning system based on OAuth, **BasicAuthentication** is used along with the `OAuth2TokenServiceURL` additional property.
`User`	Enter the service account's ID. You can take it from the *"client_email"* field in the JSON data, downloaded during the setup of Google service account.
`Password`	(Credential) Enter the service account's private key, which represents a long string in PKCS8 format. You can take it from the *"private key"* field in the JSON data, downloaded during the setup of Google service account.
`OAuth2TokenServiceURL`	To make OAuth authentication to the Google G Suite system, enter the URL to the access token provider service. For more information, see Using OAuth 2.0 to Access Google APIs .
`jwt.subject`	Enter the Google G Suite user on behalf of which the Google Directory API is called. This user has been assigned the role **User Management Admin**. This property corresponds to "sub" claim in JWT being generated during access token request: JWT: "sub" (Subject) Claim
(Optional) `jwt.scope`	Enter space-separated Google Directory API authorization scopes. For example: **`https://www.googleapis.com/auth/admin.directory.user`**

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

Exemplary Configuration:

`ProxyType`=*Internet*

`Type`=*HTTP*

`Authentication`=*BasicAuthentication*

`URL`=*https://www.googleapis.com/admin/directory*

`User`=*1234567890-compute@developer.gserviceaccount.com*

`Password`=*-----BEGIN PRIVATE KEY-----\n123ABCDEFG123456789...*

... /123456789ABCDEFG123=\n-----END PRIVATE KEY-----\n

`OAuth2TokenServiceURL`=*https://www.googleapis.com/oauth2/v4/token*

`jwt.subject`=*john.smith@me123.accounts.ondemand.com*

`jwt.scope`=*https://www.googleapis.com/auth/admin.directory.user*

---

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Google G Suite* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   > ⚠ Caution
   >
   > An initial password setup is mandatory for all newly provisioned users. This is required by the Google G Suite API and must be provided when new accounts are created. The constant value that you see as configuration for the password attribute in the default transformation is generated by SAP. You have to change the constant value with another one, known only by the representatives of your company, before starting to use the Identity Provisioning service for creating users in your corporate Google G Suite system automatically.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Google G Suite. For more information, see:

   Manage Transformations [page 2439]

   Google Directory API: Users

   Google Directory API: Groups

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application

can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

                "type": "rename",
```

Read Transformation	Write Transformation
<pre>"targetPath": "$.members", "optional": true, "preserveArrayWithSingleElement": true }, { "targetPath": "$.members[*].status", "type": "remove" }, { "constant": "value", "targetPath": "$.members[*].id", "type": "rename" }, { "targetPath": "$.members[*].kind", "type": "remove" }, { "targetPath": "$.members[*].etag", "type": "remove" }, { "targetPath": "$.members[*].role", "type": "remove" }, { "constant": "display", "targetPath": "$.members[*].email", "type": "rename" }] } }</pre>	<pre>"constant": "id" }, { "targetPath": "$.members[*].display", "type": "remove" }] } }</pre>

If the **displayName** attribute in the source system transformation does not provide group e-mails, you can modify the transformation the following ways:

- Map **email** to another attribute that contains a unique group e-mail.
- Concatenate the **displayName** attribute with your domain. For example:

Sample Code

```
        {
            "sourcePath": "$.displayName",
            "targetPath": "$.email",
            "scope": "createEntity",
            "functions": [
                {
```

```
                    "type": "concatString",
                    "suffix": "@test.myaccount.ondemand.com"
                }
            ]
        }
```

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

1.6.3.48 LDAP Server

Follow this procedure to set up LDAP Server as a proxy system.

Prerequisites

> **Note**
>
> This system is available for all standalone tenants. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it as a proxy system for reading entities only.

> **Note**
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo) or Cloud Connector (Cloud Foundry)
- **For tenants running on the infrastructure of SAP Cloud Identity Services**: You have a multi-environment subaccount in the Cloud Foundry region that maps the region of your Identity Authentication tenant and it is subscribed to the *Cloud Identity Services* application. For more information, see Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.
- You have the credentials of a technical user in the LDAP Server, which is used to call the LDAP Server API to read and write users and their attributes.

Context

You can use LDAP Server as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the LDAP Server, whenever the external back-end requests such.

This scenario supports provisioning **users**, **groups** and **group assignments**.

There are two versions of the LDAP Server connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on May 25, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
  In this version, the `group members` attribute mapping in the proxy read transformation does not include `type` sub-attribute. In this case, all members are considered of type `User`, which is the sub-attribute fallback value. As a consequence, if the external system includes nested groups, they will not be handled properly.

- When the value is set to *2* – LDAP Server API version 2 is used.
  This version of the connector comes with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
  Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
  After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
  In this version, the `group members` attribute mapping in the proxy read transformation is enhanced with `type` sub-attribute. The sub-attribute has two possible values – `User` and `Group`. This allows you to read and preserve nested groups.
  For more information on how to update to LDAP Server connector version 2, see Update Connector Version [page 2424].

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Open Cloud Connector to add an access control system mapping for **LDAP Server**. This is needed to allow the Identity Provisioning service to access LDAP Server as a back-end system on the intranet. To learn how, see: Configure Access Control (LDAP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
4. Add *LDAP Server* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify the destination URL. It must be in the following format: `ldap://<external_host>:<external_port>`
`ldap.proxyType`	Enter: *OnPremise*
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.user`	Enter the *distinguishedName* of the technical LDAP user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the LDAP technical user.
`ldap.group.path`	Enter the complete path to the node containing the groups in the LDAP tree.
`ldap.user.path`	Enter the complete path to the users in the LDAP tree.
(Optional)`ldap.api.version`	Defines the version of LDAP Server API. **Possible values:** • **1** - Indicates that LDAP Server API version 1 is used. • **2** - Indicates that LDAP Server API version 2 is used. If the property is not defined - LDAP Server API version 1 is used.
(Optional) `ldap.group.filter`	You can optimize the search to return only particular groups. To enter correct group filters, stick to the standard LDAP specification. See: LDAP Representation of Filters – Examples . For example: Value *(cn=mar*)* will return only groups whose CN starts with "mar" (such as *marked*, *March*, or *Marketing*). By default, this filter is empty. That is, if the property is not specified, the filter will search for every group.

> → Remember
>
> We strongly recommend that you enter different paths for LDAP users and groups. That means, the value of `ldap.user.path` should be different than the value of `ldap.group.path`.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

The LDAP Server proxy system is created by default with the properties listed below:

Default LDAP Properties

`ldap.user.object.class=` **inetOrgPerson**

`ldap.group.object.class=` **groupOfNames**

`ldap.group.uniquename.attribute=` **cn**

`ldap.attribute.group.object.class.required=`**cn**

`ldap.attribute.user.object.class.required=`**cn**

`ldap.attribute.group.id=`**cn**

`ldap.attribute.group.member=` **member**

`ldap.attribute.user.id=` **uid**

`ldap.attribute.dn=`**distinguishedName**

`ldap.attribute.user.mail=` **mail**

`ldap.attribute.user.mobile=`**mobile**

`ldap.attribute.user.givenName=` **givenName**

`ldap.attribute.user.surname=` **sn**

`ldap.attribute.user.groups=` **memberOf**

`ldap.attribute.user.telephoneNumber=` **telephoneNumber**

`ldap.respond.with.resource.after.create=`**true**

`ldap.respond.with.resource.after.update=`**true**

> ### Note
>
> The **ldap.attribute.*** properties are used as parameterized properties in the default transformation. That is, if a property used in the transformation doesn't have a value, the provisioning job will fail when the transformation is loaded on runtime and the property value is substituted.
>
> Also, you can change a property and use a new one (with a new name). In this case, you must replace the old property with the new one at all corresponding places in the transformation.

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *LDAP Server* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your LDAP Server. For more information, see Manage Transformations [page 2439].

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations for LDAP Server connector version 1:

Read Transformation	Write Transformation

> **Note**
>
> By default, the **cn** attribute is used for every read or written group. An administrator can change this behavior by setting the following properties:
>
> - `ldap.group.uniquename.attribute` – the value can be either the CN or the whole DN (**distinguishedName**) of the group.
> - `ldap.attribute.group.id` – the value can be CN or another attribute to be used as a group ID instead (for example, **displayName** or **description**).

> For more information about these properties, see: List of Properties [page 80]

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Connection Pooling Configuration

1.6.3.49 Microsoft Active Directory

Follow this procedure to set up Microsoft Active Directory as a proxy system.

Prerequisites

> ### Note
>
> If you have purchased the Identity Provisioning service between **September 1, 2020** and **October 20, 2020**, and you want to make a connection to this on-premise system, follow the procedure in: Connect to On-Premise Systems in SAP Cloud Identity Infrastructure.

- You have installed the Cloud Connector in your corporate environment and have done the initial configuration. For more information, see: Cloud Connector (Neo)
- You have the credentials of a technical user in the Microsoft Active Directory, which is used to call the Microsoft Active Directory API to read and write users, groups and their attributes.

Context

You can use Microsoft Active Directory as a proxy connector to execute *hybrid* scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to Microsoft Active Directory, whenever the external back-end requests such.

This scenario supports provisioning **users**, **groups** and **group assignments**.

There are two versions of the Microsoft AD connector. Both consume the LDAP Server API to read and write users and groups. The versions are handled by the `ldap.api.version` property as follows:

- When the value is set to *1* or the property is not defined (typical for systems created before versioning was introduced on June 19, 2023) LDAP Server API version 1 is used. This is the default value of `ldap.api.version`.
  When using this version of the connector, the entities (users and groups) are read with all attributes.
  In this version, the `group members` attribute mapping in the proxy read transformation does not include `type` sub-attribute. In this case, all members are considered of type `User`, which is the sub-attribute fallback value. As a consequence, if the external system includes nested groups, they will not be handled properly.
- When the value is set to *2* – LDAP Server API version 2 is used.
  This version of the connector is with improved performance of the read operation for user and group attributes. You are now able to define which user and group attributes to be read. This is possible by adding values to the properties `ldap.user.attributes` or `ldap.group.attributes`.
  Via these properties, you are able to add also user and group operational attributes (attributes which the directory organizes for internal use). For more information, refer to the official LDAP server documentation.
  After the additional values of the properties are set, the default read or proxy read transformations should also be adjusted accordingly.
  In this version, the `group members` attribute mapping in the proxy read transformation is enhanced with `type` sub-attribute. The sub-attribute has two possible values – `User` and `Group`. This allows you to read and preserve nested groups.
  For more information on how to update to Microsoft Active Directory version 2, see Update Connector Version [page 2424].

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Open Cloud Connector to add an access control system mapping for **Microsoft Active Directory**. This is needed to allow the Identity Provisioning service to access Microsoft Active Directory as a back-end system on the intranet. To learn how, see: Configure Access Control (LDAP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators* .
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.

- For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
- For **Basic authentication**, proceed as follows:
    1. Add an administrator user of type **System** and configure the basic authentication method for this user.
       If you already have a technical user, skip this step.
    2. Save your changes.
    3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
    4. Save your changes.

4. Add *Microsoft Active Directory* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *LDAP*
`ldap.url`	Specify a destination URL. It must be in the following format: `ldap://<ext_host>:<ext_port>`
`ldap.proxyType`	Enter: *OnPremise*
`ldap.authentication`	Enter: *BasicAuthentication*
`ldap.user`	Enter the *distinguishedName* or the *userPrincipalName* of the Microsoft AD technical user. This is the user you need to establish the connection and to perform all queries.
`ldap.password`	(Credential) Enter the password for the Microsoft AD technical user.
`ldap.attribute.user.id`	Default property, which denotes the ID of a user. By default, it's set to: *cn*
`ldap.attribute.group.id`	Default property, which denotes the ID of a group. By default, it's set to: *cn*
`ldap.attribute.dn`	Default property, which denotes the distinguished name of a user or a group. Only possible value: *distinguishedName*
`ldap.respond.with.resource.after.create`	Default property, whose value is *true*.
`ldap.respond.with.resource.after.update`	Default property, whose value is *true*.
`ldap.group.path`	Enter the complete path to the node containing the groups in Microsoft Active Directory.

Property Name	Description & Value
`ldap.user.path`	Enter the complete path to the users in Microsoft Active Directory.
(Optional)`ldap.api.version`	Handles the version of the LDAP Server connector. **Possible values:** • *1* - Indicates that Microsoft AD API version 1 is used. • *2* - Indicates that Microsoft AD API version 2 is used. Default value: *1*
(Optional) `ldap.group.filter`	You can optimize the search to return only particular groups. To enter correct group filters, stick to the standard LDAP specification. See: LDAP Representation of Filters – Examples . For example: Value *(cn=mar*)* will return only groups whose CN starts with "mar" (such as *marked*, *March*, or *Marketing*). By default, this filter is empty. That is, if the property is not specified, the filter will search for every group.

Example for a destination or a set of properties:

```
Type=LDAP
Name=MyADDestination
ldap.user=john.smith@some.dummy.domain.com
ldap.password=********
ldap.attribute.user.id=cn
ldap.attribute.group.id=cn
ldap.attribute.dn=distinguishedName
ldap.url=ldap://abcd:123
ldap.proxyType=OnPremise
ldap.authentication=BasicAuthentication
ldap.group.path=OU=Groups,OU=IAS,DC=global,DC=corp,DC=mycompany
ldap.user.path=OU=Users,OU=IAS,DC=global,DC=corp,DC=mycompany
```

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Active Directory* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Microsoft AD. For more information, see:

   Manage Transformations [page 2439]

   Default read and write transformations:

   > → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Default read and write transformations for Microsoft AD connector version 1:

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

1.6.3.50 Microsoft Entra ID

Follow this procedure to set up Microsoft Entra ID (formerly known as Microsoft Azure Active Directory) as a proxy system.

Prerequisites

- You've logged on to Microsoft Azure Portal, with credentials for a user with directory role **Global administrator**. For more information, see Microsoft Entra built-in roles .

- In *Azure Active Directory* > *App registrations*, you've registered an application with a secret key and permissions for Microsoft Graph API. These permissions must be consented by an administrator. For more information, see Microsoft Graph permissions reference .
- (Relevant to target systems) Your registered application is assigned the **User Account Administrator** role. This role allows you to deprovision users. For more information, see Add-MsolRoleMember .

> **Note**
>
> If this role isn't assigned, you can only disable users. To do that, set the `accountEnabled` property to **false**. For more information, see MS Graph: user resource type

Permissions

Assign the following permissions to your application, according to your scenario. Also, the permissions have to be of type *Application*.

- Users – *User.ReadWrite.All*, *Directory.AccessAsUser.All*
- Groups – *Group.ReadWrite.All*

For more information, see MS Graph: Users and MS Graph: Groups

Context

When using it as a proxy system, you can write both users and groups, read from any source system you've added in the Identity Provisioning user interface. The Microsoft Entra ID proxy systems use Microsoft Graph API. For more information, see Microsoft Graph .

If you've successfully finished with the initial setup (described in the **Prerequisites** section), continue with the procedure.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.

- For **Basic authentication**, proceed as follows:
  1. Add an administrator user of type **System** and configure the basic authentication method for this user.
     If you already have a technical user, skip this step.
  2. Save your changes.
  3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
  4. Save your changes.

3. Add *Microsoft Entra ID* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter: **https://graph.microsoft.com**
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *BasicAuthentication*
`User`	Enter the application ID registered in your Microsoft Entra ID subscription (see the **Prerequisites** section).
`Password`	(Credential) Enter the secret key associated to your app registration.
`aad.domain.name`	Enter one of the verified domain names from the corresponding Microsoft Entra ID tenant. On this domain, you perform the provisioning operations. For more information, see Managing custom domain names in your Microsoft Entra ID .
`OAuth2TokenServiceURL`	Enter: **https://login.microsoftonline.com/<your_domain>/oauth2/token**, where `<your_domain>` is the domain name you have set in the **`aad.domain.name`** property.
(Optional) `aad.oauth2.resource.name`	Specifies the OAuth2 resource name for Microsoft Graph API. Enter: **https://graph.microsoft.com** You can change the Microsoft Graph endpoint to match your organization's cloud environment. For more information, see Microsoft Graph national cloud deployments.

Property Name	Description & Value
(Optional) `aad.group.member.attributes`	This property defines the attributes of a group member to be read by the Identity Provisioning. By default, it always reads the **type** and the **id** of a member. If you want the Identity Provisioning to read additional attributes, enter them as a single or a comma-separated value. For example: **Example** • If you want to read the e-mails too, enter: `aad.group.member.attributes=`*mail* This will read a member's type, ID, and e-mail. • If you want to read multiple additional attributes, enter: `aad.group.member.attributes=`*mail,mobilePhone,displayName* This will read a member's type, ID, e-mail, phone, and display name.
(Optional) `aad.user.attributes.membership.active`	Use this property if you want to get information about all the groups to which the users are assigned (if any). • If the property is missing, or is set to *false* – group membership details for the users will not be extracted. • If the property is set to *true* – group membership details for the users will be extracted. To learn more, see: List of Properties [page 80]
(Optional) `aad.user.filter`	Use this property to filter users by specific criteria, according to the Microsoft Graph REST API . **Note** This property replaces the deprecated `msgraph-filter` property. To learn more, see: List of Properties [page 80]
(Optional) `aad.group.filter`	Use this property to filter groups by specific criteria, according to the Microsoft Graph REST API .

Property Name	Description & Value
(Optional) `aad.user.filter.group.filter.combine`	Use this property to filter users based on their group assignments. When set to **true**, this property combines user and group filters defined on the `aad.user.filter` and `aad.group.filter` properties to further narrow the search results. This way, only users that meet the following filtering criteria are returned: • Users that match the user filter and at the same time are members of groups that match the group filter. • Members of the filtered groups that match the user filter. When set to **false**, user and group filters are not combined. To learn more, see: List of Properties [page 80]
(Optional) `aad.user.attributes`	Defines which user attributes are read from Microsoft Entra ID system. The property is set during system creation with the following default value: *id,mail,userPrincipalName,displayName,mailNickname,givenName,surname,mobilePhone,businessPhones* This means that by default, Identity Provisioning will read from Microsoft Entra ID the user attributes defined in the property value. Those attributes are used in the default read transformation. To check the complete set of user attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: User Properties To learn more, see: List of Properties [page 80]

Property Name	Description & Value
(Optional) `aad.group.attributes`	Defines which group attributes are read from Microsoft Entra ID system. The property is set during system creation with the following default value: *id,displayName,mailNickname* This means that by default, Identity Provisioning will read from Microsoft Entra ID the group attributes defined in the property value and will also return the *members* attribute. Those attributes are used in the default read transformation. To check the complete set of group attributes (properties) supported by Microsoft Entra ID, see: Microsoft Graph: Group Properties To learn more, see: List of Properties [page 80]
(Optional) `aad.entities.top`	This property defines the number of entities to be read per page. Default value: *100*
(Deprecated) `oauth.resource.name`	Enter: **https://graph.microsoft.com** **Note** The **oauth.resource.name** property has been deprecated, as it is no longer needed by the MS Entra ID connector. Use the **aad.oauth2.resource.name** property instead.

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. (Optional) Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Microsoft Entra ID* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Microsoft Entra ID. For more information, see:

   Manage Transformations [page 2439]

   MS Graph: Users

   MS Graph: Groups

   Default read and write transformations:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

Read Transformation	Write Transformation
	

Custom Configurations

Goal	Action	Result
You want Identity Provisioning to read the additional user attributes specified in property `aad.user.attributes` and write them successfully in the external back-end system.	In the *Read Transformation*, extend the "*user*" mapping as follows: `{ "user": { "condition": "$.userPrincipalName EMPTY false", "mappings": [ { "sourcePath": "$", "targetPath": "$" }, { "sourcePath": "$.id", "targetVariable": "entityIdSourceSystem" }, ...`	For example, you specify the `aad.user.attributes` property and set its value to: *id,mail,userPrincipalName,city,department,companyName* As a result, every user in the external back-end system will have the following attributes populated – ID, e-mail, user principle name, city, department, and company name. Returned information of an exemplary user: `... { "Resources":[ { "id":"555-aaaa-333-abcd-111222333", "mail":"john.smith@domain.com", "userPrincipalName":"abc@something.onmicrosoft.com", "city": "Sofia", "department":"029", "companyName":"SAP" } ... ] }`

Goal	Action	Result
You want Identity Provisioning to read the additional group attributes specified in property `aad.group.attributes` and write them successfully in the target system.	Extend the "*group*" mapping as follows: `{ "group": { "ignore": false, "mappings": [ { "sourcePath": "$", "targetPath": "$" }, { "constant": "urn:ietf:params:scim:schemas:core:2.0:Group", "targetPath": "$.schemas[0]" }, ...`	Example: Specify the `aad.group.attributes` property and set its value to: *id,displayName,recommendation,isSubscribedByMail* As a result, every group in the target system will have the following attributes populated – ID, display name, date and time of the last renewal, and information if it's subscribed by e-mail or not. Returned information of an exemplary group: `... { "Resources":[ { "id":"12345-ccc-000-xyz-777888999", "displayName":"ImportantGroup3", "renewedDateTime":"2018-01-01T00:00:00Z", "isSubscribedByMail":"true" } ... ] }`

Goal	Action	Result

You want the returned value of a group member to be not the ID but a different attribute.	Replace **id** with the new attribute. For example:
	If you replace *id* with *mail*, the transformation will look like this:
	`...`
	`{`
	`"sourcePath": "$.members",`
	`"preserveArrayWithSingleElement": true,`
	`"optional": true,`
	`"targetPath": "$.members"`
	`},`
	`{`
	`"targetPath": "$.members[*].mail",`
	`"constant": "value",`
	`"type": "rename",`
	`"optional": true`
	`}`
	`...`
	⚠ Caution
	Make sure that you've added this attribute as a value of property *aad.group.member.attributes*.
		Returned information of an exemplary group member:
		`...`
		`{`
		`"members":[`
		`{`
		`"id":"5555555-aaaa-333-abcd-1111122223333",`
		`"type":"user",`
		`"value":"johnsmith@mail.acme.com"`
		`}`
		`]`
		`}`
		`...`

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   ⓘ Note

   For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>

1.6.3.51 Procurement Data Warehouse

Follow this procedure to set up Procurement Data Warehouse as a proxy system.

Prerequisites

- You obtain credentials to access the Procurement Data Warehouse API.

  > ⓘ Note
  >
  > To obtain credentials to access the Procurement Data Warehouse API, create a case to the component *BNS-ARI-PRI*.
  >
  > In response to the case, SAP provides the certificate needed to access the API as well as the URL for the procurement data warehouse enrollment service, which is landscape-specific and starts with `*.cloud.sap`.

- You established trust between your SAP BTP subaccount and the SAP Cloud Identity Services - Identity Authentication service. For more information, see Establishing Trust Automatically.
- To configure your *Procurement Data Warehouse* provisioning system (see the procedure below), you will need to map your SAP Ariba application parameters to the relevant Identity Provisioning properties. The property mapping between the two systems is as follows:

Procurement Data Warehouse Application	Identity Provisioning	Values
API URL	`URL`	Examples: • US: **https://openapi.ariba.com** • Europe: **https://eu.openapi.ariba.com**
procurement data warehouseOAuth Token URL	`OAuth2TokenServiceURL`	Examples: • US: **https://api.ariba.com/v2/oauth/token** • Europe: **https://api-eu.ariba.com/v2/oauth/token**
OAuth Client ID	`client_id`	Enter the OAuth Client id used for access token retrieval.

- To load transaction data into procurement data warehouse, you must have one or more of the following SAP Ariba applications:
  - SAP Ariba Buying
  - SAP Ariba Buying and Invoicing
  - Guided sourcing capability for SAP Ariba Sourcing
  - SAP Ariba Contracts
  - SAP Ariba Spend Analysis

Context

The Procurement Data Warehouse is a capability that feeds analytics information from SAP Ariba applications, including guided sourcing capability for SAP Ariba Sourcing, SAP Ariba Buying and Invoicing, and SAP Spend Control Tower, to the embedded SAP Analytics Cloud. It provides data transfer, storage, loading, and reporting, and it drives visualization through advanced analytics dashboards.

You can use Identity Provisioning to configure Procurement Data Warehouse as a proxy system in hybrid scenarios. For example, when Procurement Data Warehouse is exposed as a proxy system, you can connect it to an external identity management system, such as SAP Identity Management, without making a direct connection between both systems. You can provision users and groups to the external backend system, which can trigger CRUD (create, read, update, delete) operations on users and groups back to the Procurement Data Warehouse.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
2. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
3. Add *Procurement Data Warehouse* as a proxy system. For more information, see Add New Systems [page 2415].
4. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Description & Value
`Type`	Enter: *HTTP*
`URL`	Enter the SAP Analytics Cloud URL for your Procurement Data Warehouse.
`ProxyType`	Enter: *Internet*
`Authentication`	Enter: *ClientCertificateAuthentication*
`client_id`	Enter the OAuth client id, generated for your Procurement Data Warehouse. (see the **Prerequisites** section)
`OAuth2TokenServiceURL`	Enter the URL of the access token provider service for your Procurement Data Warehouse instance. (see the **Prerequisites** section)
(Optional) `pdw.user.filter`	When specified, only those Procurement Data Warehouse users matching the filter expression will be read. For example: • *userName eq "Julie Armstrong"* • *userName sw "J"* • *emails eq "julie.armstrong@example.com"*

   To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

5. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *Procurement Data Warehouse* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your Procurement Data Warehouse. For more information, see:

   Manage Transformations [page 2439]

   > ### ⓘ Note
   >
   > To access the Procurement Data Warehouse API documentation, contact the Procurement Data Warehouse technical support.

   Default read and write transformations:

   > ### → Tip
   >
   > The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.
   >
   > The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.
   >
   > However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

6. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ### Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

7. Run an initial load job.

   If you try to provision groups that already exist in Procurement Data Warehouse proxy system, your provisioning job may fail with: '*The group already exists on the target system and cannot be provisioned*' error. This happens when you create a new proxy system and connect it to an existing Procurement Data Warehouse backend.

   To avoid this, you have the following options:

   - Delete the existing group in Procurement Data Warehouse proxy system.
   - Adapt the Procurement Data Warehouse write transformation. Either ignore provisioning of groups or add temporary the *skipOperations* expression for creating groups.
   - Avoid provisioning of already existing groups.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

> ⚠ Caution
>
> Effective **September 2020**, Shanghai (China) tenants that reside on SAP BTP, Neo can be only accessed on the following domain: `dispatcher.cn1.platform.sapcloud.cn`
>
> So make sure you use the correct domain when you construct your REST API requests.
>
> For example: **GET** *https://ipsproxyabcd12345-xyz789.dispatcher.cn1.platform.sapcloud.cn/ipsproxy/api/v1/scim/bbb111aa-1234-aaaa-7777-1234567abcde/Users/s123456789*

> To learn more, see: Proxy Systems [page 1343]

Related Information

Configure OAuth Certificate Authentication [page 2456]

1.6.3.52 SCIM System

Follow this procedure to set up SCIM as a proxy system.

Prerequisites

> ⓘ Note
>
> This system is available for all standalone tenants. Bundle tenants running on SAP Cloud Identity Services infrastructure and Neo environment can use it as a proxy system for reading entities only.

- You have technical user credentials for a SCIM system with read and write access permissions.
- (Optional) You have installed the Cloud Connector in your corporate environment and have done the initial configuration. You need this only if the SCIM system is exposed in a private corporate network. For more information, see Cloud Connector.

Context

Create a general SCIM 2.0 based proxy connector to execute hybrid scenarios. That means, it can provision its entities to another (external) back-end system by request, and then can continue executing CRUD operations back to the SCIM system, whenever the external back-end requests such. This scenario supports provisioning **users** and **groups**.

> **Note**
>
> The Identity Provisioning implementation of the Proxy System SCIM API (based on the SCIM Query) supports single entity and delta read filtering for users and groups. For more information, see Query Parameters for Proxy System SCIM API.

Procedure

1. (Optional) Open Cloud Connector to add an access control system mapping for the **SCIM system**. This is needed to allow the Identity Provisioning service to access the SCIM system as a back-end system on the intranet. To learn how, see: Configure Access Control (HTTP)
2. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Users & Authorizations* > *Administrators*.
3. Create a technical user with the necessary authorizations. It will later be used by the external consumer to connect to Identity Provisioning.
   - For **Certificate-based authentication**, upload the certificate for the technical user of type *System*, as described in Add System as Administrator and enable the *Access Proxy System API* permission.
   - For **Basic authentication**, proceed as follows:
     1. Add an administrator user of type **System** and configure the basic authentication method for this user.
        If you already have a technical user, skip this step.
     2. Save your changes.
     3. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
     4. Save your changes.
4. Add *SCIM System* as a proxy system. For more information, see Add New Systems [page 2415].
5. Choose the *Properties* tab to configure the connection settings for your system.

   Mandatory Properties

Property Name	Value
`Type`	Enter: *HTTP*
URL	Specify the service URL. For example: **`http://<cloudfoundry_server>.com/api/uaa/`**
`ProxyType`	Depending on your network exposure, enter one of the following: • *Internet* • *OnPremise*
`Authentication`	Enter: *BasicAuthentication*

Property Name	Value
`User`	You can specify one of the following: • Technical user ID • Client ID for OAuth HTTP destinations. It's used for retrieving of the access token.
`Password`	(Credential) You can enter one of the following: • Technical user password • Client secret for OAuth HTTP destinations. It's used for retrieving of the access token.
`OAuth2TokenServiceURL`	If you need to make OAuth authentication to the system, enter the URL to the access token provider service for OAuth HTTP destinations. For example: **`https://<token_provider>.com/api/oauth2/v2.0/token`**
`scim.csrf.token.path`	Specifies the path which is appended to the URL to retrieve the CSRF token when `scim.api.csrf.protection` is enabled.
`scim.api.csrf.protection`	Specifies whether to fetch a CSRF token when sending requests to the system. If enabled, this property requires the configuration of the `scim.csrf.token.path` property to specify the path where the CSRF token can be retrieved. **Possible values:** • *enabled* • *disabled*

To learn what additional properties are relevant to this system, see List of Properties [page 80]. You can use the main search, or filter properties by the *Name* or *System Type* columns.

6. Configure the transformations.

   Transformations are used to map the user attributes from the data model of the source system to the data model of the target system, and the other way around. The Identity Provisioning offers a default transformation for the *SCIM* proxy system, whose settings are displayed under the *Transformations* tab after saving its initial configuration.

   You can change the default transformation mapping rules to reflect your current setup of entities in your SCIM system. For more information, see Manage Transformations [page 2439].

   Default read and write transformation:

→ Tip

The proxy *Read Transformation* is used when the external client application (for example, SAP Identity Management) makes initial load. That is, executing GET requests to the resource endpoints (**/Users** or **/Groups**) to retrieve the corresponding entities of the particular type. The external client application can also execute GET requests to a single resource endpoint (querying a single resource is supported). In this case, the proxy system acts as a *source* one.

The proxy *Write Transformation* is used when the external application manages the entities in the proxy system – creates new entities, updates existing ones, or deletes existing ones. In this case, the proxy system acts as a *target* one.

However, after a *Create* or *Update* operation is performed on the proxy system, the *Read Transformation* is applied to the result, so that the created or updated entity is sent back to the external application. This behavior demonstrates that the proxy *Read Transformation* is used for *write* cases, as well.

            }
        ]
    }
}
```

7. Connect the external consumer to Identity Provisioning with the technical user you have created in step 2.

   If the external consumer system is **SAP Identity Management**, you can export the newly created proxy system as a SCIM repository from Identity Provisioning and import it in SAP Identity Management. This will create a SCIM repository in SAP Identity Management where most of the repository constants will be automatically filled in. You need to provide the technical user credentials that you have set up in step 2 and the SCIM assignment method as described below:

   - For AUTH_USER and AUTH_PASSWORD, enter the user ID and password of the Identity Authentication technical user for which you have set permission *Access Proxy System API*.
   - For the SCIM_ASSIGNMENT_METHOD constant, make sure the value is **PUT**.

   > ⓘ Note
   >
   > For external consumer systems, other than SAP Identity Management, you should also use the **PUT** method for modifying entities.

Next Steps

When a proxy system is connected to an external backend system (in the case of SAP Identity Management this means the exported CSV file is imported into the Identity Management Admin UI and a repository is configured), you can start managing the users and groups into this external system. Usually, the first operation is the initial load of the existing entities into your external system. When this load has finished, changes in the external system, such as creating new users or updating existing ones, can trigger CRUD requests back to the proxy system.

To see an example with SAP Identity Management, see Hybrid Scenario: SAP Identity Management [page 2961] → sections **Next Steps** and **Future Identity Lifecycle**.

1.7 Administration

The SAP Cloud Identity Services administration and configuration tasks are intended for administrators. They include configuring tenant settings, applications, authorization policies and provisioning, as well as managing users and groups, to ensure proper operations.For these configurations, administrators mainly use the administration console for SAP Cloud Identity Services, a Fiori-based user interface adaptive to most browsers.

Configuring Applications [page 1920]
: This section describes how you can configure the user authentication, access to an application, and use a branding style in accordance with your company requirements. It also explains the trust configuration between Identity Authentication and a service provider or client (relying party).

Configuring Tenant Settings [page 2100]
: Initially, the tenants are configured to use default settings. This section describes how you as a tenant administrator can make custom tenant configurations.

Configuring Password Policies [page 2223]
: Passwords for the authentication of users are subject to certain rules. These rules are defined in the password policy. Identity Authentication provides you with two predefined password policies, in addition to which you can create and configure up to three custom password policies.

Configuring Privacy Policies [page 2235]
: You can configure a custom privacy policy document by creating a new document, adding and editing its language versions, and defining the document for an application.

Configuring Authorization Policies [page 2244]
Authorization Management enables SAP Cloud Identity Services administrators to use authorization policies, customize them, and assign them to users.

Configuring Terms of Use [page 2273]
You can configure a custom terms of use document by creating a new document, adding and editing its language versions, and defining the document for an application.

Configuring Email Templates [page 2282]
Tenant administrators can use the default or a custom email template set for the application processes.

Managing Administrators [page 2301]
This section describes how, as a tenant administrator, you can list all administrators in the administration console for SAP Cloud Identity Services, add new administrators, and edit the administrator authorizations. You can also remove administrators.

Managing Technical Users [page 2329]
As a user with assigned special policy authorizations, you can manage the technical users in the administration console for SAP Cloud Identity Services.

Managing Agents [page 2333]
Agent identities automatically appear in SAP Cloud Identity Services after you deploy agents. You can use SAP Cloud Identity Services to review and manage access to these agents.

Managing Users [page 2342]
Tenant administrators can manage user accounts via the administration console for SAP Cloud Identity Services, and via APIs.

Managing Groups [page 2393]
Tenant administrators can create groups, and assign and unassign these groups to users via the administration console for SAP Cloud Identity Services.

Configuring Provisioning Systems [page 2413]
Configure provisioning systems for synchronizing users and groups between business applications.

Configuring Real-Time Provisioning [page 2487]
As a tenant administrator, you can configure real-time provisioning to immediately provision entities from source to target systems.

Configuring Social Identity Providers [page 2505]
By configuring a social provider, users can log on to applications with their social media credentials by linking their accounts in Identity Authentication to the social media account.

Integrating with Existing Customer Landscape [page 2518]
Identity Authentication can be integrated with already existing customer landscape and supports different types of delegated authentication.

Configuring External Authentication Providers [page 2620]
Configure authentication providers in the administration console for SAP Cloud Identity Services to manage users from external providers.

Configuring OpenID Connect (OIDC) [page 2636]
You can use Identity Authentication for authentication in OpenID Connect (OIDC) protected applications.

1.7.1 Configuring Applications

This section describes how you can configure the user authentication, access to an application, and use a branding style in accordance with your company requirements. It also explains the trust configuration between Identity Authentication and a service provider or client (relying party).

1.7.1.1 Create a New Application

You can create a new application and customize it to comply with your company requirements.

Context

You can create two types of applications in Identity Authentication:

> **Note**
>
> There are applications that show the `SAML 2.0 & OpenID Connect` protocol type. You can't create such applications.

Create SAML 2.0 Application [page 1923]
: You can create a new SAML 2.0 application and customize it to comply with your company requirements.

Create OpenID Connect (OIDC) Application [page 1925]
: You can create a new OpenID Connect (OIDC) application.

Related Information

Configure Trust [page 1941]
Configuring Applications [page 1920]

1.7.1.1.1 Create SAML 2.0 Application

You can create a new SAML 2.0 application and customize it to comply with your company requirements.

Context

To create a new SAML 2.0 application, you have to add a new application to the list of applications in Identity Authentication, and make sure that the protocol of the application is set to SAML 2.0.

To create a new SAML 2.0 application, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information and save your configuration:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they're created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the

Fields	Notes
	administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *SAML 2.0* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

Results

Once the application has been created, the system displays the message `Application <name of application> created`.

The newly created application appears on the list with the applications on the left. It is selected and you can proceed with its configuration.

Next Steps

1. Configure the SAML 2.0 trust with the service provider. For more information, see Configure SAML 2.0 Service Provider [page 1941].
2. (Optional) If necessary, configure the application. For more information about application configuration options, see Configuring Applications [page 1920].

Task overview: Create a New Application [page 1922]

Related Information

Create OpenID Connect (OIDC) Application [page 1925]

1.7.1.1.2 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.

3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are

Fields	Notes
	in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]

Task overview: Create a New Application [page 1922]

Related Information

Create SAML 2.0 Application [page 1923]

1.7.1.2 View Application Configurations

After creating the application, you can view its configuration settings.

Prerequisites

You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to view.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.

Results

The application configuration is displayed. Navigate through the tabs and list items in to check the different configuration settings of the application.

1.7.1.3 Edit Applications

After creating the application, you can change its display name, home URL, type and parent application.

Prerequisites

You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The *Display Name* is required. You can't leave that field empty.

The *Home URL* field is optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication. Initially, the *Home URL* for an application isn't configured in the administration console for SAP Cloud Identity Services. Once the *Home URL* has been set, you can change it.

> ### → Recommendation
>
> From a usability perspective we recommend you to use URL of a protected page.

> ### → Remember
>
> *Home URL* is necessary when you import new users in Identity Authentication. Identity Authentication needs to send activation emails to the new users and the home URL has to be mentioned in the emails. To access the application, the users have to activate their accounts. For more information see Import or Update Users for a Specific Application [page 2348].

The *Application Type* is optional. You can update the *Application Type* with one of the following:

Name Type	Application Type
SAP Analytics Cloud solution	`bundled`
SAP Ariba solution	`bundled`
SAP Business ByDesign solution	`bundled`
SAP BTP solution	`bundled`
SAP Central Business Configuration solution	`bundled`
SAP Concur solution	`bundled`
SAP Customer Data solution	`bundled`
SAP Data Custodian solution	`bundled`
SAP Datasphere solution	`bundled`
SAP Emarsys Customer Engagement solution	`bundled`
SAP Fieldglass solution	`bundled`
SAP Enable Now solution	`bundled`
SAP Industry Cloud Solution	`bundled`
SAP Integrated Business Planning solution	`bundled`
SAP Jam solution	`bundled`
SAP Marketing Cloud solution	`bundled`
SAP Sales Cloud and SAP Service Cloud solution	`bundled`
SAP Sales Cloud solution	`bundled`
SAP Signavio solution	`bundled`
SAP SuccessFactors solution	`bundled`
SAP S/4HANA Cloud solution	`bundled`
Other SAP cloud solution	`bundled`
SAP on-premise solution	`bundled`
Qualtrics solution	`bundled`
SAP LeanIX solution	`bundled`
SAP Business Data Cloud solution	`bundled`
Non-SAP solution	`charged`
Unknown	`charged`

→ Remember

You can't change the application type of the system applications.

Bundled SAP S/4 HANA Cloud and SAP Integrated Business Planning solutions are managed and configured by SAP and can't be deleted. Part of their SAML 2.0 configurations are read-only. Be careful when you make configuration changes.

The *Parent Application* field is optional.

Changing child application's configuration doesn't affect the configuration of the parent.

Applications that have a parent application configured can't be selected as parent application.

An application that is chosen as a parent application to another can't have a parent application assigned for it.

→ Remember

An application that is chosen as a parent application to another cannot be deleted.

To edit the application configurations, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   ⓘ Note

   Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.

   If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Edit* button on the top right corner.
5. Edit the fields:

Field	Notes
Display Name	Required
Home URL	Optional
Type	Optional ⚠ Caution If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. • If you are an administrator with the *Manage Applications* role, the newly created applications can

Field	Notes
	have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325]. Existing applications that have a parent application assigned to them will inherit only the configurations that have not been changed, including the configurations that are made at the creation of the application. The configurations that are changed, and the configurations made at the creation of the application are not inherited. See the list below for the configurations made at the creation of the application: • Protocol • Subject Name Identifier **Note** When a subscribed application becomes a child application, the configuration of the `Subject Name Identifier` of that child application can be different from the parent application or from the application it is subscribed to. You can make the configuration of the `Subject Name Identifier` the same as the parent application by choosing the *Inherit from Parent* button on the top right-hand corner of the screen. You can also make the configuration of the `Subject Name Identifier` the same as the application it is subscribed to by choosing the *Reset* button on the top right-hand corner of the screen. Depending on your configuration, either the *Inherit from Parent* or the *Reset* button is active, or both buttons are active. • Default Name ID Format • Attributes

Field	Notes
	Note Attributes from different sources are inherited separately. For more information about the different user attribute sources, see User Attributes [page 1972]. • Dependencies • Risk-Based Authentication • Conditional Authentication • Email Verification • Password Policy • Terms Of Use • Privacy Policy • User Application Access • User Attributes for Access • Token Url Separator • Reload Parent Page **→ Tip** A child application can override all the configurations inherited from the parent application. If you change a configuration in the child that is inherited from the parent, and after that you decide to return to the inherited one, go to the respective configuration and choose the *Inherit from Parent* button on the top right-hand corner of the screen. **Caution** If you change a configuration in the child that is inherited from the parent, also change the name of the child, so that it differs from the name of the parent. Saving the configuration without changing the child application's name may result in failing authentication requests.
Organization ID	The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. **→ Remember** The field is visible to users assigned to application authorization policies, or with Manage Applications role.

Field	Notes
	For more information about the application authorization policies, see Configure Application Authorizations [page 2325]. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. By default all applications are in the `global` *Organization ID*. Enter a new name to change the value of *Organization ID*. **Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Choose from: • SAML 2.0 (default selection) • OpenID Connect **Note** There are applications that show the `SAML 2.0 & OpenID Connect` protocol type. You can't create such applications. **→ Remember** If you change the parent application, the child application will inherit the protocol from the new parent. To change the protocol, first finish the editing and then repeat the procedure again, this time changing the protocol.

6. Save your changes.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

1.7.1.4 Change an Application's Display Name

Prerequisites

You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Edit* button on the top right corner.
5. Change the name in the *Application Display Name* field in the dialog box that appears.
6. Save your changes.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

1.7.1.5 Configure an Application's Type

You can choose and set the *Application Type* in the administration console for SAP Cloud Identity Services.

Context

In some cases Identity Authentication can't determine the correct application type because, for example of unknown URL or custom domain. In such cases you can update the application type with one of the following:

Name Type	Application Type
SAP Analytics Cloud solution	`bundled`
SAP Ariba solution	`bundled`
SAP Business ByDesign solution	`bundled`
SAP BTP solution	`bundled`
SAP Central Business Configuration solution	`bundled`
SAP Concur solution	`bundled`
SAP Customer Data solution	`bundled`
SAP Data Custodian solution	`bundled`
SAP Datasphere solution	`bundled`

Name Type	Application Type
SAP Emarsys Customer Engagement solution	`bundled`
SAP Fieldglass solution	`bundled`
SAP Enable Now solution	`bundled`
SAP Industry Cloud Solution	`bundled`
SAP Integrated Business Planning solution	`bundled`
SAP Jam solution	`bundled`
SAP Marketing Cloud solution	`bundled`
SAP Sales Cloud and SAP Service Cloud solution	`bundled`
SAP Sales Cloud solution	`bundled`
SAP Signavio solution	`bundled`
SAP SuccessFactors solution	`bundled`
SAP S/4HANA Cloud solution	`bundled`
Other SAP cloud solution	`bundled`
SAP on-premise solution	`bundled`
Qualtrics solution	`bundled`
SAP LeanIX solution	`bundled`
SAP Business Data Cloud solution	`bundled`
Non-SAP solution	`charged`
Unknown	`charged`

> → Remember
>
> You can't change the application type of the system applications.
>
> Bundled SAP S/4 HANA Cloud and SAP Integrated Business Planning solutions are managed and configured by SAP and can't be deleted. Part of their SAML 2.0 configurations are read-only. Be careful when you make configuration changes.

To configure the *Application Type*, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Edit* button on the top-right corner.
5. Choose the correct type from the drop-down in the *Application Type* field in the dialog box that appears.

> ⚠ Caution
>
> If the type of the application is not the correct one, the system may change it automatically without a warning.

6. Save your changes.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Related Information

1.7.1.6 Configure an Application's Home URL

You can configure the *Home URL* of an application in the administration console for SAP Cloud Identity Services.

Context

Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication. Initially, the *Home URL* for an application is not configured in the administration console for SAP Cloud Identity Services. Once the *Home URL* has been set, you can change it.

> → Recommendation
>
> From a usability perspective we recommend you to use URL of a protected page.

> → Remember
>
> *Home URL* is necessary when you import new users in Identity Authentication. Identity Authentication needs to send activation emails to the new users and the home URL has to be mentioned in the e-mails.

To access the application, the users have to activate their accounts. For more information see Import or Update Users for a Specific Application [page 2348].

To configure the *Home URL*, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Edit* button on the top right corner.
5. Type the address in the *Application Home URL* field in the dialog box that appears.

   > → Tip
   >
   > From a usability perspective we recommend you to use URL for a protected page.

6. Save your changes.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Related Information

Invitation REST API [page 2802]
User Registration [page 2807]

1.7.1.7 Visit an Application's Web Page

You can navigate to an application's Web site directly from the administration console for SAP Cloud Identity Services.

Prerequisites

You have configured *Home URL* for the application in question. For more information, see Related Information.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Select the *Home URL* anchor text.

   The Web page for the application opens in a new window.

Related Information

Configure an Application's Home URL [page 1937]
Create a New Application [page 1922]

1.7.1.8 Delete Applications

As a tenant administrator, you can delete one or more charged or bundled applications in a tenant of Identity Authentication.

Prerequisites

- You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have at least one bundled or charged application that you want to delete.

Context

A *Delete Applications* operation removes the application and all of its configurations from the tenant of Identity Authentication.

> ⓘ Note
>
> You can only delete charged or non-SAP managed bundled applications. The system applications and the bundled applications that are managed and configured by SAP cannot be deleted. For more information, see Application Types [page 63] and Configure an Application's Type [page 1935].

Follow the procedure below for each application that you want to delete:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Select the application that you want to delete.

   > → Tip
   >
   > Type the name of the application in the search field to filter the list items.

4. Choose the *Delete* button in the right-hand panel to delete the selected application.
5. Confirm the operation in the pop-up dialog.

   Once the application has been deleted, the system displays the message `Application <application name> deleted`.

1.7.1.9 Configure Trust

This document is intended to help you configure a trusted service provider (SP) or client (relying party) in the administration console for SAP Cloud Identity Services.

Context

The trust is configured by uploading the service provider metadata (for the SAML 2.0 applications), or by entering the information manually (for the SAML 2.0 or OpenID Connect applications). Depending on the SSO type, you can configure a SAML 2.0 trusted service provider or Open ID Connect trusted client in the administration console for SAP Cloud Identity Services:

Configure SAML 2.0 Service Provider [page 1941]
: This document is intended to help you configure a SAML 2.0 service provider (SP) in the administration console for SAP Cloud Identity Services.

Configure OpenID Connect (OIDC) Application [page 1949]
: This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services.

1.7.1.9.1 Configure SAML 2.0 Service Provider

This document is intended to help you configure a SAML 2.0 service provider (SP) in the administration console for SAP Cloud Identity Services.

Context

The trust is configured from the service provider metadata by uploading it or by accessing it from a URL, or by entering the information manually.

You can enter manually the name of the service provider, its endpoints, and certificates.

To configure the SAML 2.0 settings in the administration console for SAP Cloud Identity Services, choose the following options:

Make a New Trust Configuration [page 1942]
: Configure trust from the service provider metadata by uploading it or by accessing it from a URL, or by entering the information manually.

Configure Signing Certificates and Certificate Options [page 1946]
: You can add up to two signing certificates per application in the administration console for Cloud Identity Services.

Task overview: Configure Trust [page 1941]

Related Information

Configure OpenID Connect (OIDC) Application [page 1949]

1.7.1.9.1.1 Make a New Trust Configuration

Configure trust from the service provider metadata by uploading it or by accessing it from a URL, or by entering the information manually.

Prerequisites

You have the service provider metadata. See the service provider documentation for more information or contact the administrator of the service provider.

→ Tip

For more information how to download the metadata for SAP BTP when it acts as a service provider (SP), see Application Identity Provider. The content in this section is only relevant for SAP BTP Neo environment. The content in this section isn't relevant for China (Shanghai) region.

→ Remember

If your scenario includes the enabling of the *Trust All Corporate Identity Providers* option in the administration console, the service provider metadata must contain the assertion consumer (ACS) endpoint that can process unsolicited SAML responses.

With SAP BTP, the endpoint is the URL of the application's protected page. This endpoint must be either set as a default ACS endpoint of the service provider in Identity Authentication, or chosen by its index when performing IdP-initiated SSO. For more information, see Configure IdP-Initiated SSO [page 2201].

✤ Example

```
<ns3:AssertionConsumerService index="1" isDefault="false"
Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://
<application URL>/protected.jsp"
/>
```

Context

The trust is configured from the service provider metadata by uploading it or by accessing it from a URL, or by entering the information manually. When the identity provider metadata is uploaded, or the metadata URL is used, the fields are populated with the parsed data from the XML file.

You can enter manually the name of the service provider and its endpoints.

> → Remember
>
> If your scenario includes the enabling of the *Trust All Corporate Identity Providers* option, the assertion consumer (ACS) endpoint with the URL of the application's protected page, and the index must be included in the service provider metadata.

To configure a SAML 2.0 trusted service provider in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *SAML 2.0 Configuration*.
6. Upload the service provider metadata XML file, use the metadata URL, or manually enter the communication settings negotiated between Identity Authentication and the service provider.
   - *Load from URL* - The URL with service provider metadata.

     > → Remember
     >
     > The SAML 2.0 metadata URL is required for the automatic renewal of the automatic renewal of the signing and encryption certificates of the application. When the metadata URL is provided, Identity Authentication will update automatically the expired encryption certificate, and the SAML 2.0 certificate during the first sign in attempt that fails due to the expired certificate.
     >
     > If you update the already provided metadata URL, the SAML configuration will be updated, too.

   - *Load from File* - The metadata file of the service provider.

     > ⓘ Note
     >
     > Use a file with an extension `.xml`.

   - *Configure Manually* - Add the entity ID of the service provider and configure the information in the *Endpoints* tab.

Tab	Description
Endpoints	The SP's endpoint URL that receives the response with the SAML assertion from Identity Authentication. The following options are possible: • *Single Sign-On* Choose *Create* and enter the allowed domain for browser flows. • *Single Logout* Choose *Add* and enter the SP's endpoint URL that receives the logout response or request (for a multiple SPs scenario) from Identity Authentication for the termination of all current sessions. This field has the following attributes: • *Binding* - specifies the SAML binding supported by the logout endpoint. • HTTP-POST • HTTP-REDIRECT • SOAP - The SOAP Endpoint is called only when the user password is changed. **Note** If you have configured a *Warning* concurrent user access option, you must also have a Single Logout Endpoints (SLO) URL with a SOAP binding added for the SAML 2.0 application. Otherwise if a user chooses to sign out and continue to new session, an SLO request for the old session won't be sent to the application. For more information, see Configure Concurrent User Access to the Application [page 2018]. • *URL* - specifies the location of the logout endpoint. • *Response URL* - (optional) specifies a different location to which logout response messages should be sent. • *URL for Principal Propagation* - URL is required for principal propagation scenarios to ABAP applications according to RFC 7522. For the proper URL consult the documentation of the providing application.

Tab	Description
	Note During authentication the ACS endpoint is provided with the request. Through the flow, Identity Authentication is removing the query attributes, and during the response it compares the ACS endpoint with what is configured in the SAML 2.0 configuration of the application. Identity Authentication is looking for an exact match and If there is no such match the authentication will fail.

Restriction

The *Metadata URL*, *Entity ID*, and *Single Logout Endpoint* fields are not editable for the system applications.

Next Steps

Configure trust on the service provider side.

1. Download the SAML 2.0 metadata of Identity Authentication.

   Note

   For more information about how to download the SAML 2.0 metadata describing Identity Authentication as identity provider see Tenant SAML 2.0 Configurations [page 2103].

2. Configure the service provider to trust Identity Authentication.

   Note

   See the service provider documentation for more information about how to configure the trust.

   Tip

   If you use SAP BTP as a service provider, see Integrating the Service with SAP Business Technology Platform, Neo Environment [page 2910].

   The content in this section is only relevant for SAP BTP Neo environment.

   The content in this section is not relevant for China (Shanghai) region.

3. Configure the certificates in the administration console for Cloud Identity Services. For more information, see Configure Signing Certificates and Certificate Options [page 1946].

Task overview: Configure SAML 2.0 Service Provider [page 1941]

Related Information

Configure Signing Certificates and Certificate Options [page 1946]

1.7.1.9.1.2 Configure Signing Certificates and Certificate Options

You can add up to two signing certificates per application in the administration console for Cloud Identity Services.

Context

You can add up to two signing certificates. Both signing certificates are accepted according to the certificate validity.

You can choose the identity provider certificate to be used for signing for each application. For more information about the identity provider certificates, see Tenant SAML 2.0 Configurations [page 2103].

The idea behind the ability to choose the IdP certificate is that when you want to change the default IdP certificate all applications will have downtime since the applications have trust with the current default application on the application side. So, when adding new IdP certificate you can change the applications one by one to trust the new certificate.

> → Tip
>
> You can download the tenant metadata with the specific identity provider (IdP) certificate for the application by choosing the *Download Metadata File* button.

To configure signing certificates and certificate options in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *SAML 2.0 Configuration* > *Certificates*.
6. Under *Signing Certificate*, choose *Add* to add a base64-encoded certificate used by the identity provider to verify the signatures of the SAML protocol messages created by the service provider.

> **Note**
>
> If you have two certificates, you can choose a default one, to mark your primary certificate.
>
> The primary certificate is always validated first. If its validation isn't successful, then the secondary certificate is used. The certificate marked as primary is your main certificate. When it's time to rotate the certificates we recommend you to add a second certificate. When the first certificate expires, and you have a second one, you can safely remove the first one.

7. **Optional:** Under *Signing Options*, choose *Edit* and after that *Save* to configure the signing options for the application. You have the following possibilities:

Option	Default Configuration
Signing Algorithm	Select the digest algorithm for signing outgoing messages from the dropdown list. • *SHA-1* • *SHA-256* - the default option (for applications created after Jun 28, 2021) • *SHA-512*
Sign assertions	*On*
Sign authentication responses	*Off*
Sign single logout messages	*On*
Require signed authentication requests	*Off*
Require signed single logout messages	*On*

8. **Optional:** Under *Encryption Certificate*, add a certificate, if there is no encryption certificates added or you want to add a new certificate.
    a. Choose *Add*.
    b. Provide a file with extension `.crt` or `cer`, or insert the certificate as text.
    c. Choose *Add*.
9. **Optional:** (Visible only if there is and encryption certificate) Under *Encryption Option*, choose *Edit* to configure the encryption of the SAML 2.0 response
    a. Choose the elements to encrypt from the drop-down:
        - *None* - the default option
        - *Whole Assertion*
        - *Subject Name ID*
        - *Subject Name ID and Attributes*
        - *Attributes*

        The method for encryption is `aes-128-cbc`.
    b. Choose *Save*.

10. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *SAML 2.0 Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. **→ Tip** To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *Identity Provider Certificates* > *+Add*. **⚠ Caution** The application will stop working if the configuration of the application is not updated with the new certificate. **ⓘ Note** Your choice of *Active* certificate in the list isn't related to the choice of the *Default* certificate in *Tenant Settings* > *SAML 2.0 Configuration* > *SAML 2.0* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for SAML 2.0 Applications [page 2111].

→ Recommendation

When the default identity provider certificate is changed with a new one, and the old one isn't used anymore, we recommend you to delete the old certificate.

11. Save your selection.

    Once the application has been changed, the system displays the message `Application <name of application> updated`.

1.7.1.9.2.1 Configure OpenID Connect (OIDC) Application for Authorization Code Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the authorization code flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.

Setting	Description
Redirect URIs (mandatory)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Front-Channel Logout URIs	(Optional) URIs which will be requested for logout. You can add up to 20 URIs.
Back-Channel Logout URI	(Optional) URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the following grant types:

Grant Type	Notes
Authorization Code	For the authorization code flow.
Authorization Code > *Authorization Code / Enforce PKCE (S256)*	For the authorization code flow with PKCE.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> ⓘ Note
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

1.7.1.9.2.2 Configure OpenID Connect (OIDC) Application for Client Credentials Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the client credentials flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party).

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

→ Tip

When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

7. Select the *Client Credentials* grant type.

ⓘ Note

Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

8. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

→ Remember

Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

1. Configure authentication for the application. For more information about the configuration, see API Authentication [page 1996].

2. Invalidate the tokens that are no longer need. For more information, see Call Identity Authentication Revoke Token Endpoint [page 2736].

1.7.1.9.2.3 Configure OpenID Connect (OIDC) Application for Resource Owner Password Credentials Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the resource owner password credentials flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party).

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Under the *Configure Manually* section provide a name of your choice.
7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. **→ Tip** To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. **⚠ Caution** The application will stop working if the configuration of the application is not updated with the new certificate. **Note** Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> ### → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *Password*

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> ⓘ Note
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

1.7.1.9.2.4 Configure OpenID Connect Application for Implicit Flow

This document is intended to help you configure an OpenID Connect application in the administration console for SAP Cloud Identity Services for the implicit flow.

Prerequisites

You have an OpenID Connect application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.

Setting	Description
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Selct the *Implicit* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].

1.7.1.9.2.5 Configure OpenID Connect (OIDC) Application for JWT Bearer Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the JWT bearer flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

   > → Tip
   >
   > For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *JWT Bearer* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].

- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

  > **Note**
  >
  > The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

1.7.1.9.2.6 Configure OpenID Connect Application for Token Exchange

This document is intended to help you configure an OpenID Connect application in the administration console for SAP Cloud Identity Services for the Token Exchange flow.

Prerequisites

You have an OpenID Connect application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> ### → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list.

Option	Description
	→ Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *Token Exchange (RFC 8693)* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

1.7.1.10.1 Configure Authentication Context (SAML 2.0)

Tenant administrator can configure the authentication context in the request sent to the corporate identity providers when Identity Authentication acts as a proxy identity provider.

Context

> **Note**
>
> The following configuration is valid for SAML 2.0 corporate identity providers.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Trust* tab.
5. Under *Conditional Authentication*, choose *Configure Requests to Corporate Identity Providers* > *SAML 2.0*.
6. Choose one of the following options:
   - *None* - Authentication context isn't sent. The requested authentication context from the service provider is ignored.
   - *Service Provider Authentication Context* (Available only for SAML 2.0 applications) - The received authentication context from the service provider is sent.
   - *Password Protected Transport* - Authentication context class `urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport` is sent. The requested authentication context from the service provider is ignored.
7. Save your configuration.

1.7.1.10.2 Configure Authentication Context (OpenID Connect (OIDC))

Tenant administrator can configure the authentication context in the request sent to the corporate identity providers when Identity Authentication acts as a proxy identity provider.

Context

> **Note**
>
> The following configuration is valid for the OpenID Connect (OIDC) corporate identity providers.

The authentication context enables administrators to ensure an authentication context. For example, you can require the corporate identity provider to authenticate users for a particular application with multifactor authentication or certificate-based authentication. The corporate identity providers define what authentication contexts that they support as well as the values they require to trigger a particular authentication context. The OpenID Connect (OIDC) standard doesn't define the authentication context values.

For more information, see OpenID Connect Core 1.0 incorporating errata set 2 .

> **Tip**
>
> If the authentication context exists in the metadata of the identity provider it, can be seen in the administration console at *Identity Providers* > *Corporate Identity Providers* > *from the list - the corporate IdP that provides user authentication to the application* > *OpenID Connect (OIDC) Configuration* > *Supported Authentication Contexts section*.

> **Restriction**
>
> You can add up to 20 authentication context references with a length of up to 99 characters each.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.

3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Conditional Authentication*, choose *Configure Requests to Corporate Identity Providers* > *OpenID Connect (OIDC)*.
6. Choose *Add* > *enter the authentication context class references* > *save your changes*.

Results

The application sends the configured ACRs (authentication context references) to the corporate identity provider as part of the authorization request. These values are included in the `acr_values` query parameter and are separated by spaces ( ). You can see this parameter in the network trace of your browser.

Configure Authentication Context (SAML 2.0) [page 1967]
Configure Different Trust Configurations for the Same Identity Authentication Tenant [page 1969]

1.7.1.10.3 Configure Different Trust Configurations for the Same Identity Authentication Tenant

Tenant administrator can configure the issuer name in the request sent to the corporate identity providers when Identity Authentication acts as a proxy identity provider.

Context

> **Note**
>
> To configure Identity Authentication to use a different issuer name when communicating with Microsoft Entra ID (formerly known as Microsoft Azure Active Directory or Azure AD), see (Optional) Configure

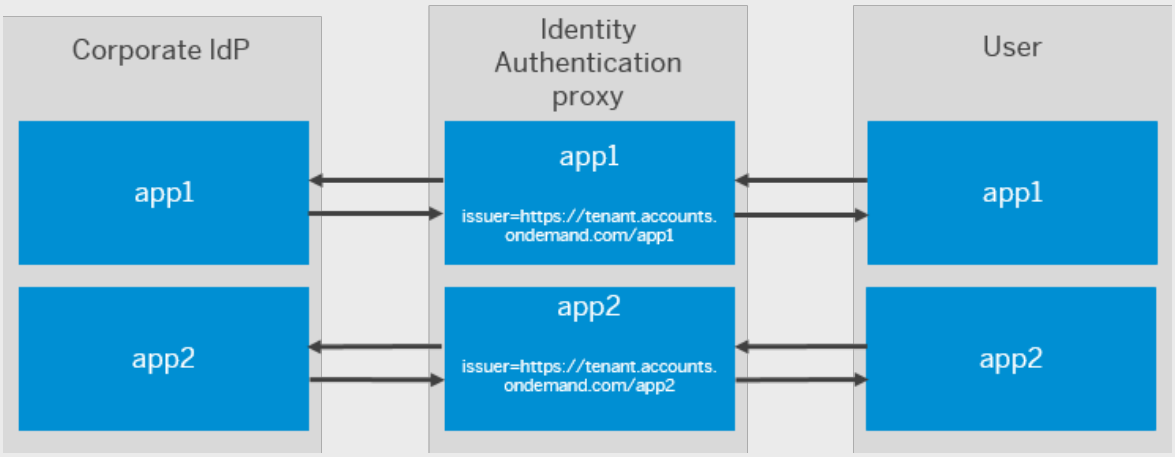
Different Trust Configurations for the Same Identity Authentication Tenant (Microsoft Entra ID Apps) [page 2956].

When Identity Authentication acts as a proxy identity provider you can have different trust configurations for the different applications at the corporate identity provider side. To do this you should configure Identity Authentication to use a different issuer name when communicating with the corporate identity provider, depending on the application for which the authentication is done.

When Identity Authentication issues a SAML2.0 authentication request, logout request or response to the corporate identity provider, then it uses the configured issuer name for the corresponding application.

When Identity Authentication verifies the SAML2.0 message coming from the corporate identity provider, then the verification is done against the configured issuer for the corresponding application.

Example



Identity Authentication acts as identity provider proxy and there are two configured applications app1 and app2. App1 is configured with `issuer=https://tenant.accounts.ondemand.com/app1`. App2 is configured with `issuer=https://tenant.accounts.ondemand.com/app2`. Both applications use one and the same corporate identity provider for authentication.

When App1 issues an authentication request to Identity Authentication, then Identity Authentication sends authentication request to the corporate identity provider, using `issuer=https://tenant.accounts.ondemand.com/app1`. The corporate identity provider authenticates the user and sends authentication response with `audience=https://tenant.accounts.ondemand.com/app1`. Then Identity Authentication sends authentication response to app1.

After that, the same user tries to authenticate to app2 from the same browser session. App2 issues an authentication request to Identity Authentication. Then Identity Authentication again sends authentication request to the corporate identity provider, but this time with `issuer=https://tenant.accounts.ondemand.com/app2`. Thus, the corporate identity provider can apply the specific authentication mechanisms, configured for `issuer=https://tenant.accounts.ondemand.com/app2`. After the authentication, the corporate identity provider issues an authentication response with `audience=https://tenant.accounts.ondemand.com/app2`. Then Identity Authentication sends authentication response to app2.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Choose *Conditional Authentication* > *Configure Requests to Corporate Identity Providers* > *SAML 2.0*.
6. Under *Configure Issuer Name*, type the issuer suffix, which you want to add to the Identity Authentication default issuer name.

   > **Note**
   >
   > The issuer name can contain Latin letters (A-Z and a-z), numbers, and the dash (-) character. It can be up to 36 characters.

   The issuer name, which will be used when sending SAML2.0 requests to the corporate identity provider appears under the input field. It is in the format `<Identity_Authentication_default_issuer_name>/<issuer_name_suffix_typed_in_the_input_field>`. For example, `https://my-tenant.accounts.ondemand.com/suffix/`.
7. Save your changes.

1.7.1.11 User Attributes

Tenant administrator has an overview of all the attributes provided to the application, regardless of the source of the values, and can provide the attributes needed by the application, specifying the attribute names expected by the application.

Context

> ⚠ Restriction
>
> The attributes configurations in the administration console for SAP Cloud Identity Services are relevant only when the application uses for authentication Identity Authentication, or when it uses a corporate identity provider (IdP), and the *Identity Federation* option is enabled.
>
> When the application uses a corporate IdP for authentication, and *Identity Federation* is disabled, Identity Authentication sends to the application the attributes that come from the corporate identity provider without changing them, and if configured, some of the same values with additional attribute names, namely configured on the trust to the corporate IdP, enriched assertion attributes or enriched token claims.

> → Tip
>
> For OpenID Connect, the supported scopes are `email`, `profile`, `openid`, and `groups`. The usage of these claims ensure uniqueness, especially in proxy mode, they are recommended over the configuration of attributes in the administration console for SAP Cloud Identity Services.

The application can get different values for a certain attribute name. The following options for sources are possible:

- *Identity Directory* - The local user attribute. You choose the value from a drop-down. See Configuring User Attributes from the Identity Directory [page 1973].
- *Corporate IdP* - The user attribute provided by the corporate IdP. You just enter the attribute name provided by the corporate IdP. See Configuring User Attributes from a Corporate Identity Provider [page 1978].
- *Expression* - A static or dynamic value. It can be a user attribute coming from *Identity Directory* or *Corporate Identity Provider*, or even a combination of all sources. See Configuring Attributes Based on Flexible Expressions [page 1979].

> → Tip
>
> The *Identity Directory* source maps to the *Assertion Attributes* term used before in this documentation.
>
> Depending on the scenario, the *Corporate Identity Provider* and *Expression* map to the *Default Attributes* term used before in this documentation.

> ⓘ Note
>
> You can specify multiple user attribute values for each user attribute. Up to 300 attribute values are allowed for self-created customer applications and automatically created single-tenant applications, and up to 50 attribute values for automatically created single-tenant applications.

- For OpenID Connect, the attributes are included in the token as string if there is one value, and array if multiple.
- For SAML 2.0, the attributes are included in the assertion as one attribute statement with multiple values in it.

SAP Cloud Identity Services supports nested attributes. You can use up to five layers of nesting. For example, `"kubernetes.io".serviceaccount.name`.

> ⚠ Restriction
>
> Attribute names that use the prefix `sap_` are reserved.

Self-Defined Attributes

If you have self-created applications or automatically created single-tenant applications in your SAP Cloud Identity Services tenant, you configure the attribute mappings under the *Self-Defined Attributes* section in the administration console. You must know the attributes that the application support, and configure the mappings accordingly.

Application Attributes

If you have subscribed multi-tenant applications in your SAP Cloud Identity Services tenant, the attributes supported by these applications are predefined and listed under the *Primary Attribute* section, with default mappings for source *Identity Directory*. You can see which attributes are supported, and add or remove mappings for the other sources - *Corporate Identity Provider* and *Expression*.

> → Tip
>
> For some subscribed applications, you might need to add custom attribute mappings (under the *Self-Defined Attributes* section). For example, an SAP BTP application connects to another application using a destination that is customer-managed. As *User ID* for principal propagation, the customer decides to use an attribute that is not in the list of predefined application attributes. So, this customer need to add the attribute configured in the destination as a self-defined attribute in the application in the SAP Cloud Identity Services tenant.

1.7.1.11.1 Configuring User Attributes from the Identity Directory

Specify how the local user attributes, configured to be collected by the registration and upgrade forms, are sent to the application.

Context

Identity Authentication defines default names for the user attributes, but you can change them in accordance with your requirements.

You configure the attributes by defining which user attribute corresponds to the user attribute that you set for the registration and upgrade forms. You can also specify multiple user attributes for each user attribute. You perform this mapping to help the application use the same user attribute for different scenarios that require several user attributes.

> **Note**
>
> The user attribute name must match the name that the application is expecting.

The attributes are also put in the `id_token` if the application is OpenID connect. For more information, see Configuring OpenID Connect (OIDC) [page 2636].

By default, Identity Authentication sets only the following user attribute names which are added at the creation of the application:

User Attribute	User Attribute Name
First Name	first_name
Last Name	last_name
Language	locale **Note** `locale` takes as value the language of the user. You can view the configured user language in the administration console for SAP Cloud Identity Services. For more information, see Configuring User Attributes from the Identity Directory [page 1973].
Email	mail
Global User ID	user_uuid

> **Note**
>
> The **Value** column lists the attributes that can be shown on the registration and upgrade forms. The **Name** lists the attributes that are sent in the assertion.

Identity Authentication supports also the following user attributes:

- `Application Activation Time`
- `Application Custom Attribute 1`
- `Application Custom Attribute 2`
- `Application Custom Attribute 3`
- `Application Custom Attribute 4`
- `Application Custom Attribute 5`

> ### Note
>
> The application custom attributes are configured by the application (service provider). They can't be defined for the user.
>
> Custom attributes must not be used to store sensitive personal data.

- `City`
- `Company`
- `Company City`
- `Company Country/Region`
- `Company State/Province`
- `Company Street Address`
- `Company Street Address 2`
- `Company ZIP/Postal Code`
- `Contact by Email`
- `Contact by Telephone`
- `Corporate Groups`

  > ### Note
  >
  > This attribute is applicable for the corporate user store scenarios and contains the groups the user in the corporate user store is assigned to.

- `Cost Center`
- `Country/Region`
- `Department`
- `Display Name`
- `Email Verified`
- `Employee Number`
- `All Groups`

  > ### Note
  >
  > Lists all user groups, all application-specific groups of type `userGroup`, independent of the application name, and all application-specific groups of type `authorization`, belonging to the current application only, that a user is a member of.
  >
  > Use `Groups` as user attribute name for application on the SAP BTP, Cloud Foundry Environment.

- `Application Groups`

  > ### Note
  >
  > Lists only the application-specific groups of type `userGroup`, belonging to the current application only, to which the user is assigned to.

- `Application Groups - external name`
  Unique within the application.

> ⓘ Note
>
> Lists only the application-specific groups of type `userGroup`, belonging to the current application only, to which the user is assigned to.

- `License Groups`

> ⓘ Note
>
> The license group is a special package license group in `Cloud Identity Services` of type `License` for AI features across the SAP portfolio. Only the users that are assigned to these license groups can access the premium Joule scenarios.

> → Remember
>
> The name must be `sap_licenses`.

- `Company Industry`
- `Job Function`
- `Login Name`
- `Middle Name`
- `Company Relationship`
- `State/Province`
- `Street Address`
- `Street Address 2`
- `Telephone Number`
- `Salutation`
- `User ID`
- `ZIP/Postal Code`.

> → Remember
>
> The application custom attributes are configured by the application (service provider). They can't be defined for the user.
>
> Custom attributes must not be used to store sensitive personal data.

> ⓘ Note
>
> The **Value** column lists the attributes that can be shown on the registration and upgrade forms. The **Name** lists the attributes that are sent in the assertion.
>
> The configured custom attributes are also put in the `id_token` if the application is OpenID connect. For more information, see Configuring OpenID Connect (OIDC) [page 2636].

> → Remember
>
> When the application uses a corporate IdP for authentication, and *Identity Federation* is disabled, the user attributes configurations in the administration console for SAP Cloud Identity Services aren't relevant. In such scenarios Identity Authentication sends to the application the user attributes that come from the corporate identity provider without changing them. For more information about the corporate identity

provider scenario, see Corporate Identity Providers [page 2556] and Configure Identity Federation [page 2614].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Attributes*.
6. Under the *Self-defined Attributes* section, choose *Expand All* to view all the information about the user attributes.
7. **Optional:** Choose the *Add* button:
   a. Provide a name for the attribute.
   b. Choose *Identity Directory* source.
   c. Choose a value from the drop-down list.
8. **Optional:** Choose the plus button next to the attribute to set a new value for the attribute.
9. Save your configuration.

Related Information

Configure Registration and Upgrade Forms [page 2046]
Create a New Application [page 1922]

1.7.1.11.2 Configuring User Attributes from a Corporate Identity Provider

You can configure the value of existing application-defined attributes, like email, first name, last name, for example to values coming from the corporate identity provider (IdP), and add new attributes.

Context

Configure the user attributes as they come from the corporate identity provider (IdP).

> ⓘ Note
>
> For corporate IdPs configured for OpenID Connect (OIDC) , only attributes coming from ID tokens are relevant.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Attributes*.
6. Depending on the type of your application go to:
   - *Application Attributes* - for subscribed multitenant applications.
     1. Choose the plus button next to an attribute to set multiple values for the attribute.
     2. Choose *Corporate Identity Provider* source.
     3. Provide the new value.

     > → Tip
     >
     > You can enable or disable the attribute mappings inherited from the subscribed multitenant applications:
     >
     > - To disable the attribute mappings, choose the ⊗ *disable* button on the right of the inherited attribute.

- To enable the attribute, choose ✓ *enable* button on the right of the inherited attribute.

- *Self-defined Attributes* - for self-created applications or automatically created single-tenant applications.
  1. Choose *Add button to add new attribute for the application* > *provide the name* > *Corporate Identity Provider* > *provide the value* .
  2. Choose *plus button next to an attribute to set multiple values for the attribute* > *Corporate Identity Provider* > *provide the new value* > .

7. Save your configuration.

1.7.1.11.3 Configuring Attributes Based on Flexible Expressions

You can configure attributes based on flexible expressions for the application.

Context

The system sends attributes from Identity Authentication to the application in the assertion. You can set static attributes like `location` and `company` with values *Europe* and *Company A*. The application then displays Europe and Company A on its main page.

The attributes are also put in the ID and access tokens if the application is OpenID Connect. For more information, see Configuring OpenID Connect (OIDC) [page 2636].

For both the SAML 2.0 and OpenID Connect applications, you can configure attributes with dynamic values to be added into the assertions in the following pattern: `<prefix> ${attribute_technical_name>} <suffix>`

> ⚠ Restriction
>
> For OpenID Connect applications, you can't set standard claims or SAP-specific claims (prefixed with `sap_`) via the configuration of attributes with default values. For a list of claims supported by SAP Cloud Identity Services, see Claims of SAP Cloud Identity Services OAuth Tokens [page 2744].

Supported Attributes

Supported Attributes

Attribute Display Name	Attribute Technical Name
Salutation	title
First Name	firstName
Middle Name	middleName
Last Name	lastName

Attribute Display Name	Attribute Technical Name
Email	mail
Telephone Number	telephone
Language	language
Logon Name	loginName
Display Name	displayName
User ID	uid
User UUID	userUuid
User Type	type
Street Address	street
Street Address 2	street2
City	city
ZIP/Postal Code	zip
Country	country
State/Province	state
Cost Center	costCenter
Department	department
Division	division
Employee Number	personnelNumber
Company	company
Company Street Address	companyStreet
Company Street Address 2	companyStreet2
Company City	companyCity
Company ZIP/Postal Code	companyZip
Company Country	companyCountry
Company State/Province	companyRegion
Company Industry	industry
Job Function	jobFunction
All Groups	companyGroups → Tip The attributes `companyGroups` and `corporateGroups` support regular expressions, so that they can be filtered.
Application Groups	applicationGroups

Attribute Display Name	Attribute Technical Name
Corporate Groups **Note** This attribute is applicable for the corporate user store scenarios and contains the groups the user in the corporate user store is assigned to. **→ Tip** The `companyGroups` and `corporateGroups` attributes support regular expressions. You can use an expression to filter these attributes. Both the regex filter and the value sent to the application are based on the group's `Name` field. Other group fields, such as `Display Name`, are not considered.	corporateGroups
Contact by Email	contactPreferenceEmail
Contact by Telephone	contactPreferenceTelephone
Application Activation Time	activationTime
Custom Attribute 1	customAttribute1
Custom Attribute 2	customAttribute2
Custom Attribute 3	customAttribute3
Custom Attribute 4	customAttribute4
Custom Attribute 5	customAttribute5
Custom Attribute 6	customAttribute6
Custom Attribute 7	customAttribute7
Custom Attribute 8	customAttribute8
Custom Attribute 9	customAttribute9
Custom Attribute 10	customAttribute10

Examples for attributes with dynamic values:

If you set `${uid}` as a value, the response returns the ID of the user to the application:

Example

```
SAML 2.0
<Attribute Name="User ID">
       <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                               xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"
                               xsi:type="xs:string"
                               >P123456</AttributeValue>
</Attribute>
OpenID Connect
 "User ID": "P123456"
```

If you set `${customAttribute1}` as a value, the response returns the first custom attribute of the user to the application, if there is one. If the user doesn't have a custom attribute, the response contains an empty attribute:

Example

```
SAML 2.0
<Attribute Name="Custom Attribute">
       <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                       xsi:type="xs:string"
                       >{customAttribute1}
</AttributeValue>
OpenID Connect
 "Custom Attribute": "{customAttribute1}"
```

If you set `${companyGroups:regex[Admin]}` as a value, the response returns the groups, whose `Name` field contains "Admin". The regex filter applies to the group's `Name` field only. Other fields such as `Display Name` aren't considered. The `Name` field value is also the value sent to the application for each matching group:

Example

```
SAML 2.0
<Attribute Name="Groups">
       <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                       xsi:type="xs:string"
                       >Admins</AttributeValue>
       <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                       xsi:type="xs:string"
                       >Administrators</AttributeValue>
OpenID Connect
 "Groups": [
    "Admins"
    "Administrators",
 ]
```

Merge User Attributes

For both the SAML 2.0 and OpenID Connect applications, you can define attributes with the same name, but with different values. You can also define a user attribute and an attribute with a default value with the same name. The response then merges these attributes into a multivalue attribute. As a result, several values may appear for a single-value attribute based on the configuration.

The order of the attribute's values in the assertion is arbitrary.

For example, you've defined the `mail` user attribute and at the same time the `mail` attribute with default value `example@example.com`.

Example

When the user Dona Moore logs on, the response returns `mail` as a multivalue attribute with the two values.

```
SAML 2.0
 <Attribute Name="mail">
               <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                               xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"
                               xsi:type="xs:string"
                               >example@example.com</AttributeValue>
               <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
```

```
                                    xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"
                                    xsi:type="xs:string"
                                    >dona.moore@example.com</AttributeValue>
</Attribute>
OpenID Connect
  "mail": [
    "dona.moore@example.com",
    "example@example.com"
  ]
```

Concatenate User Attributes

For both the SAML 2.0 and OpenID Connect applications, you can define attributes by concatenating up to five single-value attributes to create a combined attribute for your application. You can concatenate the attributes in the following pattern: `<prefix> ${<attribute_technical_name1>} <infix>${<attribute_technical_name5>}<suffix>`

⚠ Restriction

You can't concatenate:

- single-value with multi-value attributes
- multi-value with other multi-value attributes
- the attributes: `companyGroups`, `applicationGroups`, `corporateGroups`
- more than five attributes

Example

You want to define a custom work email for the employees at Company A from their first name, corporate number, and the company's domain. You have the following attributes for the user Dona Moore:

Attribute	Value
firstName	Dona
urn:sap:Corporate.numbervalue	123456
customAttribute1	example.com

You set `${firstName:function[lowercase]}_ ${urn:sap:Corporate.numbervalue}@${customAttribute1}` as value, and when Dona Moore logs on, the response returns `custom-mail` as a concatenated attribute.

```
SAML 2.0
<Attribute Name="custom-mail">
                                    <AttributeValue xmlns:xs="http://www.w3.org/
2001/XMLSchema"
                                    xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance"xsi:type="xs:string"
                                    >dona_123456@example.com</AttributeValue>
</Attribute>
OpenID Connect
  "custom-mail": "dona_123456@example.com"
```

Identity Federation

- *Identity Federation* not configured
  When the application uses corporate IdP for authentication, and the *Use Identity Authentication user store* option under *Identity Federation* is disabled, the attributes configurations with default values in the administration console for SAP Cloud Identity Services aren't relevant. For more information about the corporate identity provider scenario, see Corporate Identity Providers [page 2556] and Configure Identity Federation [page 2614].
  The configuration of the attributes with default values for the system applications is disabled.
- *Identity Federation* configured
  When the application uses a corporate IdP for authentication, and the *Use Identity Authentication user store* under *Identity Federation* option is enabled, the attributes with default values in the administration console for SAP Cloud Identity Services can be configured to reference attributes coming from the assertion of the corporate IdP for the user and merge them with the attributes coming from Identity Authentication, and thus be sent to the application.
  To configure Identity Authentication to reference attributes coming from the assertion of the corporate IdP, you must use the following format for the attribute:
  `<attribute_name> = <prefix> ${corporateIdP.<corporateIdP_attribute_name><:regex[filter]><:function[<method>]>} <suffix>`

Parameter	Required	Notes
`attribute_name`	Yes	The name of the attribute as defined in the administration console. Free text.
`prefix`	No	Free text.
`corporateIdP`	Yes	Fixed string, indicating that the value is taken from the assertion coming from the corporate IdP.
`corporateIdP_attribute_name`	Yes	The specific attribute from the corporate IdP, whose value is taken.
`:regex[<filter>]`	No	Filter the attributes from the corporate IdP.
`:function[<method>]`	No	Methods to convert the attributes. Currently the supported methods are: • uppercase - the attribute is converted to uppercase letters. • lowercase - the attribute is converted to lowercase letters.
`suffix`	No	Free text.

> **Example**
>
> For example, you have set up a scenario where Identity Authentication acts as a proxy. The default authenticating identity provider is the corporate IdP, and the *Identity Federation* option is configured for that corporate IdP.

The corporate IdP is configured to send the groups with the `group` user attribute.

You want to send the groups coming from the corporate IdP to the application so you have defined the following attribute in the administration console for SAP Cloud Identity Services:

Configuration of Attributes with Default Values in Administration Console

Attribute	Value
groups	Group ${corporateIdP.groups} Member

Dona Moore is assigned to the groups *Management* and *Development* in the corporate IdP. When she logs on to the corporate portal of the company, Identity Authentication sends the `groups` coming from the corporate IdP in the following way:

```
SAML 2.0
<Attribute Name="groups">
                <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                                xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
                                xsi:type="xs:string"
                                >Group Development Member</AttributeValue>
                <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                                xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
                                xsi:type="xs:string"
                                >Group Management Member</AttributeValue>
</Attribute>
OpenID Connect
  "groups": [
    "Group Development Member",
    "Group Management Member"
  ]
```

The example can be expanded with the filtering option.

Example

Again, you have a scenario where Identity Authentication is a proxy. The default authenticating identity provider is the corporate IdP, and the *Identity Federation* option is configured for that corporate IdP.

The corporate IdP is configured to send the groups with the `group` user attribute.

You don't want to send all the groups coming from the corporate IdP to the application. One reason for not sending all groups is the 16k size limit on OIDC access tokens. So, you have defined the following attribute in the administration console for SAP Cloud Identity Services:

Configuration of Attributes with Default Values in Administration Console

Attribute	Value
groups	${corporateIdP.groups:regex[ABC-]}

Michael Adams is assigned to the groups *ABC-Management*, *Development* , and *ABC-Everyone* in the corporate IdP. When he logs on to the corporate portal of the company, Identity Authentication sends just those `groups` coming from the corporate IdP that matches *ABC-*, in the following way:

```
SAML 2.0
```

```
</Attribute>
                <Attribute Name="groups"> <AttributeValue xmlns:xs="http://
www.w3.org/2001/XMLSchema"
                                  xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
                                  xsi:type="xs:string"
                                  >ABC-Everyone</AttributeValue>
<AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
                                  xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
                                  xsi:type="xs:string"
                                  >ABC-Management</AttributeValue> </
Attribute>
OpenID Connect
  "groups": [
    "ABC-Everyone",
    "ABC-Management"
  ]
```

Example

Another scenario is where Identity Authentication is again a proxy. The default authenticating identity provider is the corporate IdP, and the *Identity Federation* option is configured for that corporate IdP.

The corporate IdP is configured to send the email with the `mail` user attribute. The incoming mail attribute from corporate IdP is in mixed case and it is converted to lower case. For example, Michael Adams' email in the corporate IdP is in mixed case Michael.Adams@example.com, and it is converted into lower case michael.adams@example.com.

Configuration of Attributes with Default Values in Administration Console

Attribute	Value
mail	${corporateIdP.mail:function[lowercase]}

→ Remember

When Identity Authentication is configured to reference an attribute from the corporate IdP, but this attribute isn't sent in the corporate IdP assertion, the attribute isn't sent to the application either.

If the definition of the attribute includes prefix and/or suffix, only the prefix and/or suffix is sent.

However, if the corporate IdP is not configured to send the **phone** attribute, the response includes only the prefix and suffix, defined in the administration console for SAP Cloud Identity Services:

Example

For example, you want to send the **phone** attribute coming from the corporate IdP to the application. You have defined the following attribute in the administration console for SAP Cloud Identity Services:

Configuration of Attributes with Default Values in Administration Console

Attribute	Value
Phone	+49 ${corporateIdP.phone} Corporate Phone

```
SAML 2.0
</Attribute>
                  <Attribute Name="Phone"> <AttributeValue
xmlns:xs="http://www.w3.org/2001/XMLSchema"
                                  xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance"
                                  xsi:type="xs:string"
                                  >+49 123 456789 Corporate Phone</
AttributeValue>
</Attribute>
OpenID Connect
"Phone": "+49 123 456789 Corporate Phone"
```

Send Identity Directory Custom Schema Attributes

You can configure Identity Authentication to send the Identity Directory custom schema attributes as attributes into authentication tokens to applications.

You can define complex custom schema attributes with single-value child attributes.

Example

For example, you have set up a scenario where Identity Authentication acts as a proxy. The default authenticating identity provider is the corporate IdP, and the *Identity Federation* option is configured for that corporate IdP.

Michael Adams is a user from the corporate identity provider. He is created on the proxy IdP with the custom schema `urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile` with two single-valued attributes, `birthday` and `hobby`, and the complex attribute `name` with its child attribute `firstName`. He logs on to the company's portal with the corporate identity provider.

The default attributes for the application are configured in the administration console as follows:

Configuration of Attributes with Default Values in Administration Console

Attribute	Value
name	${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.name.firstName}
hobby	${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.hobby}
birthday	${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.birthday}

When Michael logs on the application, the values "Michael", "cycling", and "2000-01-02T0:00:00Z" are added to application token during authentication, and received by the application.

The attributes are added both to SAML 2.0 and OIDC tokens.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Single Sign-On*, choose *Attributes*.
6. Depending on the type of your application go to:
   - *Application Attributes* - for subscribed multitenant applications.
     1. Choose the plus button next to an attribute to set multiple values for the attribute.
     2. Choose *Corporate Identity Provider* source.
     3. Provide the new value.

     > **→ Tip**
     >
     > To restrict the value of an application attribute:
     >
     > 1. Deactivate the existing attribute.
     > 2. Add a new value with a flexible expression.

   - *Self-defined Attributes* - self-created applications or automatically created single-tenant applications.
     1. Choose *Add button to add new attribute for the application* > *provide the name* > *Expression* > *provide the value*.
     2. Choose *plus button next to an attribute to set multiple values for the attribute* > *Expression* > *provide the new value*.
7. Save your configuration.

1.7.1.12 Configure the Subject Name Identifier Sent to the Application

The `Subject Name Identifier` is a profile attribute that Identity Authentication sends to the application as `name ID` in the SAML 2.0 assertions, and as `subject` in the OpenID Connect tokens. The application then uses this attribute to identify the user.

Context

You can choose primary and fallback attributes to uniquely identify the user during logon.

The *Primary Attribute* value can be chosen from three sources:

- *Identity Directory* - This is the local user attribute. You choose the value from a drop-down.
  The user is identified in one of the following ways:
  - Global User ID
  - User ID
  - Email
  - Display Name
  - Login Name
  - Employee Number.

  > ### Note
  >
  > `Global User ID`, `User ID`, `Login Name` and `Email` can be unique for the tenant. This depends on the tenant configurations.
  >
  > The configuration of the `Subject Name Identifier` attribute for the system applications is disabled. The default setting for these applications is `User ID`.

  > ### Caution
  >
  > Identity Authentication does not check the `Employee Number` attribute for uniqueness. Be sure that the users receive unique employee numbers.

- *Corporate Identity Provider* - The user attribute provided by the corporate identity provider (IdP). You just enter the attribute name provided by the corporate IdP.
- *Expression* - A static or dynamic value. It can be a user attribute coming from:
  - Identity Directory
  - Corporate Identity Provider
  - a combination of the Identity Directory and Corporate Identity Provider
  - a custom single-value attribute defined in a custom schema.

  > ### Caution
  >
  > Attributes of type complex and multi-value attributes are not supported when the source is a custom schema.

  The user is identified by setting an attribute with dynamic value in the following pattern: `<prefix> ${attribute_technical_name} <suffix>`.

  > ### Note
  >
  > If the attribute comes from a custom schema, the pattern is: `<prefix> ${SchemaID.attribute_technical_name} <suffix>` . Attributes of type complex and multi-value attributes are not supported when the source is a custom schema.

  Expand the **Supported Attributes** table below to see the technical names of the attributes that can take dynamic values:

  Supported Attributes

Attribute	Attribute Technical Name
Email	mail

Attribute	Attribute Technical Name
Telephone Number	telephone
Logon Name	loginName
Display Name	displayName
User ID	uid
Global User ID	userUuid
Employee Number	personnelNumber
Custom Attribute 1	customAttribute1
Custom Attribute 2	customAttribute2
Custom Attribute 3	customAttribute3
Custom Attribute 4	customAttribute4
Custom Attribute 5	customAttribute5
Custom Attribute 6	customAttribute6
Custom Attribute 7	customAttribute7
Custom Attribute 8	customAttribute8
Custom Attribute 9	customAttribute9
Custom Attribute 10	customAttribute10
SP (service provider) user nameID	name_id
SP (service provider) user Custom Attribute 1	spCustomAttribute1
SP (service provider) user Custom Attribute 2	spCustomAttribute2
SP (service provider) user Custom Attribute 3	spCustomAttribute3
SP (service provider) user Custom Attribute 4	spCustomAttribute4
SP (service provider) user Custom Attribute 5	spCustomAttribute5
NameID coming from the assertion of the corporate IdP	corporateIdP.NameID
Attribute coming from the assertion of the corporate IdP	corporateIdP.<corporateIDP attribute>

→ Remember

If the *Corporate Identity Provider* or *Expression* configuration options are used, *Use Identity Authentication user store* must be enabled. When the application uses corporate IdP for authentication, and *Use Identity Authentication user store* is disabled, the `Subject Name Identifier` attribute configurations in the administration console for SAP Cloud Identity Services are not relevant. In such scenarios Identity Authentication sends to the application the `Subject Name Identifier` attribute that comes from the corporate identity provider without changing it. For more information about the corporate identity provider scenario, see Corporate Identity Providers [page 2556] and Configure Identity Federation [page 2614].

Apart from the primary attribute configuration you can also configure a fallback subject name identifier. The fallback subject name identifier is used only when the primary identifier is not available. If the primary identifier is not available, and you haven't set a fallback attribute, the authentication of the user fails.

Optionally, you can configure the default name identifier format of the name ID attribute for SAML 2.0 applications.

> ⚠ Caution
>
> When configuring the `Subject Name Identifier`, take into consideration that some of the attributes can be modified by the users.

> ⓘ Note
>
> When a subscribed application becomes a child application, the configuration of the `Subject Name Identifier` of that child application can be different from the parent application or from the application it is subscribed to. You can make the configuration of the `Subject Name Identifier` the same as the parent application by choosing the *Inherit from Parent* button on the top right-hand corner of the screen. You can also make the configuration of the `Subject Name Identifier` the same as the application it is subscribed to by choosing the *Inherit from Source* button on the top right-hand corner of the screen. Depending on your configuration, either the *Inherit from Parent* or the *Inherit from Source* button is active, or both buttons are active.

To set the `Subject Name Identifier` attribute, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Subject Name Identifier*.
6. Select one of the following:

   - Identity Directory:
     - Select an attribute from the drop down: `Global User ID`, `User ID` (this is the default setting), `Email`, `Display Name`, `Login Name`, `Employee Number`.

       > ⓘ Note
       >
       > If you select *Login Name*, or *Employee Number*, and the selected attribute has no value set for the user, the user is not able to log on the application. The message "**HTTP Status 401 – Unauthorized**" is displayed when the user provides credentials and logs on. In this case, configure also the fallback attribute.

- (optional) Select a fallback attribute from the drop down: `None` (this is the default setting), `Global User ID`, `User ID`, `Email`, `Display Name`, `Login Name`, `Employee Number`.

- Corporate Identity Provider
  - Enter the attribute name provided by the corporate IdP.

    > → Tip
    >
    > When Identity Authentication acts as proxy IdP, and the users have no profiles in Identity Authentication, you can set an attribute with the value coming from the corporate IdP, or use the *Expression* configuration option.

  - (optional) Select a fallback attribute from the drop down: `None` (this is the default setting), `Global User ID`, `User ID`, `Email`, `Display Name`, `Login Name`, `Employee Number`.

- Expression:
  - Enter a static or dynamic value. It can be a user attribute coming from Identity Directory, or Corporate Identity Provider, or even a combination of all sources. To set an attribute with dynamic value use the following pattern `<prefix> ${attribute_technical_name} <suffix>`. For example: `Phone ${telephone}`

    > ⓘ Note
    >
    > If Identity Authentication acts as proxy IdP, and the users have no profiles in Identity Authentication, set an attribute with the following dynamic value: <prefix> ${corporateIdP.<corporateIDP attribute>} <suffix>

  - (optional) Select a fallback attribute from the drop down: `None` (this is the default setting), `Global User ID`, `User ID`, `Email`, `Display Name`, `Login Name`, `Employee Number`.

7. Save your selection.

   Once the application has been changed, the system displays the message `Application <name of application> updated`.

(Optional) Configure the Default Name ID Format Sent to the Application

The tenant administrator can set a default name ID format via the administration console for SAP Cloud Identity Services.

Context

The name ID format is used in the `Format` attribute of the `NameID` element that Identity Authentication sends to the application with the SAML assertion. This is the default name ID format. It is used only in case the application or the service provider does not request another name ID format with the SAML authentication request.

Identity Authentication supports the following name ID formats:

Name ID Format	URI	Description
Unspecified	urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified	Identity Authentication does not use a specific format to express the identity of the user. The application receives the value of the user attribute that is selected as name ID attribute. By default this is the default Name ID format.
Email address	urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress	The format of the name ID is an email address. You can configure this setting when you have chosen as name ID attribute a user attribute that contains email. **Note** Identity Authentication does not check if the content of the name ID attribute is email address. You can decide which name ID attribute to configure for the application. Make sure that it contains email address in case you want to conform to the SAML2 specification.

Note

The configuration of the default name ID format for the system applications is disabled. The default setting for these applications is `Unspecified`.

→ Remember

When the application uses corporate IdP for authentication, and *Use Identity Authentication user store* is disabled, the default name ID attribute configurations in the administration console for SAP Cloud Identity Services are not relevant. In such scenarios Identity Authentication sends to the application name ID format that comes from the SAML assertion sent from the corporate IdP without changing it. For more information about the corporate identity provider scenario, see Corporate Identity Providers [page 2556] and Configure Identity Federation [page 2614].

To set the default name ID format, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Default Name ID Format*.
6. Select the default name ID format from the following:
   - Unspecified
   - Email
7. Save your selection.

   Once the application has been changed, the system displays the message `Application <name of application> updated`.

Related Information

Create a New Application [page 1922]
Configure Trust [page 1941]

1.7.1.13 Convert Subject Name Identifier to Uppercase or Lowercase

Tenant administrator can apply function to change the subject name identifier to uppercase or lowercase letters depending on the need of the application.

Context

The setting is applied in all cases when Identity Authentication issues an assertion or id token - logon in Identity Authentication or delegated authentication to corporate identity provider with or without enabled identity federation.

> **Note**
>
> Conversion for subject name identifier in locale "tr", "az" or "lt" is not supported. If subject name identifier is in "tr", "az" or "lt" locale the conversion may not work properly.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Under the *Trust* tab, choose *Apply Function to Subject Name Identifier*.
5. Choose one of the options:
   - None - default configuration
   - Uppercase - the subject name identifier is converted to uppercase letters.
   - Lowercase - the subject name identifier is converted to lowercase letters.
6. Save your configuration.

1.7.1.14 Authentication

To learn about	See
How to define rules for authentication in accordance with the risk	Configure Risk-Based Authentication for an Application [page 2007]
Enable social sign-on authentication for an application	Enable or Disable Social Sign-On for an Application [page 2020] **Note** The content in this section is not relevant for China (Shanghai) region.
How to allow users to log on to an application from the corporate network without entering their username and password	Enable or Disable Kerberos Authentication for an Application [page 2556]
How to configure the type of authentication when API methods of Identity Authentication are used	API Authentication [page 1996]

1.7.1.14.1 API Authentication

Developers can choose the type of authentication when API methods of Identity Authentication are used.

The certificate to be used for authentication by the REST APIs of Identity Authentication must be requested from the SAP Support Portal.

Configure Secrets for API Authentication [page 1997]
: This document describes how developers configure secrets with scopes and validity for client authentication.

Unlock Client ID [page 1999]
: Unlock the client ID after five failed logon attempts before the automatic unlock time of 60 minutes has passed.

Disable Client ID Locking [page 2000]
: You can disable the automatic lock of the client ID after five failed logon attempts.

Configure Certificates for API Authentication [page 2001]
: This document describes how developers configure the certificates used for authentication when the API methods and OpenID Connect scenarios of Identity Authentication are used.

Configure JWT for OAuth Client Authentication [page 2003]
: Configure the JSON Web Token (JWT) - the issuer and subject of tokens for JWT client authentication in token requests, or the URI for JSON web key retrieval for client authentication.

SCIM REST API (Deprecated) Authentication Mechanisms [page 2006]
: See how to configure the authentication mechanisms for the Identity Authentication API (Deprecated) [page 2796] methods of Identity Authentication.

1.7.1.14.1.1 Configure Secrets for API Authentication

This document describes how developers configure secrets with scopes and validity for client authentication.

Context

You can use a client ID and a secret to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Password REST API) to the tenant of Identity Authentication are used. The client ID and secret can also be used in the OpenID Connect scenarios of Identity Authentication.

The client ID is in the universally unique identifier (UUID) format. For example, `1ab7c243-5de5-4530-8d14-1234a26373ab`.

> → Remember
>
> The User ID and a password (secret) to authenticate the client (relying party) in the OpenID Connect scenario must be encoded using the "application/x-www-form-urlencoded" encoding algorithm.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.

   You can see the *Client ID* generated for the chosen application.
6. Choose the *Add* button in the *Secrets* section.

   > ⚠ Restriction
   >
   > You can generate up to 20 client secrets per application.
7. Provide the required info in the pop up.

Description	This field is optional.
Expire in	You can choose from three options: • 1 year • 2 years • Never
Scope	• Application - Secrets with *Application* scope are used to update the Application configurations. • Application Users - select this option to generate a secret to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Service REST API) are used. • OpenID - select this option to generate a secret to authenticate in the OpenID Connect scenario. **Note** By default all options are selected. Your secret can be used for all scopes.

8. Save your configuration.

   A pop up with the generated credentials appears. Make sure that you save the client secret for the client ID. You will need it for the API authentication, but you will not be able to retrieve it from the system later.

Results

Once your secret is generated you can see a table with your secrets and information about them.

1.7.1.14.1.2 Unlock Client ID

Unlock the client ID after five failed logon attempts before the automatic unlock time of 60 minutes has passed.

Context

The client ID locks for 60 minutes after five failed logon attempts. After 60 minutes the client ID is automatically unlocked.

To unlock the client ID before the automatic unlock time of 60 minutes has passed follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application with a locked client ID.
4. Under *API AUTHENTICATION*, choose *Client ID and Secrets*.
5. Choose *Unlock* next to *Client ID Status*.

> → Remember
>
> You can only unlock locked client IDs. If the client ID is not locked, the *Unlock* button is disabled.

Task overview: API Authentication [page 1996]

Disable Client ID Locking [page 2000]

1.7.1.14.1.3 Disable Client ID Locking

You can disable the automatic lock of the client ID after five failed logon attempts.

Context

By default the client ID locks for 60 minutes after five failed logon attempts.

You can disable the automatic lock of the client ID via the administration console for SAP Cloud Identity Services. Use this option to disable the automatic lock in cases when the client ID has a limited scope and the client ID secret(s) are automatically generated.

> ### Note
>
> When you disable the *Client ID Lock* option for a client ID that is already locked, this resets the failed logon attempts counter but the client ID remains locked. If you want to unlock the client ID before the automatic unlock time of 60 minutes has passed you must unlock it manually. For more information, see Unlock Client ID [page 1999].

"

To disable the *Client ID Lock* option, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.
4. Under *API AUTHENTICATION*, choose *Client ID and Secrets*.
5. Disable the *Client ID Lock*.

   If the operation is successful, you receive the following message: `Client ID locking updated.`. The slider next to *Client ID Lock* is switched to *OFF*.

   > ### Note
   >
   > If you want to enable client ID password locking for the application, drag the slider to *ON*.

1.7.1.14.1.4 Configure Certificates for API Authentication

This document describes how developers configure the certificates used for authentication when the API methods and OpenID Connect scenarios of Identity Authentication are used.

Prerequisites

SAP Support Portal Home (For trusted CA Scenario) - If you want to configure a certificate, using your own trusted CA report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`. Attach to the incident the root and intermediate certificates and provide the Identity Authentication tenant ID.

> **Note**
>
> `Tenant ID` is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the `tenant ID`. For more information about your tenants, see View Assigned Tenants and Admins.

Context

You can use a certificate to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Service REST API) to the tenant of Identity Authentication are used. The certificate can also be used in the OpenID Connect scenarios of Identity Authentication.

For the configuration, you have to provide the base64-encoded certificate as a file or plain text, or you can generate a certificate via the administration console. You can enter a maximum of 80 certificates.

By default all scope options are selected and the *Scope* field is disabled. Your certificates are used for all scopes.

Identity Authentication, by default, supports the following as trusted certificate authorities (CA): SAP Passport CA G2, SAP SSO CA G2, SAP Cloud Root CA, SAP Global Root CA, DigiCert TLS RSA SHA256 2020 CA1, DigiCert Global Root CA, SAP Cloud Platform Client CA, ConnectivityCA.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.
6. Choose the *Add* button in the *Certificates for API Authentication* section.
7. **Optional:** Provide description for the certificate.
8. Choose one of the following options:

Certificate Options	Notes
Generate Certificate	Fill in the fields under *Generate Certificate* and choose the *Generate* button. **Note** You must provide a Common Name (CN) and password to generate the certificate. Once the certificate is generated, it is saved as a *.p12* file. The system populates the *Insert as Text* field with it, and provides the certificate attributes in the Subject DN. The common name (CN) in the generated certificate is in the format `<common name>` (`<admin user ID>`), where common name is the CN provided by the administrator, and admin user ID is the administrator's user id. The maximum length of the combination of `<common name>` (`<admin user ID>`) is 64 characters. **→ Remember** You can generate up to 500 certificates per year. If you reach the limit, you can still upload your certificate, or insert it as a text.
Upload Certificate	You must use `.cer` or `.crt` files. **Note** Once the certificate is uploaded, the system populates the Insert as Text field with it
Insert Certificate	Insert the certificate in the text field.

> ⚠ Restriction
>
> You can't use one and the same certificate for application and system as administrator authentication.

9. Choose the *Add* button at the bottom of the page.

   Once the certificate has been configured, the system displays the message `Certificate for API authentication updated`.

> → Tip
>
> When the certificate expires, follow the procedure again and configure a new one.

Results

Once your certificate is added you can see a table with all your certificates and information about them.

Invitation REST API [page 2802]
User Management REST API [page 2805]

1.7.1.14.1.5 Configure JWT for OAuth Client Authentication

Configure the JSON Web Token (JWT) - the issuer and subject of tokens for JWT client authentication in token requests, or the URI for JSON web key retrieval for client authentication.

Prerequisites

You have an OpenID Connect application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.
6. Under *JSON Web Tokens*, configure one of the following options and save your changes:

   You can enter a maximum of 20 of each type of trust.

   - (For RFC 7523-based JWT client tokens) Choose the *Add* button for *Configure Trust by Issuer* and provide the required info in the popup:

     Configure Trust by Issuer

Field	Notes
Description	(Optional) - Provide information about the token in the provided field.
Choose *Issuer Configuration* > *Manual Configuration* > radio-button. **Note** When you choose *Manual Configuration* radio-button the *Corporate Identity Provider* section is not configurable.	Under *Manual Configuration* configure: 1. *Issuer* (Required) - The issuer must be OpenID Connect compliant. 2. *JSON Web Key Set URI* (Required) - Choose *Check for Metadata* button. If the entered issuer is verified as OpenID Connect compliant, the JSON Web Key Set URI will be retrieved automatically. Otherwise, you need to explicitly specify the *JSON Web Key Set URI* in the field. 3. *Refresh Interval* (Optional) - Refreshes the URI automatically if it is older than the selected interval. Choose from: • 24 hours (default choice) • 12 hours
Choose *Issuer Configuration* > *Corporate Identity Provider* > radio-button. **Note** When you choose *Corporate Identity Provider* radio-button, the *Manual Configuration* section is not configurable.	*Name* - (Required) Choose from OpenID Connect compliant corporate identity providers.

Field	Notes
General	1. *Subject* (Required) - The sub (subject) that is expected in the token. → Tip If you want to use an OAuth 2.0 token from a corporate identity provider as client credentials for an OpenID Connect application in Identity Authentication, and your OAuth client in the corporate identity provider belongs to a pre-configured application, the subject in the token is the Object ID of that pre-configured application. 2. *Audience* (Optional) - The `audience` claim of the identity provider. 3. `API Permission Groups` (Optional) - The field is enabled only when the *Provided APIs* option is configured. For more information, see Provide APIs for Consumption by Other Applications [page 2891].

- (For OpenID Connect-based JWT client tokens) Choose the *Add* button for *Configure Trust by URI* and provide the required info in the popup:

Configure Trust by URI

Field	Notes
Description	(Optional) You can provide information about the URI here.
URI	(Required) The JSON Web Key Set (JWKS) URI of the trusted party.
Refresh Interval	(Optional) Refreshes the URI automatically if it is older than the selected interval. Choose from: • 24 hours (default choice) • 12 hours
API Access	ⓘ Note This section is read-only. The predefined choice is OpenID.
API Permission Groups	(Optional) `API Permission Groups` field is enabled only when the *Provided APIs* option is configured. For more information, see Provide APIs for Consumption by Other Applications [page 2891].

1.7.1.14.2 Risk-Based Authentication for an Application

Use risk-based authentication to control user access to applications. Define authentication actions based on conditions like IP ranges, user groups, authentication methods, user types, email domains, and corporate attributes.

> → Tip
>
> Risk-based authentication is often confused with conditional authentication.

- Risk-based authentication configures the security level or authentication method you require users to use.
- Conditional authentication configures which identity provider authenticates your users.

Both use similar conditional criteria, such as IP ranges, groups, and user types. However, they serve different purposes in the authentication flow. Conditional authentication happens first to route users to the correct identity provider. Risk-based authentication then determines the security requirements after the identity provider is selected.

For more information about conditional authentication, see Configure Conditional Authentication for an Application [page 2076].

Configure Risk-Based Authentication for an Application [page 2007]
You can define rules for authentication according to different risk factors and apply actions like *Allow*, *Deny*, and *Two-Factor Authentication*.

Create a New Rule [page 2010]
You can create rules for authentication according to different risk factors.

Examples for Risk-Based Authentication Scenarios [page 2014]
Example scenarios for configuring risk-based authentication for an application.

1.7.1.14.2.1 Configure Risk-Based Authentication for an Application

You can define rules for authentication according to different risk factors and apply actions like *Allow*, *Deny*, and *Two-Factor Authentication*.

⚠ Restriction

Not supported for technical communication in OpenID Connect (OIDC) flows.

Authentication Rules

The created rules are displayed sorted by priority. When a user tries to access the application, the rules evaluate if the user meets the criteria of the rule. The evaluation starts with the rule with the highest priority, until the criteria of a rule are met. If the criteria of a rule are met, the rest of the rules aren't evaluated.

Default Authentication Rule

If none of the authentication rules meets the criteria, the default authentication rule is applied. For the default authentication rule, you can configure a *Default Action*, which can be *Allow*, *Deny*, or *Two-Factor Authentication*.

ⓘ Note

If *Two-Factor Authentication* is selected, additionally, you must specify the two-factor method or methods for the user.

The rule is valid for any *IP range*, *Forwarded IP Range*, *Group*, *Authentication Method*, or *User Type*.

Prerequisites

- (For *RADIUS Server Two-Factor Authentication*) You have requested this feature. For more information how to request and configure RADIUS server in Identity Authentication, see Configure RADIUS Server Settings (Beta) [page 2192].
- (For *SMS Two-Factor Authentication*) You have an account in Sinch Service. You have configured Sinch Service in the administration console for SAP Cloud Identity Services. For more information, see Configure Sinch Service in Administration Console [page 2051].

  > ⓘ Note
  >
  > Sinch Verification account is purchased separately. It isn't part of the Identity Authentication contract.

- (For *Email OTP Code*) An Email OTP Code template for the respective languages must exist in the tenant to apply the email OTP code method. If the template does not exist, the user will see the option but when choosing it, the following message will appear: "Sorry, but you are currently not authorized for access". For more information how to add email templates, see Edit or Add an Email Template Set [page 2289].

Context

> → Tip
>
> We recommend you to enable the back-up channels. Thus, the users can use the option as an alternative when they don't have access to the TOTP device or application.. For more information, see Enable Back-Up Channels to Send Passcode for Deactivation of TOTP Two-Factor Authentication Devices [page 2156].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the list item of the application that you want to edit.

   > ⓘ Note
   >
   > If you do not have a created application in your list, you can create one. For more details, see Related Information.

   > ⚠ Caution
   >
   > The list also includes the `Administration Console` application. If you enable risk-based authentication for that application, make sure that you, as a tenant administrator, meet the authentication rules and the default authentication rule. Otherwise when you log out of the administration console you will not be able to log in it again if you don't meet the rules.
   >
   > If `Administration Console` is not in the list of the applications you may request it. To do this, report an incident with a subject on SAP Support Portal Home under the component `BC-IAM-IDS`.

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, choose *Risk-Based Authentication*.
6. **Optional:** Configure the authentication rules. To configure the authentication rules, choose one of the following:

Option	Description
Create a new rule	See Create a New Rule [page 2010]
Edit an existing rule	Choose the icon next to the rule you want to edit.
Delete an existing rule	Choose the delete icon next to the rule you want to delete.
Reprioritize rules	Use the arrows to reprioritize the rules.

> ### Note
>
> By default any user can log on from any IP.

7. **Optional:** Configure the *Default Action*:
   - *Allow* - Any user can log on from any IP. This is the default choice.
   - *Deny* - Nobody can log on.
   - *Two-Factor Authentication* - A drop-down appears when this choice is selected. You must specify the two-factor authentication method or methods for the end user.
8. Save your changes.

   Once the application has been updated, the system displays the message `Authentication rules updated`.

Task overview: Risk-Based Authentication for an Application [page 2006]

Related Information

Create a New Rule [page 2010]
Examples for Risk-Based Authentication Scenarios [page 2014]
SAP Cloud Identity Services Application Directory

1.7.1.14.2.2 Create a New Rule

You can create rules for authentication according to different risk factors.

Context

Each rule contains the following information:

- **Authentication Action**
  This action is performed if the rule conditions meet the defined criteria.
  You can choose one of the following authentication actions:
  - *Allow*
    Identity Authentication allows the authentication of the user in accordance with the rule conditions.
  - *Deny*
    Identity Authentication denies the authentication of the user in accordance with the rule conditions.
    You can set this action for a test application for example, or before an application goes live.
    As long as this rule is valid, when users try to log on to the application, they get the following message: *Sorry, but you are currently not authorized for access*.
  - *Two-Factor Authentication*

    > ⓘ Note
    >
    > If *Two-Factor Authentication* is selected, additionally, you must specify the two-factor method or methods for the user:
    > - *TOTP Two-Factor Authentication*
    >   Identity Authentication asks two factors to authenticate the user.
    >   If you set TOTP two-factor authentication, users are required to provide a time-based one-time password (TOTP) called a passcode in addition to their primary credentials. Users also have to install an authenticator application on their mobile devices to generate TOTP passcodes.
    >   TOTP passcodes are time-based and valid for one logon attempt only.
    > - *SMS Two-Factor Authentication*
    >   Identity Authentication asks two factors to authenticate the user.
    >   If you set SMS two-factor authentication, users are required to provide an SMS code sent to their mobile devices in addition to their primary credentials.
    >
    >   > → Remember
    >   >
    >   > To use *SMS Two-Factor Authentication*, you must have configured Sinch Verification in the administration console for SAP Cloud Identity Services. For more information, see Configure Sinch Service in Administration Console [page 2051].
    >   >
    >   > Users must have their mobile phone numbers verified. The tenant administrator can verify phone numbers manually in the administration console or via the SCIM API. For more information, see List and Edit User Details [page 2361] and Identity Directory API.
    >   >
    >   > If the user does not have a verified phone number, the number is verified during the first log on when SMS code is required. After the user provides user name and credentials, he or she should provide the phone number in the field and request a code. Then provide the

received code in the respective field and choose *Continue*. If the submitted code is correct, the user is allowed access, and the telephone number is verified.

- *Web Two-Factor Authentication*
  Identity Authentication asks two factors to authenticate the user.
  If you set web two-factor authentication, users are required to authenticate with a device such as the built in biometric scanners or USB, Bluetooth or Near-Field Communication (NFC) devices in addition to their primary credentials.
- *Email OTP Code*
  Identity Authentication asks two factors to authenticate the user.
  If you set *Email OTP Code*, users are required to provide the code sent to their email in addition to their primary credentials.

  > ⚠ Caution
  >
  > For security reasons, the Email OTP code is not a recommended two-factor authentication method. You may consider using some of the other methods instead.

  > ⓘ Note
  >
  > In the scenario, when self-registration is enabled and email verification is disabled for the application, if you set only *Email OTP Code* in the rule, users that have registered themselves in the application are required to provide an email OTP code when they activate their account. They provide the received code in the respective field and choose *Continue*. If the submitted code is correct, the user is allowed access, and the email is verified.

  > → Remember
  >
  > An Email OTP Code template for the respective languages must exist in the tenant to apply the email OTP code method. If the template does not exist, the user will see the option but when choosing it, the following message will appear: "Sorry, but you are currently not authorized for access".
  >
  > For more information how to add email templates, see Edit or Add an Email Template Set [page 2289].
- *RADIUS Server Two Factor Authentication*
  If you set *RADIUS Server Two Factor Authentication*, users are required to provide a RADIUS passcode in addition to their primary credentials. Users must have a RADIUS token (hard or soft) configured for them to generate passcodes. For more information about how to configure RADIUS server in Identity Authentication, see Configure RADIUS Server Settings (Beta) [page 2192].

> → Remember
>
> The *Authentication Action* filed is mandatory.

- *IP Range*
  Define a range of IP addresses that authentication requests to Identity Authentication can be sent from. The value has to be specified in Classless Inter-Domain Routing (CIDR) notation.

> ### Note
>
> By default the field is empty, meaning that any IP is allowed.

> ### Example
>
> Enter 123.45.67.1/24 to allow users to log on from any IP starting with 123.45.67.

If no IP range is defined, the rule is valid for all IP ranges.

- *Forwarded IP Range*
  Define a range of IP addresses for the original IP addresses that authentication requests to Identity Authentication can be sent from. The value has to be specified in Classless Inter-Domain Routing (CIDR) notation.

  > ### Caution
  >
  > This range configuration is used in scenarios where authentication requests to Identity Authentication are made by a proxy server on-behalf of the user/client.
  >
  > Configuring the *Forwarded IP Range* for the client/user IPs requires configuring the IP Range for the proxy server IP address(es), that directly communicates with Identity Authentication, first.
  >
  > Identity Authentication expects the client IP to be sent by the proxy server in the **X-Forwarded-For** header of the authentication request.

  > ### Remember
  >
  > Identity Authentication does not have control over the involved proxies and their number, participating in the request between the client/user and Identity Authentication and whether these proxies behave according to the scenario. Therefore it is not guaranteed that the client IP address is sent in the above mentioned header alongside the IP addresses of the proxies (if any) to Identity Authentication.

- *Authentication Method*
  Specify the authenticating method, which the authenticating user has to use. If no method is selected, the rule is valid for any of the methods.
  You can choose from the following:
  - *Client Certificate*
  - *SPNEGO*
  - *User Name and Password*
  - *Token*
  - *Social Identity Provider*
  - *Trusted IdP SAML Assertion*

  > ### Note
  >
  > If the user has an active session with any of the methods, and that method is included in the rule, they can access the application without the need for additional authentication.

- *User Type*
  Specify the type, which the authenticating user must have. If no user type is selected, the rule is valid for any of the types.

- *Group Type*
  - Cloud Group - A group that is created in the Identity Directory of Cloud Identity services. This is the default choice. For more information about the Identity Directory groups, see Groups [page 514].
  - On-Premise Group - A corporate user store group.
- *Group*

  > **Restriction**
  >
  > The administrator must be assigned the *Manage Groups* role or be part of a policy that allows reading groups to be able to view the groups in the list. For more information, see Edit Administrator Authorizations [page 2309] or Configure Group Authorizations [page 2320].

  Specify a cloud or on-premise group, which the authenticating user has to be a member of. If no group is selected, the rule is valid for all users.
  If the rule is valid for an on-premise group, type in the name of the corporate user store group, for which this rule should be valid.
  The cloud groups have to be configured in the administration console for SAP Cloud Identity Services. For more information, see Managing Groups [page 2393].
- *Corporate Attribute*
  Specify an attribute from the corporate identity provider (IdP) assertion, based on which the rule action will be applied.
  The rule must include the attribute name and value. It is valid only when the specified name and value are found in the assertion from the corporate IdP.

  > **Note**
  >
  > For this rule, the *Apply Application Configurations* option of *Identity Federation* must be enabled. For more information, see Configure Identity Federation [page 2614].
- *Email Domain*
  Specify a domain for the email of the authenticating user.

The fields *IP Range*, *Forwarded IP Range*, *Group*, *Authentication Method*, and *User Type* are not mandatory, but at least one of them has to be specified.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the list item of the application that you want to edit.

   > **Note**
   >
   > If you do not have a created application in your list, you can create one. For more details, see Related Information.

   > **Caution**
   >
   > The list also includes the `Administration Console` application. If you enable risk-based authentication for that application, make sure that you, as a tenant administrator, meet the

> authentication rules and the default authentication rule. Otherwise when you log out of the administration console you will not be able to log in it again if you don't meet the rules.
>
> If `Administration Console` is not in the list of the applications you may request it. To do this, you need to report an incident with a subject on SAP Support Portal Home under the component `BC-IAM-IDS`.

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, choose *Risk-Based Authentication*.
6. Choose *Create Rule*.
7. Fill in the fields on the *New Risk-Based Authentication Rule* window.
8. Choose *Create*.
9. Save your changes.

Task overview: Risk-Based Authentication for an Application [page 2006]

Create a New Application [page 1922]

1.7.1.14.2.3 Examples for Risk-Based Authentication Scenarios

Example scenarios for configuring risk-based authentication for an application.

Example 1 (Setting TOTP Two-Factor Authentication)

Donna Moore is an administrator of company A. She wants to configure Identity Authentication to always ask the company employees for a password and a TOTP passcode (two-factor authentication) to log on to a *Leave Request* application. For this purpose, Donna sets only a *Default Action*:

Default Authentication Rule

Default Action: `Two-Factor Authentication`

Two-Factor Methods: `TOTP`

Michael Adams is an employee of company A and as such he wants to create a leave request. To log on to the Leave Request application, he provides his password. After that he is prompted to activate a mobile device and to provide a second factor for authentication (a passcode generated by an authenticator app on his mobile device). Two factors are required regardless of whether Michael is in the corporate network or on a business

trip. Michael's manager, Julie Armstrong, receives a notification that Michael has created a leave request. She approves it by logging on to the application with two factors (password and passcode generated by her mobile device).

Example 2 (Setting SMS Two-Factor Authentication)

Donna Moore is an administrator of company A. She wants to configure Identity Authentication to always ask the company employees for a password and an SMS code (two-factor authentication) to log on to the *Corporate Page*. For this purpose, Donna first configures Sinch Service in the administration console for SAP Cloud Identity Services. Then in the *Risk-Based Authentication* section in the administration console, he sets only a *Default Action*:

Default Authentication Rule

Default Action: `Two-Factor Authentication`

Two-Factor Methods: `SMS`

John Miller is an employee of company A and as such he wants to access the corporate page of the company. He is prompted to provide two factors (a password and the SMS code sent to his mobile device) to log on to the corporate page. John Miller has his mobile phone verified, so he can receive SMS codes. Two factors are required regardless of whether Miller is in the corporate network or at home.

Example 3 (SPNEGO)

Donna Moore is an administrator of company A. She wants to configure Identity Authentication to allow employees to access the *Leave Request* application from the corporate network with SPNEGO, and from any other network with passcode. All IPs in the company start with 189.101. She would also like to create a rule for the managers to access the application with two authentication factors. In addition, she wants to restrict the access to all the users with type *Customer*. For this purpose, Donna creates the following rules:

Authentication Rules

Authentication Action	IP Range	Group	Authentication Method	User Type
Deny	Any	Any	Any	Customer
Allow	189.101.112.1/16	Employees	SPNEGO	Any
TOTP Two-Factor Authentication	Any	Employees	Any	Any
TOTP Two-Factor Authentication	Any	Managers	Any	Any

Default Authentication Rule

Default Action: `Deny`

Michael Adams, as an employee of company A, accesses the application in his office and logs on with SPNEGO. When he is on a business trip, he can create leave requests by providing two factors. The two factors are SPNEGO and a passcode generated by an authenticator app on his iPhone. Michael's manager, Julie Armstrong, receives a notification that Michael has created a leave request. She approves it by logging on to the application with TOTP Two-Factor Authentication (a password and a passcode generated by her Android phone). Donna Moore, a customer of company A, tries to access the Corporate Portal, and receives a message that she is not authorized for access.

Example 4 (Setting Web Two-Factor Authentication)

Donna Moore is an administrator of company A. She wants to configure Identity Authentication to always, ask the company managers for a password and a web two-factor authentication to log on to a *Leave Request Approval* application. For this purpose, Donna sets only a *Default Action*:

Default Authentication Rule

Default Action: `Two-Factor Authentication`

Two-Factor Methods: `Web Authentication`

Michael Adams is an employee of company A and he creates a leave request. Michael's manager, Julie Armstrong, receives a notification that Michael has created a leave request. To log on to the Leave Request Approval application, she provides her password. After that Julie is prompted to activate a security key as a second factor for authentication. Two factors are required regardless of whether Julie is in the corporate network or on a business trip.

Julie he approves the leave request by logging on to the application with two factors (password and fingerprint).

Example 5 (Setting more than one Two-Factor Authentication method)

Donna Moore is an administrator of company A. She wants to configure Identity Authentication to always ask the company managers for a second factor in addition to their password. She wants to allow the managers to choose between a TOTP and a web two-factor authentication to log on to a *Leave Request Approval* application. For this purpose, Donna sets the *Default Action* to *Two-Factor Authentication* and configures the *Two-Factor Methods*:

Default Authentication Rule

Default Action: `Two-Factor Authentication`

Two-Factor Methods: `TOTP`; `Web Authentication`

Michael Adams is an employee of company A and he creates a leave request. Michael's manager, Julie Armstrong, receives a notification that Michael has created a leave request. To log on to the application *Leave Request Approval* she provides her password. After that she is prompted to choose the two-factor authentication method. She chooses a security key as a second factor for authentication.

Julie approves the leave request by logging on to the application with two factors (password and fingerprint).

In addition to Julie's approval, the leave request must also be approved by the HR Manager of the company, John Miller. To log on to the *Leave Request Approval* application John provides his password. After that he is also prompted to choose the two-factor authentication method. John chooses TOTP. Now, he is prompted to provide a TOTP code from his device. After providing it, he is granted access to the app and approves the leave request.

Two factors are required regardless of whether Julie and John are in the corporate network or on a business trip.

Example 6 (Define IP Addresses)

Donna Moore is the security administrator of company A. She wants to configure Identity Authentication to allow employees to access the company's Critical Infrastructure Depot only from its two office locations. All other access attempts should be denied. The two office locations are with the following IP ranges: the headquarters uses IPs starting with 203.0.113, and the branch office uses IPs starting with 198.51.100. For this purpose, Donna creates the following rules:

Authentication Rules

Authentication Action	IP Range	Group	Authentication Method	User Type
Allow	203.0.113.0/24	Employees	Default	Any
Allow	198.51.100.0/24	Employees	Default	Any

Default Authentication Rule

Default Action: `Deny`

Michael Adams is a security specialist of company A. When he tries to access the Critical Infrastructure Depot from the headquarters office, he successfully logs on with his credentials because his IP address falls within the allowed range. However, when Michael travels and attempts to access the depot from a hotel, he receives a message that access is denied.

Julie Armstrong, a regional security manager of company A, works from the branch office. She can access the Critical Infrastructure Depot without issues because her IP address is also within the allowed range.

John Miller, an employee at Company A, works remotely from home two days per week. He tries to access the Critical Infrastructure Depot from his home office location and receives a message that access is denied. He can access it without problems while he is in the office.

Create a New Rule [page 2010]

1.7.1.14.3 Configure Concurrent User Access to the Application

Tenant administrator can allow or restrict user access to an application from one or more browsers or devices.

Context

With the concurrent user access option, you as a tenant administrator can configure the system so that based on the requirements the application can allow or restrict multiple sign-ins by one and the same user.

The concurrent access offers three options:

- **Allow**
  No restrictions are applied. The user can sign in from multiple devices and browsers. This is the default setting.
- **Warning**
- The user can sign in from only one device or browser at a time during the lifetime of the identity provider (IdP) session. If other sessions exist, the user receives a message and will have the option to terminate the other session and sign out.
  To guarantee a consistent behavior for the application, the application session should have the same timeout as the IdP session. For more information about the session management, see Configure Session Timeout [page 2170].

  > → Remember
  >
  > If the user chooses the option *Sign Out and Continue*, they can still choose to continue with the new session without terminating the previous one. The system will not terminate the session automatically. If you want to restrict concurrent access, then you should use the *Error* option to terminate the other session and sign out.

  > ⚠ Caution
  >
  > If you have configured a *Warning* concurrent user access option, you must also have a Single Logout Endpoints (SLO) URL with a SOAP binding added for the SAML 2.0 application. Otherwise if a user chooses to sign out and continue to new session, an SLO request for the old session won't be sent to the application.. For more information, see Configure SAML 2.0 Service Provider [page 1941].

- **Error**
  The user can sign in from only one device or browser at a time during the lifetime of the identity provider (IdP) session. When the user tries to sign in from another device or browser, they see an error message.
  The user can sign out from the unwanted sessions via the profile page. The option is available at *Profile Page* > *Sessions and Tokens* > *Active Sessions*.
  To guarantee a consistent behavior for the application, the application session should have the same timeout as the IdP session. For more information about the session management, see Configure Session Timeout [page 2170].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, choose *Concurrent Access*.
6. Set the radio button for the users you want to allow to log on:
   - Allow
   - Warning
   - Error

   If the application is updated, the system displays the message `Application <name of application> updated`.

1.7.1.14.4 Always Require Password from Users

Always require users to provide password when accessing an application.

Context

By enabling the *Force Authentication* option users must always provide a password when accessing an application. The configuration is per application. The option is switched off by default.

Force authentication can be enabled for both OpenID Connect and SAML 2.0 applications.

> **Note**
>
> In the context of a corporate identity provider scenario, if an application requires force authentication, users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

To enable force authentication for an application, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Enable the *Force Authentication* option under *Authentication*.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

1.7.1.14.5 Enable or Disable Social Sign-On for an Application

Social sign-on allows users to link their Identity Authentication accounts with social network accounts.

> ⓘ Note
>
> The content in this section is not relevant for China (Shanghai) region.

To link the accounts, users have to choose the social provider button on the logon page of a cloud application. When authenticated via their social identity provider, users are prompted to allow their accounts to be linked with the social network accounts. After this initial setup, users can log on to the application without additional authentication.

Prerequisites

You have set the social providers on tenant level. For more information, see Configuring Social Identity Providers [page 2505].

Context

Identity Authentication allows account linking with the following social providers:

- Apple
- Facebook
- Google
- LinkedIn
- X

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, enable or disable social sign-on.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Results

With *Social Sign-On* users can log on to the application via one of the social providers. They can see this option on the logon page. Which social identity providers logos appear on the logon page of the application depends on the configurations you have made. For more information, see Configuring Social Identity Providers [page 2505].

Related Information

Create a New Application [page 1922]

1.7.1.14.6 Enable or Disable FIDO2 Biometric Authentication for an Application

Allow users to log on to applications with biometric information without the need to provide username and password.

Context

By configuring FIDO2 biometric authentication, users can log on to applications with their biometric information such as fingerprint, face scan, etc., without the need to provide username and password.

Once the biometric authentication is enabled, the user can choose the *Biometric Authentication* button on the logon page. If the user has a configured biometric authentication device, the logon process will require authentication with the registered device. If biometric authentication isn't configured, the user is required to log on with username and password first. After that he or she should visit their profile page and register a device in the *WEB Two-Factor Authentication* section. This is a onetime configuration.

> **Note**
>
> The user can add more than one device, but can't add a device that has already been added, either for biometric authentication or for two-factor authentication. He or she can remove a device from the list on the profile page. The removal of a device is password protected.

Identity Authentication supports the following:

Device	OS	Browser
Face ID	Latest iOS	• Latest Chrome • Latest Safari
Touch ID	Latest macOS	• Latest Chrome • Latest Safari
Windows Hello	Windows 10	• Latest Edge • Latest Chrome

The user can manage the biometric authentication settings at the profile page.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, enable or disable biometric authentication.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Next Steps

Enable the *Credential change* security alert emailing to inform the user when a biometric authentication device is activated or deactivated. For more information, see Send Security Alert Emails [page 2209].

Related Information

Create a New Application [page 1922]

1.7.1.14.7 Enable Users to Generate and Authenticate with Certificates

Allow users to generate and authenticate with certificates.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

By enabling certificate generation and authentication for the users, they can log on to applications with the generated certificate without the need to provide username and password.

The tenant administrator can configure the system to allow the following types of users to generate their own certificates via the profile page and to authenticate with them:

- *Public*
- *Customer*
- *Partner*
- *Employee*

The certificate generation and authentication is disabled by default for all user types. When you allow it for a user type, the user of this type should go to the profile page and generate a certificate for authentication. Once the certificate is generated, it's downloaded to the user's system. When the user imports it to the certificate store or browser, the newly generated certificate is ready for authentication. When the user navigates to the logon page of the application, he or she is automatically authenticated with the certificate. If the authentication fails, the user is prompted to provide username and password.

> ⚠ Caution
>
> If you have an already configured X.509 client certificate used for user authentication, the users won't be able to authenticate with their own certificates generated via the profile page, and vice versa.

To allow certificate generation and authentication, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Certificate Authentication* list item.
4. Use the slider next to a user type to enable certificate authentication.

   If the operation is successful, you receive a confirmation message.

Next Steps

Enable the *Credential change* security alert emailing to inform the user when a certificate generated or removed. For more information, see Send Security Alert Emails [page 2209].

1.7.1.14.8 Configure User Access to the Application

You can configure public access to the application allowing self-registration, or you can restrict the access to existing users or users registered by an application.

Context

You can configure the application to restrict access to specific users only. The following access configurations are possible:

- **Public**
  All users are allowed to log on. Unregistered users start the self-registration process by choosing the *Register Now* link on the logon page.

  > ⓘ Note
  >
  > You have to add as trusted the domains for those applications that allow self-registration to the users. For more information, see Configure Trusted Domains [page 2173].

  > → Tip
  >
  > You can protect the self-registration form against machine registrations via reCAPTCHA. For more information, see Protecting Application Forms with Google reCAPTCHA [page 2056]. The content in this section is not relevant for China (Shanghai) region.

- **Internal** - this is the default setting.
  Only existing users are allowed to log on. Users that are not in the user store of Identity Authentication cannot log on.
  When this option is chosen, self-registration is not possible.

  > → Tip
  >
  > For more information how to add new users in the user store of Identity Authentication, see Create a New User [page 2357].
  >
  > You can also import new users in Identity Authentication via a CSV file. For more information, see Import or Update Users for a Specific Application [page 2348].

- **Private**
  Only users registered by an application can log on. To register users for a specific application, you have to import these users via a CSV file. For more information, about the user import, see Import or Update Users for a Specific Application [page 2348].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, choose *User Application Access*.
6. Set the radio button for the users you want to allow to log on:
   - Public
   - Internal
   - Private
7. Save your selection.

   If the application is updated, the system displays the message `Application <name of application> updated`.

Related Information

Create a New Application [page 1922]
Risk-Based Authentication as an Alternative to Restrict User Access Option in Identity Authentication Service

1.7.1.14.9 Enable Email Verification

Tenant administrators can configure applications to require verification of the user's email address.

Context

Applications can be configured to require users to have their email addresses verified before they can log on. If you want to make sure that a user has a valid email address, even if the email address has not been verified, you should enable the email verification option in the administration console for SAP Cloud Identity Services.

> ### Note
>
> You can check whether the user's email address has been verified by choosing *User Management* > *Details* > *Personal Information* in the administration console. The *Email Verified* box is checked if the

user's email address has been verified. For more information about the user details, see List and Edit User Details [page 2361].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, enable *Email Verification*.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Results

When the user tries to log on, he or she is asked to verify the email address first. To verify the email, the user must click the link sent to him or her. Once the email address has been verified, the user can log on to the application.

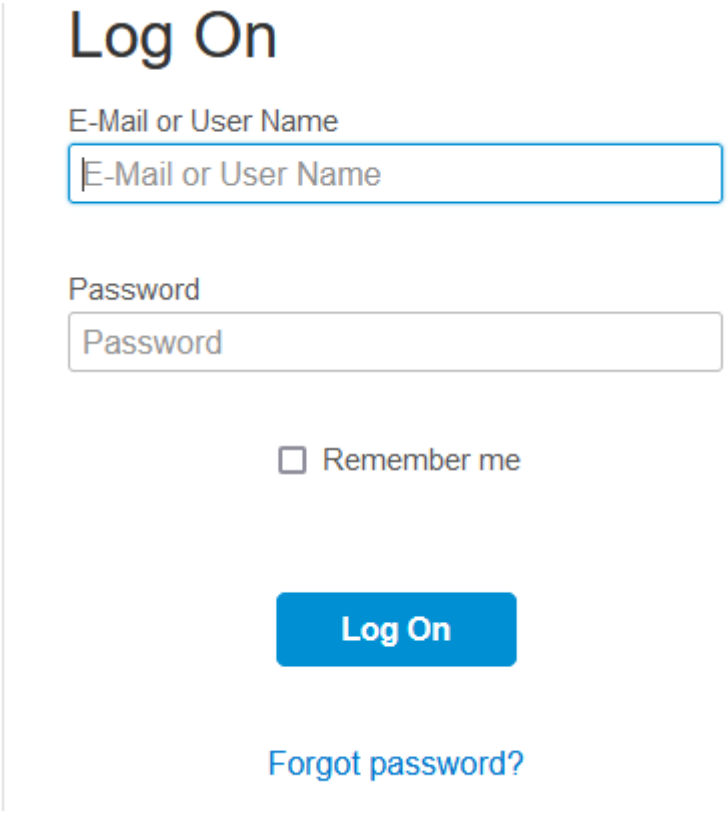
> → Remember
>
> Identity Authentication can send to the user up to three emails (forgot password, reset password, locked password, email verification) per 24 hours.
>
> If the user must receive more than three emails, the administrator must reset the counter for email sending first. For more information, see Reset Counter for Email Sending [page 2383].

1.7.1.14.10 Configure the Remember Me Option

Tenant administrators can configure the *Remember me* option as visible or hidden, and checked or unchecked.

Context

With the remember me option, a cookie is sent to the browser so the users can log on to an application without the need to provide their credentials every time they access it. The default configuration for the remember me option is: visible and unchecked. The default validity for remember me is 3 months. If the default configuration is preferred, users see the remember me option on the logon screen:



You can change the default configuration for the remember me option via the administration console for SAP Cloud Identity Services. The following options are available:

Visible	Checked	Validity	Notes
Yes	No	• 1 month • 3 months - the default choice • 6 months • 12 months • 24 months • 36 months	The default configuration. Users see the option on the logon screen as unchecked. The user is asked every time for credentials by the application. The validity of the cookie is as configured by the administrator. The default validity is 3 months.
Yes	Yes	• 1 month • 3 months - the default choice • 6 months • 12 months • 24 months • 36 months	Users see the option on the logon screen as checked. A cookie is sent to the user's browser at first logon. It automatically logs the user on next time the application is accessed from the same browser on the user's local computer. The validity of the cookie is as configured by the administrator. The default validity is 3 months.
No	No		Users don't see the option on the logon screen.
No	Yes	• 1 month • 3 months - the default choice • 6 months • 12 months • 24 months • 36 months	Users don't see the option on the logon screen, but the option is checked for them. A cookie is sent to the user's browser at first logon. It automatically logs the user on next time the application is accessed from the same browser on the user's local computer. The validity of the cookie is as configured by the administrator. The default validity is 3 months.

Note

Remember me tokens generated for an application are valid for all applications in the tenant. If the option is enabled, the cookie validity of the first application that is accessed by the user is taken into consideration and all other applications have the same cookie validity despite their configuration in the administration console.

Restriction

The remember me option is supported only when Identity Authentication is set as the default local identity provider for the application. When the authentication is done via a corporate identity provider no cookie is sent to the user's browser.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

3. Choose the *Authentication and Access* tab.
4. Under *Authentication*, choose *Remember Me Settings* option is and configure the options according to your needs.
5. Save your changes.

1.7.1.15 Configure Logo

You can upload and configure a custom logo for your applications. Furthermore, you can remove a configured logo and leave the display name only as a title for the application.

The logo is displayed on the application's logon page and can be included into the emails sent to users.

1. Upload Logo in Administration Console [page 2030]
   You can upload a custom logo in the administration console by uploading an image and use it for your applications.
2. Add Logo for an Application [page 2032]
   Configure a custom logo for a specific application by choosing it from the list of your uploaded images in the administration console.

Related Information

Configuring Email Templates [page 2282]

1.7.1.15.1 Upload Logo in Administration Console

You can upload a custom logo in the administration console by uploading an image and use it for your applications.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Logos* tile.
3. Choose *Add*.
4. Provide a name for the logo in the dialog and choose *+Add*.
5. To upload a logo, choose *Browse* and select an image with the required format.

   You can use one of the following formats for the image: <name>.png, <name>.gif, <name>.jpeg, or <svg>.

   > ⓘ Note
   >
   > The image must be smaller than 100 KB and with a maximum size of 300x100.

   > ⚠ Caution
   >
   > If the image is of format <svg>, please make sure that the attribute `viewBox = "min-x min-y width height"` is present. For proper rendering the width and height values must be 100. For example, `viewBox="0 0 100 100"`
6. Save your configuration.

   > → Tip
   >
   > To remove an uploaded logo from the list, choose the *Delete* button and confirm your choice. Only logos that are not assigned to applications can be removed.

Task overview: Configure Logo [page 2030]

Next task: Add Logo for an Application [page 2032]

Related Information

Create a New Application [page 1922]

1.7.1.15.2 Add Logo for an Application

Configure a custom logo for a specific application by choosing it from the list of your uploaded images in the administration console.

Prerequisites

You have uploaded an image in the administration console. See Upload Logo in Administration Console [page 2030].

Context

The logo is displayed on the application's logon page and can be included into thee mails sent to users. You can also remove a configured logo and leave the display name only as a title for the application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *BRANDING*, choose *Logo*.
6. To set a custom logo for the application, choose *Edit*.
7. Choose the *Image* field and select an image from the list that appears.
8. Save your configuration.

   > → Tip
   >
   > To remove a configured logo, choose the *Remove* button and confirm your choice.
   >
   > When you are in *Edit* mode, the *Remove* button is hidden.

Task overview: Configure Logo [page 2030]

Previous task: Upload Logo in Administration Console [page 2030]

Related Information

Create a New Application [page 1922]

1.7.1.16 Display Application Name on Logon Page

This section shows you how to display or hide the name of the application from the logon page.

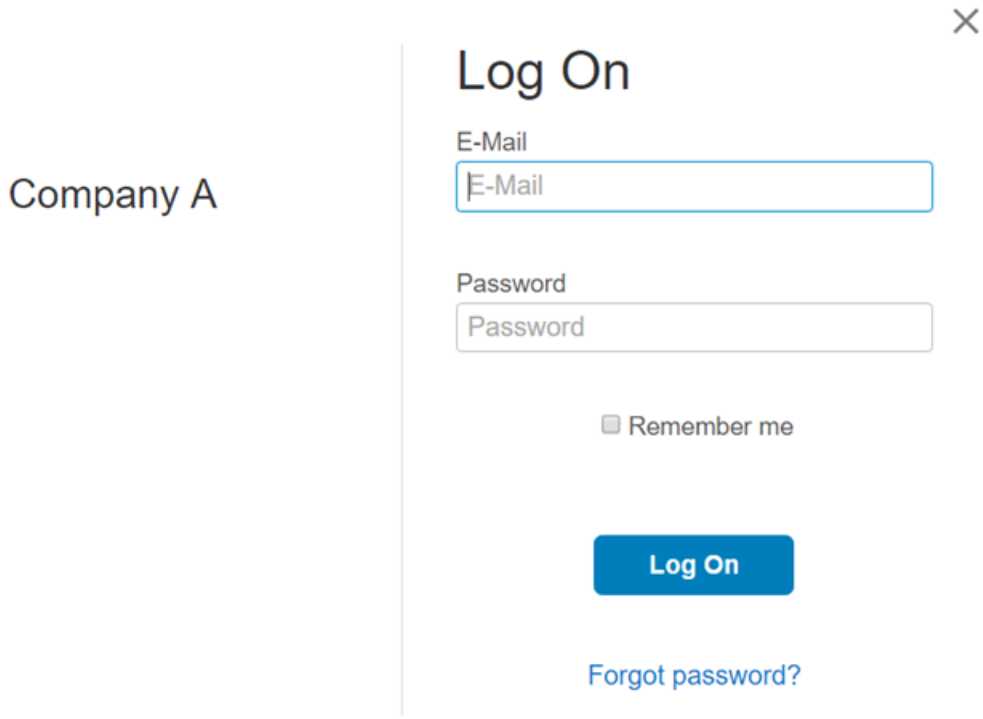
Prerequisites

You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The application's display name appears on the left side of the logon and registration pages of the applications that use Identity Authentication for authentication. You set this name when you first create your application in the administration console for SAP Cloud Identity Services, and you can change it later. For more information, see Create a New Application [page 1922] and Change an Application's Display Name [page 1934].

By default, the display name of the application is set to appear on the logon page.



> ⚠ Caution
>
> Be careful when you switch off the display of the application name. The users might not be sure which application they are providing their credentials for.

> → Tip
>
> Instead of leaving the left side of the logon page blank you can add an application's logo. For more information, see Configure Logo [page 2030].

To configure the appearance of the application's name on the logon page, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *BRANDING*, enable or disable the appearance of the application name on the logon page.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Results

Depending on your choice, the display name of the application is visible or hidden on the logon page.

1.7.1.17 Choose and Configure a Branding Style for an Application

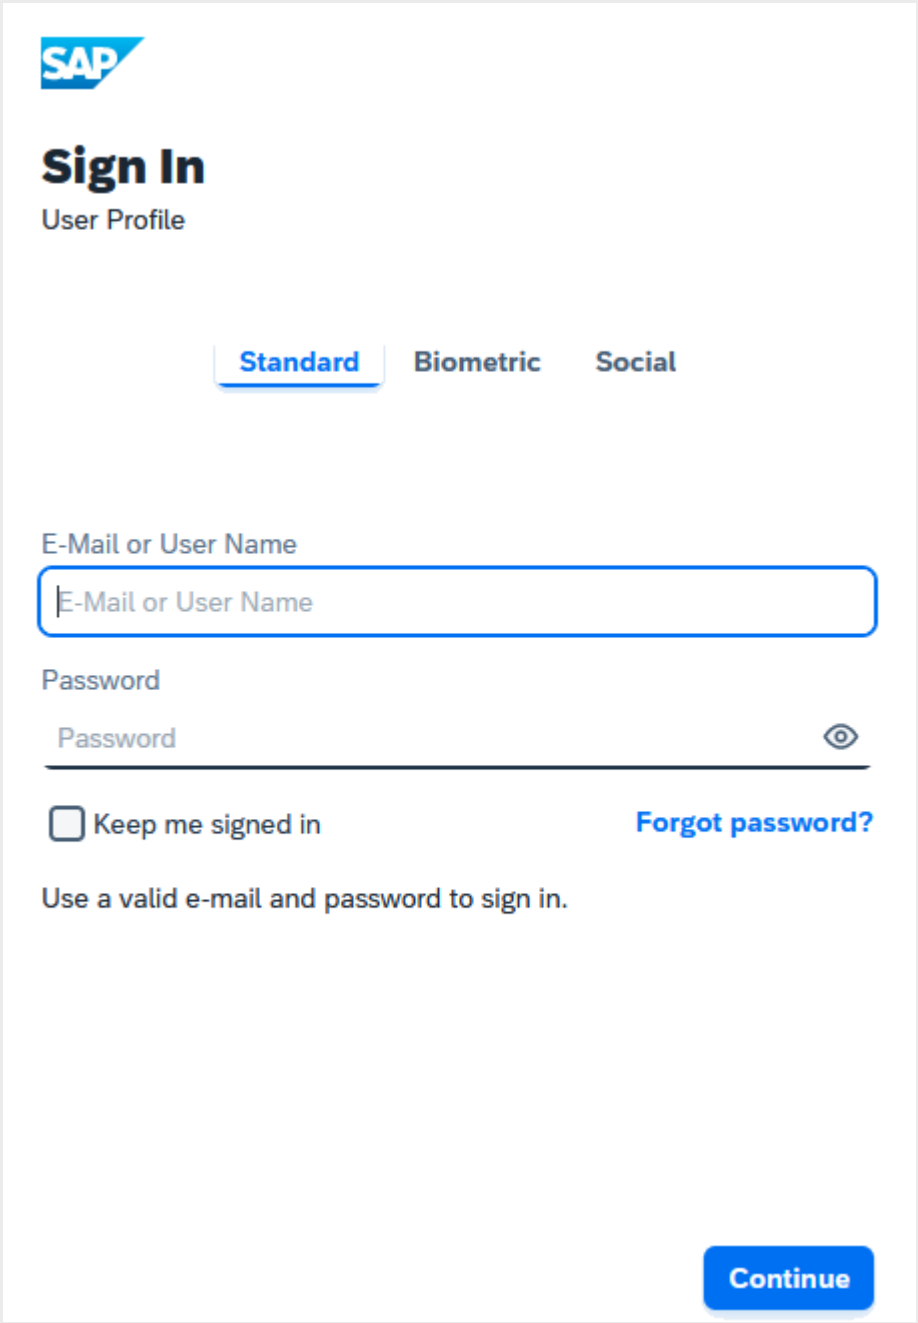
For the configuration of the branding style, you can choose a style for the end-user screens, such as sign-in, registration, upgrade. You can also customize the buttons on these screens.

Context

You can use one of the following themes and customize them:

- *Horizon*:
  - Standard - This predefined theme is an evolution of the SAP Fiori design system. It uses the Horizon theme for the end-user screens. To learn more about the theme, see SAP's UI Technologies supporting the new Horizon visual theme of SAP Fiori.
    You can customize the *Horizon* theme with instructions that appear on the sign in screen.

Example



Note

This is the default setting for all new tenants, and for all new applications (service providers) created after Oct 26, 2022 via the administration console, SCIM REST API, or by the Identity Authentication operators.

- Custom Advanced - You can do advanced customization of the end-user screens, by uploading a CSS file and assign that file to an application. The CSS file overrides the default CSS file of the Horizon theme.

- *Quartz*
  - Standard - This predefined theme includes white and brand blue coloring based on SAP Fiori's color palette.

    > **Note**
    >
    > This is the default setting for all tenants and applications created before Oct 26, 2022.

    Example

    
  - Custom Basic
    The custom basic theme allows you to configure a custom branding style for the buttons and information messages. It uses the Quartz theme for all other elements on the screens and error pages. For this configuration, you can customize:
    - the top and bottom background color of the button
    - the background color of the information message in the forms
    - the button's and information message's border line color
    - and the color of the button's text
  - Custom Advanced
    You can do advanced customization of the end-user screens, by uploading a CSS file and assign that file to an application. The CSS file overrides the default CSS file for the Quartz theme.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *Branding*, choose the *Branding Style* list item.
6. Choose your preferred theme and select one of the available options for it:

Theme	Customization
Horizon Theme	• *Standard* For more information about how to customize the theme with instructions that appear on the sign-in screen, see Add Instructions Section on Sign-In Screen [page 2133]. • *Custom Advanced*. For more information, see Use a Custom CSS [page 2040].
Quartz Theme	• *Standard* • *Custom Basic* - For more information, see Use a Custom Basic Quartz Theme [page 2039]. • *Custom Advanced*. For more information, see Use a Custom CSS [page 2040].

7. Save your configuration.

> **→ Tip**
>
> Skip this step if you already saved your configuration in **Step 6**.

Once the application has been changed, the system displays the message `Theme changed to <name of theme>`.

Use a Custom Basic Quartz Theme [page 2039]
Configure a branding style for the buttons and information messages for the Quartz theme.

Use a Custom CSS [page 2040]
Upload a CSS file and assign that file to an application for advanced customization of the end-user screens and the profile page for the Quartz or Horizon Theme.

1.7.1.17.1 Use a Custom Basic Quartz Theme

Configure a branding style for the buttons and information messages for the Quartz theme.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *Branding*, choose the *Branding Style* list item.
6. Select the *Quartz Theme*
7. Choose the *Custom Basic* radio button.
8. Configure the colors.

   To configure the colors, you can use the color picker or enter the color's hexadecimal value.

   See the table below for more information about the buttons and screens that can be customized.

Color Picker	Customized Area
Background Top Color	• button's background top color in all screens • information's message background color in the *Forget Password* screen
Background Bottom Color	• button's background bottom color in all screens • the button's background color when the mouse is hovered on it in all screens • information's message border color in the *Forget Password* screen
Border Color	the button's border color in all screens
Text Color	the text in the buttons in all screens

9. Save your selection

   Once the application has been changed, the system displays the message `Theme changed to <name of theme>`.

1.7.1.17.2 Use a Custom CSS

Upload a CSS file and assign that file to an application for advanced customization of the end-user screens and the profile page for the Quartz or Horizon Theme.

Context

To use a custom CSS for the application end-user screens and profile page, you must upload your custom CSS file in the administration console for SAP Cloud Identity Services and then assign that file to the application.

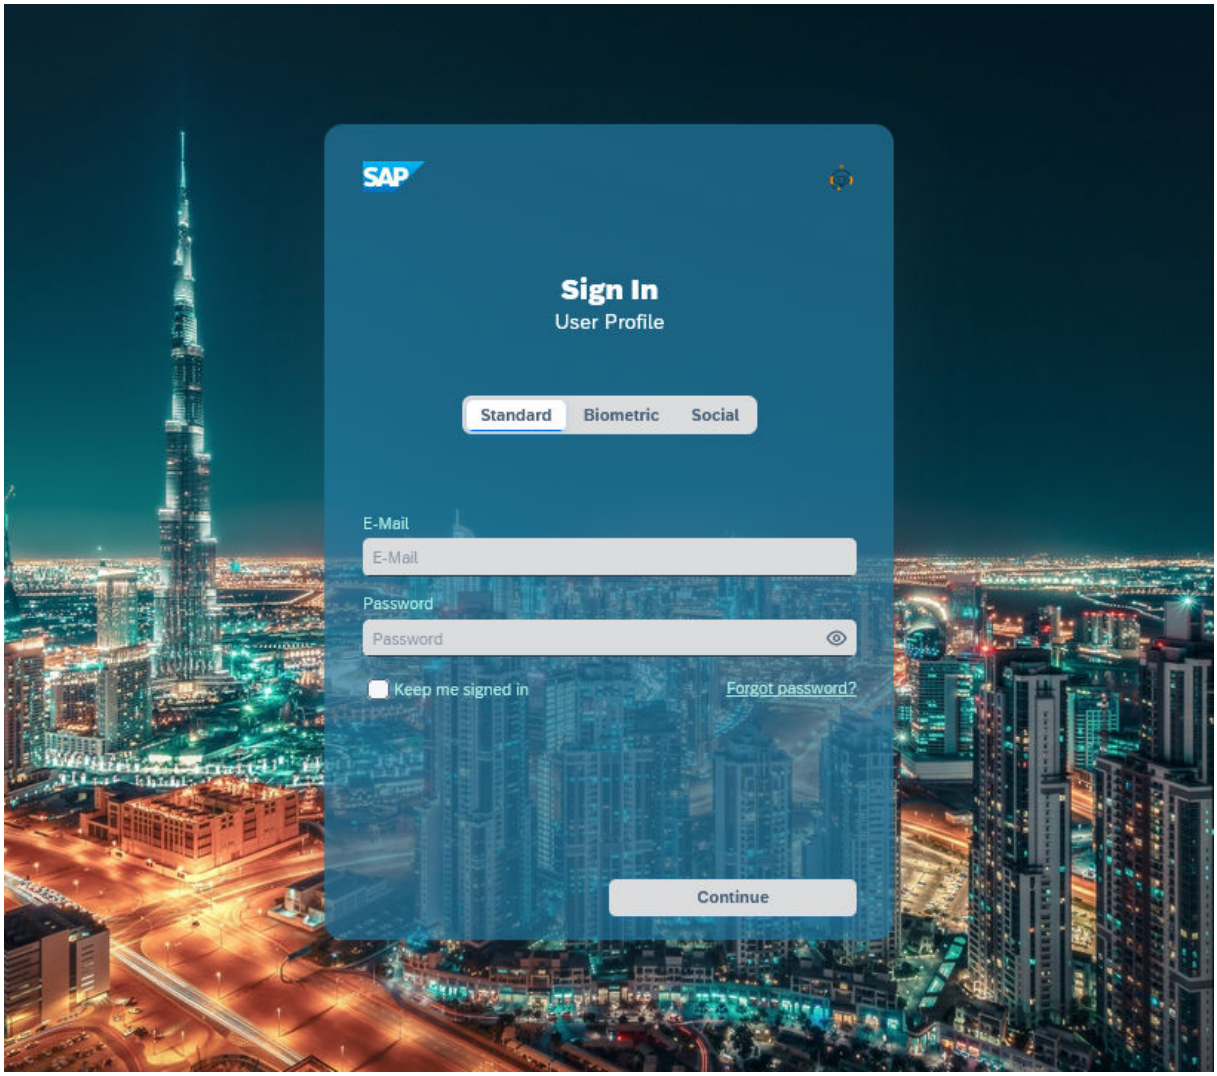
> ⚠ Caution
>
> When working with custom CSS documents or importing CSS documents from external sources, always consider the following safety guidelines:
>
> - *Validate Sources* - Before importing a CSS file from an external source, be sure that you trust the provider.
> - *Review Content* - Inspect the content of the external CSS file to ensure it doesn't contain any security vulnerabilities.
> - *Monitor Regularly* - Periodically review and update the imported CSS documents to prevent any potential security vulnerabilities.

- 1. Upload a Custom CSS File [page 2042]
- 2. Assign the Custom CSS File to an Application [page 2043]

Example

Horizon

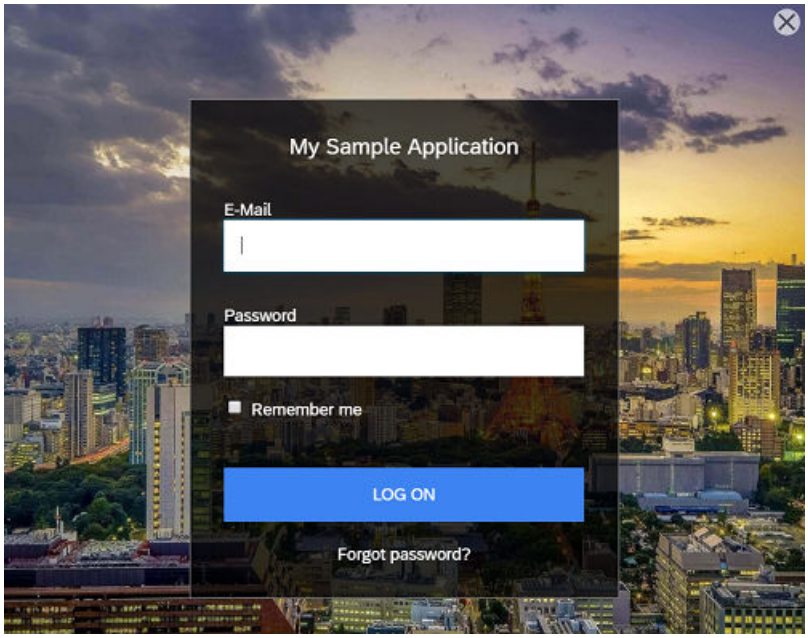
The Horizon-Example.zip contains a CSS file, which you can use to test the Custom CSS option for the Horizon theme. After you follow the procedures for uploading and assigning the example file, the resulting logon page will be:



> **Note**
>
> The background image, and the tenant and application logo are configured separately, and aren't part of the CSS file.

Quartz

The Example.zip contains a CSS file which you can use to test the Custom CSS option for the Quartz theme. After you follow the procedures for uploading and assigning the example file, the resulting logon page will be:



You can download the default CSS file for the Quartz theme at Default.zip.

1.7.1.17.2.1 1. Upload a Custom CSS File

Upload a Quartz or Horizon CSS file for custom end-user screens or the profile page.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Custom CSS* tile.
3. Choose the CSS style that you want to edit.

   > **Note**
   >
   > Type the name of the CSS style in the search field to filter the list items, or choose the CSS style from the list on the left.
   >
   > If you do not have a CSS style list, you can create one by choosing the *Add* button on the screen.

4. Browse for a CSS file and upload it for the respective theme.
5. Save your changes.

   Once the style has been saved, the system displays the message `<name of theme> updated`.

   You can update your custom CSS style as many times as you need. Only the last updated version is used.

   You can delete a CSS style. Select the CSS style and choose the *Delete* button to delete it.

> ⚠ Caution
>
> You can delete a CSS style, only if it is not assigned to an application. If it is assigned, you must assign a new style, and then delete it.

You can download the CSS file for further reference by choosing the *Download* button.

6. **Optional:** To preview the implementation of the CSS on the Sign-In page, copy the preview link and open it in a new private or incognito tab.

1.7.1.17.2.2 2. Assign the Custom CSS File to an Application

Assign the your CSS file to the application or profile page.

Context

Once you have a CSS file uploaded for your theme you can assign it to an application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *BRANDING*, choose the *Branding Style* list item
6. Select the theme:
   - *Horizon Theme*
   - *Quartz*
7. Choose the *Custom Advanced* radio button.
8. Select the style sheet that you want to apply.
9. Save your selection.

   Once the application has been changed, the system displays the message `Theme changed to <name of theme>`.

> → Remember
>
> The custom CSS file is combined with the default CSS file of Identity Authentication.

1.7.1.18 Enable or Disable Reload Parent Page Option

You can enable or disable the reload of the application's parent page after a successful logon.

Prerequisites

You have an SAML 2.0 application. The *Reload Parent Page Option* is not visible for OpenID Connect applications.

Context

The *Reload Parent Page* option specifies whether the application's parent page reloads or not after a successful logon via an overlay page.

> ⓘ Note
>
> By default the *Reload Parent Page* option is enabled. Disable the option if you would like to embed the logon page in your custom iFrame.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Branding and Layout* tab.
5. Under *LOGIN PAGE BEHAVIOR*, configure the *Reload Parent Page* option.

Once the application has been updated, the system displays the message `Application <name of application> updated`.

1.7.1.19 Define an Email Template Set for an Application

Tenant administrators can define the email template set that the application uses.

Context

Initially, the application uses a default template set with an English language version for all the templates in the set. This template set is named *Default*. If you want to use another email template set, assign it to the respective application.

> **Note**
>
> Both the HTML and TXT formats are included in the emails sent to a user. What the user sees, depends on the settings of his or her email client.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Branding and Layout* tab.
5. Under *EMAIL CONFIGURATIONS*, choose *Email Template Set*.
6. Select the radio button of the email template set the application will use.
7. Save your selection.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Next Steps

(Optional) Configure custom mail server. To use own mail server for the emails sent for the different application processes, you should configure your mail server in the administration console for SAP Cloud Identity Services.

For more information, see Configure Mail Server for Application Processes [page 2195].

1.7.1.20 Configure Registration and Upgrade Forms

In the administration console, you can configure which user attributes Identity Authentication sends to the service provider or client (relying party) to be displayed on application's registration and upgrade forms. After the user has filled in the form, the information from these attributes is recorded in the user's profile. This is why these attributes are also called profile attributes and are handled by the profile services.

> ⓘ Note
>
> The user ID attribute cannot be controlled by the user. Because of that it is not included on the registration and upgrade forms, but is available in the user's profile.

Context

To configure the profile attributes, you need to specify which personal, company, and contact information the application prompts the user to provide when registering or upgrading. The information that the user has to provide depends on the status of the attribute (required or optional). You configure which attributes are displayed as required or optional in the administration console for SAP Cloud Identity Services.

The list of the attributes includes:

PERSONAL INFORMATION

- `Salutation`
- `First Name`
- `Middle Name`
- `Last Name`

  > ⓘ Note
  >
  > The `Last Name` attribute is always required for user registration or upgrade, so it is not configurable.

- `Email`

  > → Remember
  >
  > The `Email` attribute is required for user registration or upgrade, and as so not configurable, if marked as required on tenant level. If `Email` is marked as not-required on tenant level, it becomes configurable, and must also be changed here.

- `Phone`

> **Note**
>
> The `Phone` attribute becomes required and not configurable for user registration or upgrade, when *Phone Verification via SMS* is enabled. For more information, see Configure Registration and Upgrade Forms [page 2046].
>
> If you disable *Phone Verification via SMS*, the `Phone` attribute remains required for user registration or upgrade. To make it optional, or remove it, follow the procedure in this document.

- `Street Address`
- `Street Address 2`
- `City`
- `Zip/Postal Code`
- `Country`

> **Note**
>
> The `Country` parameter is required when the `Zip/Postal Code` is filled in by the user in the registration form. For example, this is the situation when both `Zip/Postal Code` and `Country` are optional, and the user fills in the `Zip/Postal Code` field. If the user deletes the information in the `Zip/Postal Code` the `Country` parameter becomes optional.

- `State/Province`

> **Note**
>
> The `State/Province` attribute is configurable only if the `Country` attribute is enabled.

COMPANY INFORMATION

- `Company`
- `Street Address`
- `Street Address 2`
- `City`
- `ZIP/Postal Code`
- `Country`

> **Note**
>
> The `Country` parameter is required when the `Zip/Postal Code` is filled in by the user in the registration form. For example, this is the situation when both `Zip/Postal Code` and `Country` are optional, and the user fills in the `Zip/Postal Code` field. If the user deletes the information in the `Zip/Postal Code` the `Country` parameter becomes optional.

- `State/Province`

> **Note**
>
> The `State/Province` attribute is configurable only if the `Country` attribute is enabled.

- `Industry`

- `Relationship`
- `Job Function`
- `Department`
- `Job Title`

CONTACT PREFERENCES

- `By Email`
- `By Telephone`

> **Note**
>
> The *CONTACT PREFERENCES* attributes define if the self-registration form contains a section *Contact Preferences*. This section asks the user if he or she would like to be contacted by email or phone, or both.
>
> The presence of this section depends also on the `Country` attribute. The legislation in some countries requires the user to explicitly agree that he or she would like to be contacted by email or phone, or both.
>
> Based on the specific configuration, the following options are possible:
>
> - If one or both *CONTACT PREFERENCES* parameters are enabled, and both `Country` parameters are disabled the *Contact Preferences* section will appear in the registration form.
> - If one or both `Country` parameters and one or both *CONTACT PREFERENCES* parameters are enabled, the *Contact Preferences* section will appear in the registration form if the user types at least one country which requires the user to explicitly agree that he or she would like to be contacted by email or phone, or both.
> - If both *CONTACT PREFERENCES* parameters are disabled, the "Contact Preferences" section will not appear in the registration form.
>
> For the full set of the countries that do not require the user to explicitly agree that he or she would like to be contacted by email or phone copy the respective URL listed below, replace `<tenant ID>` with your *Tenant ID*, and open the edited URL in a Web browser.

Contact Preference	Countries

By Email	`https://<tenant ID>.accounts.ondemand.com/md/implicitOptInEmailCountryKeys`
	or
	`https://<tenant ID>.accounts.cloud.sap/md/implicitOptInEmailCountryKeys`

Contact Preference	Countries

By Telephone	`https://<tenant ID>.accounts.ondemand.com/md/implicitOptInTelefonCountryKeys`
	or
	`https://<tenant ID>.accounts.cloud.sap/md/implicitOptInTelefonCountryKeys`

In addition to these profile attributes, the registration and upgrade forms include terms of use and privacy policy documents that are configured separately.

To configure profile attributes, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *Authentication*, choose *User Attributes for Access*.
6. Configure which attributes the form displays as required or optional, and save your selection.

   If the operation is successful, you receive the message `Registration form updated`.
7. **Optional:** To change the phone country selection, choose *Tenant Settings**Tenant Default Values*, select the desired country from the drop-down and save your changes.

   > ⓘ Note
   >
   > The phone country selection appears on the registration and upgrade forms, the verify phone screen, two-factor authentication with SMS screen, and also on the profile page.
   >
   > The default value is United States.

Next Steps

Configure terms of use and privacy policy documents. For more information, see Configuring Privacy Policies [page 2235] and Configuring Terms of Use [page 2273].

Related Information

Create a New Application [page 1922]

1.7.1.21 Protecting Self-Registration, Upgrade with Phone Verification

Tenant administrators can configure applications to require new self-registered users and existing users to verify themselves via SMS codes sent to their mobile phones.

Context

Applications with self-registration process can verify newly created users via a code sent as an SMS to their mobile phones. The applications can therefore protect against users creating numerous dummy accounts.

Newly created users are required to provide their phone numbers during the self-registration process. For more information about how to allow self-registration, see Configure User Access to the Application [page 2025].

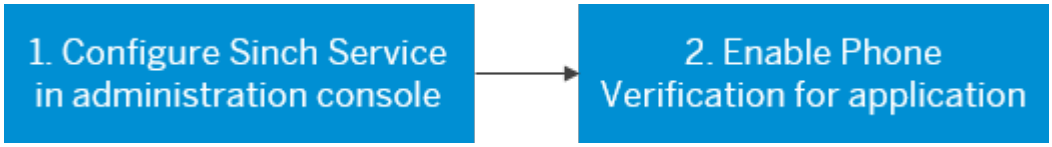
Existing users are required to provide their phone numbers in the upgrade form.

> ✤ Example
>
> Michael Adams is an administrator at retail company A. He has configured his system in such a way that users can register on their own and then purchase from the company's site. He allows users to access his *Company A Purchasing* application by self-registration.
>
> Michael also wants to restrict users to create dummy accounts. To do this, he configures Sinch Service and enables the *Phone Verification via SMS* option in the administration console for SAP Cloud Identity Services.
>
> Donna Moore is a customer who wants to purchase goods from company A for the first time. When she accesses company A's application, she is redirected to the company's logon page. Because she is not registered yet, she has to choose the *Register* button to start the registration process. A registration form then appears, prompting Donna to enter her name, email address, and telephone number, and to accept the organization's terms of use and privacy policy. The telephone number is required when the *Phone Verification via SMS* option is enabled. When she submits the form, she receives an email with instructions

on how to activate her registration. Once she has activated her registration, she receives a code via SMS. At the same time she is redirected to a page where she is prompted to verify her phone number by entering the code she received. Once she has verified the phone number, she is able to log on to the retailing application with her user credentials.

Julie Armstrong is a customer who has an account for company A, but she has never provided her phone number. When she accesses company A's application, she is redirected to the company's logon page. After she provides her credentials, Julie is required to enter her phone number. She receives a code via SMS, and at the same time is redirected to a page where she is prompted to verify the phone by entering the code she received. Once she has verified the phone number, she is able to log on to the retailing application with her user credentials.

Configuration of phone verification in the administration console for SAP Cloud Identity Services comprises two consecutive steps. As a prerequisite, you must have an account in Sinch Service.



- Configure Sinch Service in Administration Console [page 2051]
- Enable Phone Verification for an Application [page 2053]

1. Configure Sinch Service in Administration Console [page 2051]
   Configure Sinch Service to enable *Phone Verification via SMS* or *SMS Two-Factor Authentication* in the administration console.
2. Enable Phone Verification for an Application [page 2053]
   Tenant administrators can enable phone verification via SMS code for an application.

1.7.1.21.1 Configure Sinch Service in Administration Console

Configure Sinch Service to enable *Phone Verification via SMS* or *SMS Two-Factor Authentication* in the administration console.

Prerequisites

- You have an account in Sinch Verification Service. Once you create a Sinch service account, you receive an email with your account information.
- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Sinch service enables multichannel two-factor authentication (2FA), adding another layer of security to customers' online accounts, beyond their login and password. The service enables you to configure tokens – such as one-time passwords (OTPs), personal identification numbers (PINs), and verification codes – that are tailored to businesses and particular use cases.

For the integration between Identity Authentication and Sinch service, you must provide information in the administration console for SAP Cloud Identity Services. You can have a Sinch Verification configuration. You can clear the fields by choosing the *Remove Configuration* button at the top of the screen.

Provide the following:

Sinch Verification

Configuration	Notes
Application Key	The *Application Key* obtained via Sinch customer dashboard.
Application Secret	The *Application Secret* obtained via Sinch customer dashboard.
Code Timeout	Optional. Request the Sinch Support team to configure this parameter for the client's Sinch account. → Remember Before configuring this property in the administration console for SAP Cloud Identity Services, first request this property to the Sinch Support team.
SMS Text Template	Optional. Request the Sinch Support team to enable this configuration. The SMS text in the configuration must include the `{{CODE}}` placeholder, where Sinch will include the actual code. For example, `"This is your OTP code {{CODE}}!"` → Remember Before configuring this property in the administration console for SAP Cloud Identity Services, first request this property to the Sinch Support team.

→ Remember

It takes 2 minutes for the configuration changes to take place.

To configure the administration console, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Sinch Service Configuration* list item.
4. Choose the *Edit* button.
5. Select *Sinch Verification* and enter the information that is required.
6. Save your entries.

Task overview: Protecting Self-Registration, Upgrade with Phone Verification [page 2050]

Next task: Enable Phone Verification for an Application [page 2053]

Related Information

Sinch Verification API

1.7.1.21.2 Enable Phone Verification for an Application

Tenant administrators can enable phone verification via SMS code for an application.

Prerequisites

- You have an account in Sinch Service.
- You have configured Sinch Service. For more information, see Configure Sinch Service in Administration Console [page 2051].

Context

This option requires the user to provide his or her phone number in the registration or upgrade forms. After that the user receives a verification code which must be provided so that the registration or upgrade is completed. If the code fails to arrive, the user has up to five attempts to request a new code via SMS.

After that the user can either contact the system adminstrator or request a code via a phone call. Again the user has up to five attempts to request a new code via phone call. The user can trigger one phone call per session.

When this feature is enabled, the **Phone** attribute becomes required and is not configurable for user registration or upgrade. For more information, see Configure Registration and Upgrade Forms [page 2046].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ### Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *APPLICATION FORMS CUSTOMIZATION*, enable *Phone Verification via SMS*.

   If the operation is successful, you receive the following message: `Application <Application Name> updated`. The slider is switched to *ON*.

   > ### Note
   >
   > If you do not want to use phone verification via SMS for an application, you can drag the slider next to it to *OFF*.

6. **Optional:** Configure rules to skip phone verification for user types and save your changes. To configure the authentication rules, choose one of the following:

Option	Description
Add a new rule	See Add a New Phone Verification Rule [page 2055].
Delete an existing rule	Choose the delete icon next to the rule you want to delete.

   If the operation is successful, the system displays the message `Verification rules updated`.

Results

Newly created users are required to provide their phone numbers during the self-registration process.

Existing users are required to provide their phone numbers in the upgrade form.

Users should enter the code sent by SMS to their phones in order to finish the validation process.

After the phone number is verified, the user can change it on the profile page, after entering a code sent by SMS to their phones.

Task overview: Protecting Self-Registration, Upgrade with Phone Verification [page 2050]

Previous task: Configure Sinch Service in Administration Console [page 2051]

1.7.1.21.2.1 Add a New Phone Verification Rule

You can add rules to skip phone verification for user types.

Context

Each rule contains the following information:

- **Action**
  You can choose the *Skip* action. Users of the selected user type in the rule will not be prompted to verify their phones when the *Phone Verification Via SMS* option is enabled.
- *User Type*
  Specify the type, which the user must have.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the list item of the application that you want to edit.

> ### Note
>
> If you do not have a created application in your list, you can create one. For more details, see Related Information.

> ### Caution
>
> The list also includes the `Administration Console` application. If you enable risk-based authentication for that application, make sure that you, as a tenant administrator, meet the

authentication rules and the default authentication rule. Otherwise when you log out of the administration console you will not be able to log in it again if you don't meet the rules.

If `Administration Console` is not in the list of the applications you may request it. To do this, you need to report an incident with a subject on SAP Support Portal Home under the component `BC-IAM-IDS`.

4. Choose the *Branding and Layout* tab.
5. Under *Application Forms Customization*, choose *Phone Verification Via SMS*.
6. Choose *Add Rule*.
7. Fill in the fields on the *New Verification Rule* window.
8. Confirm your changes.
9. Choose *Save*.

   If the operation is successful, the system displays the message `Verification rules updated`.

Protecting Self-Registration, Upgrade with Phone Verification [page 2050]

1.7.1.22 Protecting Application Forms with Google reCAPTCHA

Tenant administrators can use Google reCAPTCHA to protect the application forms of Identity Authentication against spam and abuse.

> ⓘ Note
>
> The content in this section is not relevant for China (Shanghai) region.

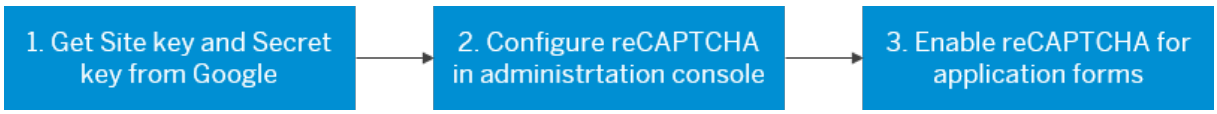
Identity Authentication has integrated Google's Invisible reCAPTCHA service. The aim is to prevent software applications that run automated tasks to flood Identity Authentication.

At present, you can protect the registration form, the login page, and the phone verification pages of Identity Authentication.

> → Remember
>
> To use reCAPTCA:
>
> - for the registration form - you must have allowed self-registration for the application. For more information, see Configure User Access to the Application [page 2025]. Choose *Public* access.
> - for the phone verification pages - you must have enabled phone verification. For more information, see Enable Phone Verification for an Application [page 2053].

reCAPTCHA is provided in the form of a widget that is visible on the protected application form. If the reCAPTCHA service suspects that the user is not a human, a popup with a challenge appears prompting the user to solve a CAPTCHA. By default, only the most suspicious traffic is affected. For more details about Google reCAPTCHA, see **Related Information**.

Configuration of reCAPTCHA for the different application forms of Identity Authentication comprises three consecutive steps:



- Get Site Key and Secret Key from Google for reCAPTCHA [page 2057]
- Configure Google reCAPTCHA in Administration Console [page 2058]
- Enable Google reCAPTCHA for Application Forms [page 2059]

1. Get Site Key and Secret Key from Google for reCAPTCHA [page 2057]
   Register the domain of the application and get a Site key and Secret key from Google.
2. Configure Google reCAPTCHA in Administration Console [page 2058]
   Configure Google reCAPTCHA for your Identity Authentication tenant.
3. Enable Google reCAPTCHA for Application Forms [page 2059]
   Enable Google reCAPTCHA for the registration form, login page, and the phone verification pages of the application.

Related Information

Making the Internet safer and faster: Introducing reCAPTCHA Android API

1.7.1.22.1 Get Site Key and Secret Key from Google for reCAPTCHA

Register the domain of the application and get a Site key and Secret key from Google.

Prerequisites

You have a Google account.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Procedure

1. Log on to your Google account.
2. Access `https://www.google.com/recaptcha/admin` from your browser.
3. Select the *Invisible reCAPTCHA* radio button.
4. Register your domain.

   > **→ Remember**
   >
   > Your domain is the URL of your Identity Authentication tenant. It has the `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap` pattern.
   >
   > *Tenant ID* is automatically generated by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*.

5. Save your Site key and your Secret key. You need them for the configuration steps in the administration console for SAP Cloud Identity Services.

Task overview: Protecting Application Forms with Google reCAPTCHA [page 2056]

Next task: Configure Google reCAPTCHA in Administration Console [page 2058]

1.7.1.22.2 Configure Google reCAPTCHA in Administration Console

Configure Google reCAPTCHA for your Identity Authentication tenant.

Prerequisites

You have registered the domain of the application and received a Site key and Secret key from Google. For more information, see Get Site Key and Secret Key from Google for reCAPTCHA [page 2057].

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *CAPTCHA Service* list item.
4. Choose the *Google reCAPTCHA* service.
5. Enter the **`Site Key`** and **`Secret Key`** you received from Google for reCAPTCHA.
6. Save your changes.

Task overview: Protecting Application Forms with Google reCAPTCHA [page 2056]

Previous task: Get Site Key and Secret Key from Google for reCAPTCHA [page 2057]

Next task: Enable Google reCAPTCHA for Application Forms [page 2059]

1.7.1.22.3 Enable Google reCAPTCHA for Application Forms

Enable Google reCAPTCHA for the registration form, login page, and the phone verification pages of the application.

Prerequisites

- You have registered the domain of the application and received a Site key and Secret key from Google. For more information, see Get Site Key and Secret Key from Google for reCAPTCHA [page 2057].
- You have configured the *Google reCAPTCHA* option in the administration console for SAP Cloud Identity Services. For more information, see Configure Google reCAPTCHA in Administration Console [page 2058].

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Branding and Layout* tab.
5. Under *APPLICATION FORMS CUSTOMIZATION*, choose *CAPTCHA Protection*.
6. Enable the CAPTCHA protection for the relevant application form:
   - *Registration Form*

     > **→ Remember**
     >
     > You must have allowed self-registration for the application. For more information, see Configure User Access to the Application. Choose Public access.
   - *Login Page*
   - *Phone Verification*

     > **→ Remember**
     >
     > You must have enabled phone verification for the application. For more information, see Enable Phone Verification for an Application [page 2053].
7. Save your configuration.

   If the operation is successful, you receive the following message: `Application <Application Name> updated`. The slider next to enabled application form is switched to *ON*.

   > **Note**
   >
   > If you do not want to use CAPTCHA protection for an application form, you can drag the slider next to it to *OFF*.

Task overview: Protecting Application Forms with Google reCAPTCHA [page 2056]

Previous task: Configure Google reCAPTCHA in Administration Console [page 2058]

1.7.1.23 Protecting Application Forms with MTCaptcha

Tenant administrators can use MTCaptcha to protect the application forms of Identity Authentication from spam and abuse.

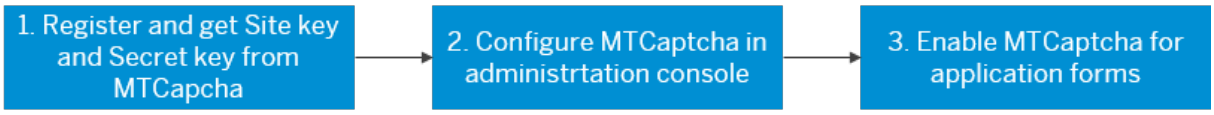
Identity Authentication has integrated the MTCaptcha service. The aim is to prevent software applications that run automated tasks to flood Identity Authentication.

At present, you can protect the registration form, the login page, and the phone verification pages of Identity Authentication.

> → Remember
>
> To use MTCaptcha:
>
> - for the registration form - you must have allowed self-registration for the application. For more information, see Configure User Access to the Application [page 2025]. Choose *Public* access.
> - for the phone verification pages - you must have enabled phone verification. For more information, see Enable Phone Verification for an Application [page 2053].

MTCaptcha is provided in the form of a widget that is visible on the protected application form.

Configuration of MTCaptcha for the different application forms of Identity Authentication comprises three consecutive steps:



- Get Site Key and Private Key for MTCaptcha [page 2062]
- Configure MTCaptcha in Administration Console [page 2062]
- Enable MTCaptcha for Application Forms [page 2063]

1. Get Site Key and Private Key for MTCaptcha [page 2062]
   Register the domain of the application and get a Site key and Private key from MTCaptcha.
2. Configure MTCaptcha in Administration Console [page 2062]
   Configure MTCaptcha for your Identity Authentication tenant.
3. Enable MTCaptcha for Application Forms [page 2063]
   Enable MTCaptcha for the registration form, login page, and the phone verification pages of the application.

1.7.1.23.1 Get Site Key and Private Key for MTCaptcha

Register the domain of the application and get a Site key and Private key from MTCaptcha.

Context

If you have an MTCaptcha registered account and Site Key, skip the procedure below and proceed with Get Site Key and Private Key for MTCaptcha [page 2062].

Procedure

1. Access MTCaptcha website from your browser and sign up..
2. Provide the required information and continue to the next step.

   > → Remember
   >
   > Your domain is the URL of your Identity Authentication tenant. It has the `<tenant ID>.accounts.ondemand.com` pattern.
   >
   > *Tenant ID* is automatically generated by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*.
3. Configure your account.
4. Save your Site key and your Secret key. You need them for the configuration steps in the administration console for SAP Cloud Identity Services.
5. Save your configuration.

Task overview: Protecting Application Forms with MTCaptcha [page 2061]

Next task: Configure MTCaptcha in Administration Console [page 2062]

1.7.1.23.2 Configure MTCaptcha in Administration Console

Configure MTCaptcha for your Identity Authentication tenant.

Prerequisites

You have registered the domain of the application and received a Site key and Private key from MTCaptcha.

Context

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *CAPTCHA Service* list item.
4. Choose the *MTCaptcha* service.
5. Enter the information in the provided fields:
   - **`Site Key`** - enter the Site Key provided from MTCaptcha
   - **`Secret Key`** - enter the Private Key provided from MTCaptcha
6. Save your changes.

Task overview: Protecting Application Forms with MTCaptcha [page 2061]

Previous task: Get Site Key and Private Key for MTCaptcha [page 2062]

Next task: Enable MTCaptcha for Application Forms [page 2063]

1.7.1.23.3 Enable MTCaptcha for Application Forms

Enable MTCaptcha for the registration form, login page, and the phone verification pages of the application.

Prerequisites

- You have registered the domain of the application and received a Site key and Private key from MTCaptcha. For more information, see Get Site Key and Private Key for MTCaptcha [page 2062].
- You have configured the *MTCaptcha* option in the administration console. For more information, see Configure MTCaptcha in Administration Console [page 2062].

Context

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *APPLICATION FORMS CUSTOMIZATION*, choose *CAPTCHA Protection*.
6. Enable the CAPTCHA protection for the relevant application form:

   - *Registration Form*

     > → Remember
     >
     > You must have allowed self-registration for the application. For more information, see Configure User Access to the Application. Choose Public access.

   - *Login Page*
   - *Phone Verification*

     > → Remember
     >
     > You must have enabled phone verification for the application. For more information, see Enable Phone Verification for an Application [page 2053].

7. Save your configuration.

   If the operation is successful, you receive the following message: `Application <Application Name> updated`. The slider next to enabled application form is switched to *ON*.

   > ⓘ Note
   >
   > If you do not want to use CAPTCHA protection for an application form, you can drag the slider next to it to *OFF*.

Task overview: Protecting Application Forms with MTCaptcha [page 2061]

Previous task: Configure MTCaptcha in Administration Console [page 2062]

1.7.1.24 Authenticating Identity Provider for an Application

You can choose an authenticating identity provider for the application.

Context

You have the following options for an authenticating identity provider in the administration console for SAP Cloud Identity Services for both bundled and charged applications, and for system applications (`Administration Console`, and `User Profile`):

- Local Identity Provider
  Identity Authentication is set as the default local identity provider for bundled, charged, and system applications.
  The local identity provider gives you access to all application settings in the administration console for SAP Cloud Identity Services.

  > ⓘ Note
  >
  > When Identity Authentication is set as the default authenticating provider, and the service provider (SP) is configured to send a `login_hint` parameter, the user identifier is prefilled on the login screen.
  >
  > The `login_hint` parameter is sent according to the configuration done on tenant level. For more information, see Configure Login Hint Parameter [page 2604].
  >
  > The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen.

- Corporate Identity Provider
  - Identity Authentication can act as a proxy to delegate authentication to the external corporate identity provider for both bundled and charged applications, and for system applications.

    > ⓘ Note
    >
    > When Identity Authentication is set as proxy, and the service provider (SP) is configured to send a `login_hint` parameter, the `login_hint` coming from the SP will be sent to the corporate IdP in the authentication request.
    >
    > The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen.

    > → Remember
    >
    > If you want to use a corporate identity provider for a system application, the `name ID` attribute sent in the assertion by that corporate identity provider must match the *Email*, *Login Name* or *User ID* attribute of the user in the user store of Identity Authentication.
    >
    > You should also configure the following options for that corporate provider in the administration console for SAP Cloud Identity Services:
    >
    > 1. Enable *Use Identity Authentication user store*.
    > 2. (Optional) Enable *Apply Application Configurations*. This is needed if you want to apply the custom application configurations for authentication and access policies.

> For more information about how to enable these options, see Configure Identity Federation [page 2614]

- Identity Authentication can act also as a proxy to delegate authentication to multiple external corporate identity providers for again both bundled and charged applications, and for system applications. The scenario includes more than one corporate IdP so the tenant administrator must define URLs that lead users to the application and predefine the IdP that should be used. Thus the users don't need to know about the different IdPs and don't need to choose any. For example one corporate IdP is for employees login, and another is for customers. By default, the application redirects to the IdP for clients, while the employees have a crafted link in their corporate portal page, starting the application with login via the IdP for employees. Thus, neither the employees, nor the customers need to do anything to reach the right IdP for them.
  In this case, the administrator has the following options:
  - Configure rules to decide which identity provider to use in which case. For more information, see Configure Conditional Authentication for an Application [page 2076].

    > **Note**
    >
    > This case requires input from the user at sign in.

  - Provide users with URLs that choose the identity provider. For more information, see Create URLs to Access Applications with Specific Identity Providers [page 2605].

Based on your scenario you can:

- Choose Default Identity Provider for an Application [page 2067]
- Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]
- Configure Conditional Authentication for an Application [page 2076]
- Enable SSO with Corporate Identity Providers [page 2087]

Choose Default Identity Provider for an Application [page 2067]
: You choose between a local identity provider and a corporate identity provider to be the default identity provider for your application.

Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]
: You can enable users to log on via Identity Authentication when a corporate identity provider (IdP) is chosen as default.

Configure Conditional Authentication for an Application [page 2076]
: Tenant administrator can define rules for authenticating identity provider according to email domain, user type, user group, and IP range (specified in CIDR notation).

Configure Identity Federation for Applications [page 2084]
: Tenant administrator can enable identity federation for an application to override the identity federation settings on the configured corporate identity provider for the application.

Enable SSO with Corporate Identity Providers [page 2087]
: Tenant administrators can enable IdP-initiated Single Sign-On (SSO) from one, more than one or all configured corporate identity providers (IdPs).

Related Information

Corporate Identity Providers [page 2556]
Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]
Edit Administrator Authorizations [page 2309]

1.7.1.24.1 Choose Default Identity Provider for an Application

You choose between a local identity provider and a corporate identity provider to be the default identity provider for your application.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have a configured corporate identity provider. For more information how to configure a corporate identity provider, see Related Information.
- You haven't added any rules for authentication. For more information, see Configure Conditional Authentication for an Application [page 2076].

Context

In this scenario you choose which is the default identity provider. It can be either the local identity provider (Identity Authentication) or a corporate identity provider.

Initially Identity Authentication is set as the default local identity provider.

This choice gives you access to all application settings in the administration console for SAP Cloud Identity Services.

If the choice is a corporate identity provider, Identity Authentication acts as a proxy to delegate authentication to the external corporate identity provider. For more information, see Corporate Identity Providers [page 2556]

When you select a corporate identity provider, and you want to apply the custom application configurations for authentication and access policies, you should enable *Apply Application Configurations* for that corporate identity provider. For more information, see Configure Identity Federation [page 2614].

To choose a default identity provider for an application, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under the *Conditional Authentication* section, choose the *Conditional Authentication* list item.
6. Select from the drop down the identity provider that the application will use as the default identity provider.
7. Save your changes.

   Once the application has been updated, the system displays the message `Conditional Authentication updated`.

   The application will use only the chosen identity provider for authentication.

   If you select the local identity provider, you will able to access the custom configurations for the applications.

   If you select a corporate identity provider, you will access only some of the custom configurations for the applications. The configurations under the *Authentication and Access* and *Branding and Layout* tabs will be partially visible. The user will be prompted to provide credentials in a single logon page.
8. **Optional:** (When a corporate identity provider is chosen as default identity provider) Enable the *Allow Identity Authentication Users Log On* option. For more information see, (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074].

Task overview: Authenticating Identity Provider for an Application [page 2065]

Related Information

Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]
Configure Conditional Authentication for an Application [page 2076]
Configure Identity Federation for Applications [page 2084]
Enable SSO with Corporate Identity Providers [page 2087]
Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]

1.7.1.24.2 Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default

You can enable users to log on via Identity Authentication when a corporate identity provider (IdP) is chosen as default.

Sometimes you have multiple identity providers in your landscape, whether they are corporate identity providers or your SAP Cloud Identity Services - Identity Authentication tenant. By providing your users with preconfigured URLs, you can direct them to authenticate with specific identity providers for specific applications.

How you prepare these URLs depends on whether the user starts at the identity provider or at the application. It's further modified by your use case. Some typical use cases are described as follows.

Opting for the Local Identity Provider

You can enable users that are stored in SAP Cloud Identity Services to log on with their Identity Authentication credentials. Thus, the employees log on to the application with their corporate credentials, while the external users, such as clients, partners, or SAP support users are authenticated by the local Identity Authentication tenant. Another example is if you're developing an application and you want to use a test user in the local identity provider instead of creating a test user in the corporate identity provider. The following figure illustrates this architecture.

Sign On With the Local Identity Provider and not the Corporate Identity Provider

Example

Example approuter link:

```
https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
sap_idp=custom.sap
```

Note that the approuter needs the origin key for the custom identity provider for the SAP BTP account.

Example link:

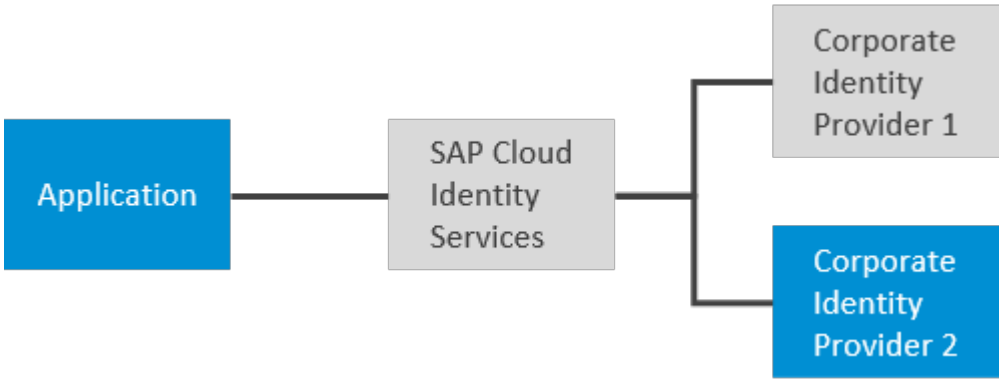
```
https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
my_sci_tenant.accounts.ondemand.com
```

Example with local value:

```
https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=local
```

Multiple Corporate Identity Providers

If your application doesn't define rules to determine which identity provider a user authenticates with, SAP Cloud Identity Services offers the choice to your users. To avoid users choosing the wrong identity provider, you can limit their choices. The following figure illustrates this architecture.

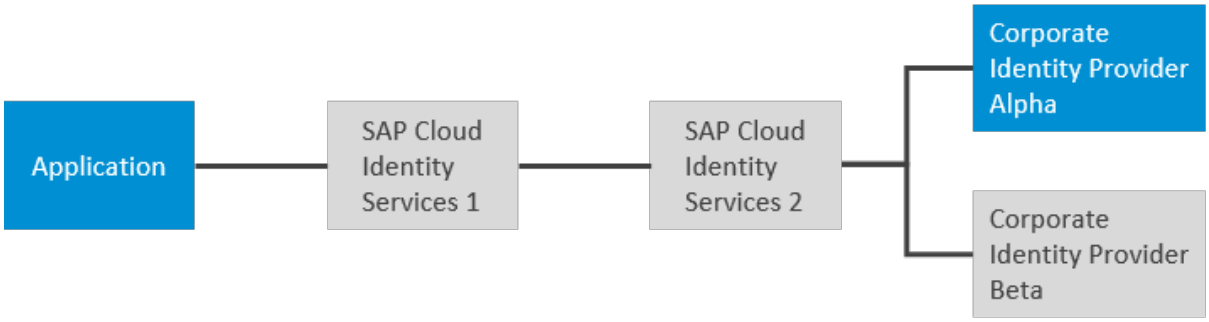


Help Direct Users to the Correct Identity Provider

> ### Example
>
> Example approuter link:
>
> ```
> https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
> sap_idp=https://corp_idp_2.mydomain.com
> ```
>
> Example link:
>
> ```
> https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
> corp_idp_2.mydomain.com
> ```

Deep Hierarchy of Identity Providers

Your landscape has multiple levels of identity providers, perhaps through subsidiaries and conglomerate organizations. You want to direct your users to a specific identity provider, but this identity provider isn't directly known by your SAP Cloud Identity Services tenant. In such cases, provide the chain of identity providers to which the user must be redirected to reach the authenticating identity provider. The following figure illustrates this architecture.



Deep Structure of Identity Providers

> ### Example
>
> Example approuter link:
>
> ```
> https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
> sap_idp=https://scis_2.mydomain.com,corp_idp_alpha.mydomain.com
> ```
>
> Example link:
>
> ```
> https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
> scis_2.mydomain.com,corp_idp_alpha.mydomain.com
> ```

Identity-Provider-Initiated Single Sign-On

> ### Restriction
>
> This option is only supported by SAML.

Identity-provider-initiated single sign-on (IdP-initiated SSO) is used for central portals in an enterprise from which users access applications. Users log on to the central portal first. You need to identify the identity provider the user must log on with. You also need to identify the service provider that the user is forwarded to after authenticating. The identity provider can be SAP Cloud Identity Services or a corporate identity provider or a hierarchy of corporate identity providers. Another unique aspect of IdP-initiated SSO is that the URL pattern you use is determined by SAP Cloud Identity Services. Otherwise, the URL is defined by the application. The following figure illustrates this architecture.

Identity-Provider-Initiated Single Sign-On

> **Example**
>
> Example SAML URL:
>
> ```
> https://my_sci_tenant.accounts.ondemand.com/saml2/idp/sso?sp=https://
> myapplication.cfapps.eu20-001.hana.ondemand.com&idp=https://
> corp_idp_1.mydomain.com
> ```

1. Choose a Corporate Identity Provider as Default [page 2072]
   You choose a corporate identity provider to be the default identity provider for your application.
2. (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074]
   Users can log on with their Identity Authentication credentials, when a corporate identity provider is selected as default.
3. Creating URLs for Applications to Authenticate with Specific Identity Providers [page 2075]
   The URL to access an application is generally determined by the application. When you have multiple identity providers available, you can steer users to the correct identity provider with the `idp` parameter.

Parent topic: Authenticating Identity Provider for an Application [page 2065]

Related Information

Choose Default Identity Provider for an Application [page 2067]

Corporate User Store (Neo Environment) [page 2531]

1.7.1.24.2.1 Choose a Corporate Identity Provider as Default

You choose a corporate identity provider to be the default identity provider for your application.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have a configured corporate identity provider. For more information how to configure a corporate identity provider, see Corporate Identity Providers [page 2556].

Context

To choose a corporate identity provider as default, follow the procedures:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under the *Conditional Authentication* section, choose the *Conditional Authentication* list item.
6. Select from the drop down the corporate identity provider that the application will use as the default identity provider.
7. Save your changes.

   Once the application has been updated, the system displays the message `Conditional Authentication updated`.

Results

When the choice is a corporate identity provider, you are not able to access the custom configurations for the applications. The *Authentication and Access* and *Branding and Layout* tabs are not visible.

Task overview: Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]

Next task: (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074]

1.7.1.24.2.2 (Optional) Use the Allow Identity Authentication Users Log On Option

Users can log on with their Identity Authentication credentials, when a corporate identity provider is selected as default.

Prerequisites

You have chosen a corporate identity provider as default. For more information, see Choose a Corporate Identity Provider as Default [page 2072].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.
4. Choose the *Trust* tab.
5. Under *Conditional Authentication*, select the *Allow users stored in Identity Authentication service to log on* check box.

   > **Note**
   >
   > By default this option is disabled.
   >
   > The check box is visible only if you have chosen a corporate identity provider as default.

6. Save your selection.

Task overview: Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]

Previous task: Choose a Corporate Identity Provider as Default [page 2072]

Next task: Creating URLs for Applications to Authenticate with Specific Identity Providers [page 2075]

1.7.1.24.2.3 Creating URLs for Applications to Authenticate with Specific Identity Providers

The URL to access an application is generally determined by the application. When you have multiple identity providers available, you can steer users to the correct identity provider with the `idp` parameter.

Prerequisites

- You have set a corporate IdP as the default identity provider in the administration console.
  For more information, see Choose a Corporate Identity Provider as Default [page 2072].
- The application supports selection of the corporate IdP with the idp parameter in the application URL. See the documentation of the application.

  > **Example**
  >
  > Example: Many BTP applications use the application router, which requires the `sap_idp` query parameter.
  >
  > For more information, see @sap/approuter at *npm*.

- If you have enabled the *Allow Identity Authentication Users Log On* option, you can use the reserved name **`local`** to authenticate with your Identity Authentication tenant.
  For more information, see (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074].

Procedure

Use the `idp` parameter in the URL for OIDC or in the URL or body for SAML.

> **Caution**
>
> It depends on the service provider whether the parameter can be passed in body or URL. Identity Authentication doesn't control how the SAML 2.0 request is sent.

Parameters

Parameter	Description
`idp`	Name of the identity provider as defined under the *Name* in the *Trust* configuration of the identity provider. • For SAML, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]. • For OIDC, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579]. If you need a chain of identity providers, use a comma without spaces (,) to separate them. Use the value **`local`** to override the conditional authentication configuration and authenticate with Identity Authentication instead.

Task overview: Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]

Previous task: (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074]

1.7.1.24.3 Configure Conditional Authentication for an Application

Tenant administrator can define rules for authenticating identity provider according to email domain, user type, user group, and IP range (specified in CIDR notation).

Prerequisites

You are assigned the *Manage Applications* and *Manage Groups* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Tenant administrator can control the access to an application by defining different rules for the authenticating identity provider. Based on these rules users are authenticated either via a corporate identity provider or via Identity Authentication.

Rules

The added rules are displayed sorted by priority.

If a rule contains only *IP Range*, and it is first in list or only one, Identity Authentication does not request the user to provide user identifier in the logon screen. The system evaluates whether that user meets all the criteria of the rule. The evaluation starts with the rule with the highest priority, until the criteria of a rule are met. If the criteria of a rule are met, the rest of the conditions are not evaluated

If apart from *IP Range* the rule contains other conditions, or it is not the first in the list, Identity Authentication requests the user to provide user identifier in the logon screen. When a user types the user identifier in the log on page, the system evaluates whether that user meets all the criteria of the rule. The evaluation starts with the rule with the highest priority, until the criteria of a rule are met. If the criteria of a rule are met, the rest of the conditions are not evaluated.

> → Remember
>
> Rules can be defined only if the default identity provider is Identity Authentication.
>
> If you have already defined rules, they won't be considered if you change the default identity provider from Identity Authentication to a corporate identity provider.
>
> To use two or more corporate identity providers and not the default Identity Authentication, your rules must cover all cases so that no user ends up at Identity Authentication. Once you make your other rules, create a catch-all rule with the IP range `0.0.0.0/0`. Such a rule set at the lowest priority ensures that no users end up at Identity Authentication as the default identity provider.

> ⓘ Note
>
> If the user is already existing in Identity Authentication, authentication requests via SPNEGO, existing session, remember me, and token will be processed by Identity Authentication in case of successful authentication no matter of the conditional authentication rules. However, when the tenant has trusted certificate configuration, the application is SAML 2.0 type, and a conditional rule is configured, authentication is done by the local identity provider (IdP) with the certificate, except for the scenario when the conditional rule has an IP Range defined. In this case, if the rule matches, the user will be sent for authentication to the IdP from the rule.

Default Identity Provider

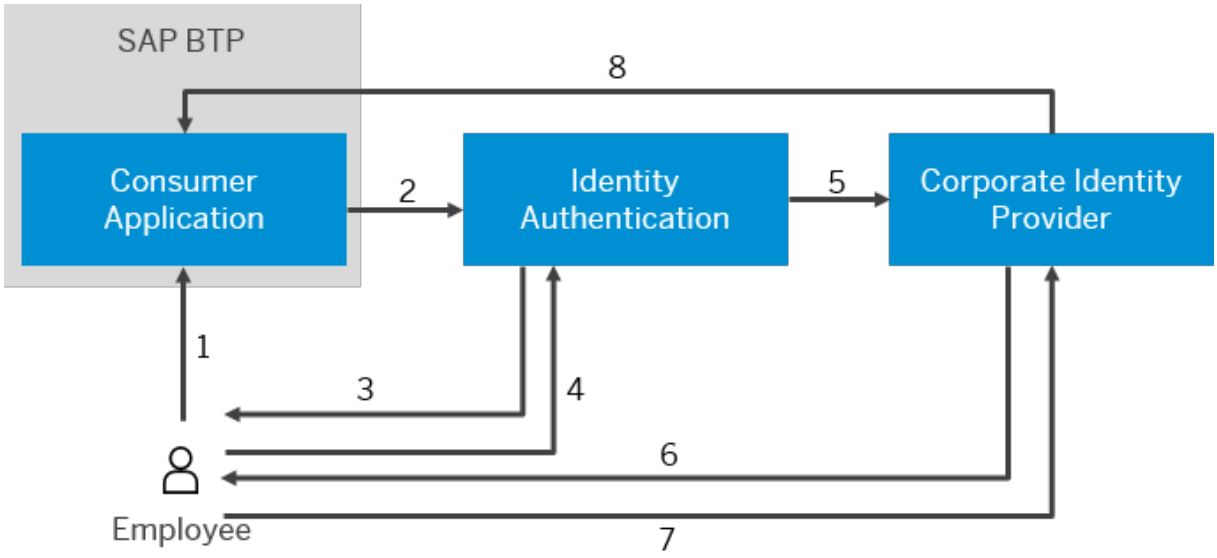
If non-prompt based authentication (SPNEGO, existing session, remember me, and token) is successful, the user is authenticated without checking the rules via Identity Authentication. Otherwise, the user will be asked to provide identifier to evaluate the conditional authentication rules.

If none of the rules meets the criteria, Identity Authentication is chosen for authentication.

Conditional Authentication Flow

The tenant administrator has configured Conditional Authentication in the administration console for SAP Cloud Identity Services. In this setup, the employee should be authenticated via the corporate identity provider, while the customers via Identity Authentication.

Authentication via Corporate Identity Provider



1. The user tries to access the application.
2. The application redirects the request to Identity Authentication to check the rules.
3. Identity Authentication requests the user to provide user identifier in the logon screen.

   > → Remember
   >
   > If the rule contains only *IP Range* Identity Authentication does not request the user to provide user identifier in the logon screen. This step is skipped for this scenario.
   >
   > If apart from *IP Range* the rule contains other conditions, this step is executed.

4. The user provides user identifier. Identity Authentication stores the user identifier in a persistent cookie in the browser. The persistent cookie expires in 36 months.

   > → Remember
   >
   > If the rule contains only *IP Range* Identity Authentication does not request the user to provide user identifier in the logon screen. This step is skipped for this scenario.
   >
   > If apart from *IP Range* the rule contains other conditions, this step is executed.

5. According to the rules, the user should be authenticated via the corporate identity provider. Identity Authentication sends the user identifier as `login_hint` parameter to the corporate identity provider in the authentication request, according to the *Login Hint Configuration* configuration in the administration console.

   > ⓘ Note
   >
   > The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen.

   > → Remember
   >
   > The user identifier from step 3 is required at the first logon. After that, based on the persistent cookie, the user is redirected directly to the logon screen of the corporate identity provider.
   >
   > If the user wants to log on with another identifier, he or she must delete the browser cookies.

> When the persistent cookie expires, the user is again requested to provide user identifier in the logon screen.

6. If the corporate identity provider supports the `login_hint` parameter, then it requests only the user password. If the corporate identity provider does not support the `login_hint` parameter, it requires both the user identifier and password.
7. Depending on the support of the `login_hint`, user provides only password, or both user identifier and password.

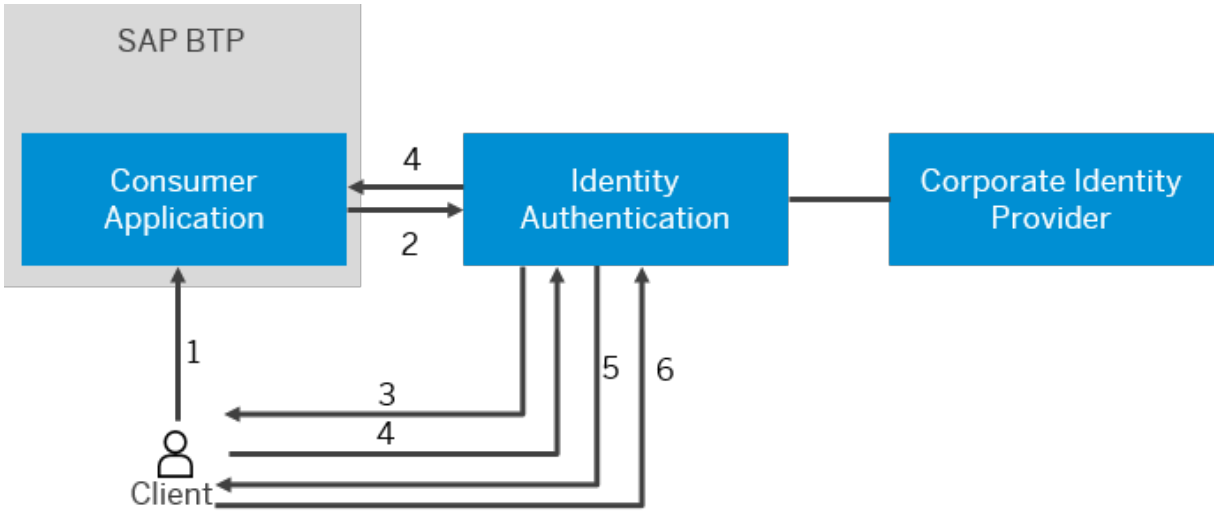
> ### Note
>
> The user can change the prefilled value. The new value is sent to the corporate IdP. If there is an existing conditional authentication cookie, the user identifier stored in that cookie is prefilled on the conditional screen and the `login_hint` is not taken into account.

8. The corporate identity provider grants access to the user.

Result

The user logs on to the application.

Authentication via Identity Authentication



1. The user tries to access the application.
2. The application redirects the request to Identity Authentication to check the rules.
3. Identity Authentication request the user to provide user identifier in the log on screen.

> ### → Remember
>
> If the rule contains only *IP Range* Identity Authentication does not request the user to provide user identifier in the logon screen. This step is skipped for this scenario.
>
> If apart from *IP Range* the rule contains other conditions, this step is executed.

4. The user provides user identifier.

> → Remember
>
> If the rule contains only *IP Range* Identity Authentication does not request the user to provide user identifier in the logon screen. This step is skipped for this scenario.
>
> If apart from *IP Range* the rule contains other conditions, this step is executed.

5. According to the rules, the user should be authenticated via Identity Authentication. The user is prompted to provide password. The user identifier is prefilled in the logon screen.
6. User provides password.
7. Identity Authentication grants access to the user.

Result

The user logs on to the application

> ⓘ Note
>
> Social sign-on and account linking is supported only when the user does not meet the configured rules for conditional authentication.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Conditional Authentication*, choose *Conditional Authentication*.
6. Configure the rules. To configure the rules, choose one of the following options:

Option	Description
Add a new rule	See Add a New Authentication Rule [page 2082].
Edit an existing rule	Choose the icon next to the rule you want to edit.
Delete an existing rule	Choose the delete icon next to the rule you want to delete.

Option	Description
Reprioritize rules	Use the arrows to reprioritize the rules.

7. Choose the default identity provider.

> ⚠ Restriction
>
> Rules can be defined only if the default identity provider is Identity Authentication.

8. Save your changes.

   Once the application has been updated, the system displays the message `Conditional Authentication updated`.

Example: Setting Conditional Authentication

Donna Moore is an administrator of Company A. She wants to configure Identity Authentication so that the employees who log on with their corporate emails to be authenticated via the company's corporate identity provider. The clients and partners of Company A should be authenticated via Identity Authentication. For this purpose, Donna creates the following authentication rule:

Authentication Rule

Identity Provider	Email Domain	User Type	User Groups
Company A Corporate IdP	companya.com		

Default Identity Provider: Identity Authentication

Michael Adams is an employee of Company A and as such he wants to create a leave request. He chooses the logon link on the application and is prompted to provide his email. After that he chooses *Continue* and is redirected to the logon screen of Company A. There he has to provide his user identifier and password. After providing the correct credentials he logs on to the application.

Julie Armstrong is a customer of Company A. She accesses the company's application and chooses the logon link on the application and is prompted to provide her email. After that she chooses *Continue* and is redirected to the log on screen of Identity Authentication where she is prompted to provide her password. Her email is prefilled by the system. After providing the correct password she logs on to the application.

1.7.1.24.3.1 Add a New Authentication Rule

You can add rules for authentication against different identity providers.

Prerequisites

You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Each rule contains the following information:

- *Identity Provider*
  Define the identity provider that will be used for authentication.
  The dropdown list includes the local identity provider and all corporate identity providers that are created in the administration console for SAP Cloud Identity Services. The corporate identity providers must be configured in the administration. For more information, see Corporate Identity Providers [page 2556].

  > → Remember
  >
  > This field is required.

- *Email Domain*
  Specify the domain of the email address that comes after the @ symbol. You can use asterisk (`*`) in the domain part, for example: `*.example.com`.
  If no domain is entered, the rule is valid for any domain.
- *User Group*

  > ⚠ Restriction
  >
  > The administrator must be assigned the *Manage Groups* role or be part of a policy that allows reading groups to be able to view the groups in the list. For more information, see Edit Administrator Authorizations [page 2309] or Configure Group Authorizations [page 2320].

  Specify the group, which the authenticating user must be part of. If no group is selected, the rule is valid for any of the groups.
  The user groups must be configured in the administration console for SAP Cloud Identity Services. For more information, see Managing Groups [page 2393].

  > ⓘ Note
  >
  > The authenticating user must exist in the user store of Identity Authentication for the *User Group* criteria to be checked properly.

- *User Type*
  Specify the type, which the authenticating user must have. If no user type is selected, the rule is valid for any of the types.

  > **Note**
  >
  > The authenticating user must exist in the user store of Identity Authentication for the *Type* criteria to be checked properly.

- *IP Range*
  Define the range of allowed IP addresses or proxies that the user logs on from. The value must be specified in Classless Inter-Domain Routing (CIDR) notation.

  > **Note**
  >
  > By default the field is empty, meaning that any IP is allowed.

  > **Example**
  >
  > Enter 123.45.67.1/24 to allow users to log on from any IP starting with 123.45.67.

  If no IP range is defined, the rule is valid for all IP ranges.

> **→ Remember**
>
> The fields *Domain*, *Group*, *User Type*, and *IP Range* are not mandatory, but at least one of them has to be specified.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Conditional Authentication*, choose *Conditional Authenticating Identity Providers*.
6. Choose *Add New Rule*.
7. Fill in the fields on the *New Rule* window.
8. Confirm your changes.

Related Information

Create a New Application [page 1922]

1.7.1.24.4 Configure Identity Federation for Applications

Tenant administrator can enable identity federation for an application to override the identity federation settings on the configured corporate identity provider for the application.

Prerequisites

- You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured Identity Authentication to use a corporate identity provider as an external authenticating authority. For more information, see Create Corporate IdP in Administration Console [page 2558].
- You have selected a configured identity provider as the authenticating identity provider for your application. For more information, see Choose Default Identity Provider for an Application [page 2067].

Context

The *Identity Federation* option allows you to choose whether the user attributes are taken from the corporate IdP assertion or from Identity Authentication user store. Additionally, you can also apply the custom application configurations for the authentication and access policies, as well as allow access based on user groups and email domains.

In scenarios where the application is using a corporate identity provider with *Identity Federation* settings for authentication, the administrator can configure identity federation for the application and override this configuration. This provides a more fine-grained identity federation in situations where multiple applications use the same corporate IdP as an external authenticating authority.

User Store

> → Remember
>
> By default, the *Identity Federation* for an application option is disabled. Enabling the configuration will override the *Identity Federation* settings of the authenticating identity provider.

When *Use Identity Authentication user store* option is enabled, the application checks if the users authenticated by the corporate identity provider exist in the Identity Authentication user store. The existence check is done with the name identifier sent by the corporate identity provider for the identifying attributes `uid`, `loginName`, `emails` and `phoneNumber`.

For users that exist in Identity Authentication, data from Identity Authentication user store is taken and the subject name identifier, assertion and default attributes according to the application configuration are sent. For users with no profile in Identity Authentication, the application receives the nameID attribute from the corporate IdP assertion, and the attributes according to the application configuration.

User Access

By default, *Allow Identity Authentication users only* is disabled, and all users successfully authenticated to the corporate IdP are allowed.

When *Allow Identity Authentication users only* is enabled, only the users that exist in Identity Authentication can access the application.

Restrict Logon to Members of Certain Groups from the Corporate Identity Provider

As a next step, you can assign a group or groups to the corporate IdP. Only users from the Identity Authentication user store that are members of the assigned group can access the application.

> → Remember
>
> You can assign groups, only when *Allow Identity Authentication users only* option is enabled. If disabled, the assigned groups option is not taken into consideration. As a next step, you can assign a group or groups to the corporate IdP or allow certain email domains.

Restrict Logon to Members of Certain Groups

You can assign a group or groups to the corporate identity provider. Only users from the Identity Authentication user store that are members of the assigned groups can access the application.

> → Remember
>
> You can assign groups, only when *Allow Identity Authentication users only* option is enabled. If disabled, the assigned groups option is not taken into consideration.

Restrict Logon to Users with Certain Email Domains

You can add email domains to restrict the access to those specific email domains. Only users from the Identity Authentication user store whose email domains are allowed can access the application.

> → Remember
>
> You can allow email domains from the allow list, only when the *Allow Identity Authentication users only* option is enabled. If disabled, the allow list option is not taken into consideration.

Application Configuration

Additionally, the *Apply Application Configurations* option can be enabled. By default, this option is disabled.

When enabled, the user is authenticated by the corporate IdP, then *Identity Authentication* checks for the configurations for authentication and access policies on application level, and applies them. They include *Risk-Based-Authentication*, *Terms of Use*, *Privacy Policy*, *Upgrade and Registration Forms*.

> → Remember
>
> The concurrent user access configuration is always applied for the application regardless of the *Apply Application Configurations* state.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Select the application that you want to configure for *Identity Federation*.

> **Note**
>
> Type the name of the application in the search field to filter the list items, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose *Identity Federation* to configure the options.
5. Choose *Edit* > *Custom*.
6. Select the desired check boxes:

Option	Description
Use Identity Authentication user store	When you select it, the *Allow Identity Authentication users only* becomes available for selection.
Allow Identity Authentication users only	When you select it, the *Apply Application Configurations* becomes available for selection. Additionally, the *User Groups* and *Allowed Email Domains* sections become visible. There you can see a list of the groups assigned to this corporate IdP and the allow list for email domains. If no groups are assigned or no email domain added, the lists are empty. • To restrict logon to members of certain groups, choose the *Add* button. Select the groups that you want to assign to this corporate identity provider. The list does not include the groups that are already assigned to the corporate identity provider. **Note** To remove groups, choose *Edit*, select the groups you want to remove, choose the *Remove* button, and save your changes. Users that belong only to the unassigned groups will not be able to access the application any more. • To restrict logon to users from certain email domains, under *Email Domains*, choose the *Add* button. Type the email domains that you want to add to the allow list. **Note** To remove email domains, choose *Edit*, select the email domains you want to remove, choose the *Remove* button, and save your changes. Users whose emails contain only the removed email domains will not be able to access the application any more.
Apply Application Configuration	

7. Save your changes.

Task overview: Authenticating Identity Provider for an Application [page 2065]

Related Information

Choose Default Identity Provider for an Application [page 2067]

Configure Conditional Authentication for an Application [page 2076]
Enable SSO with Corporate Identity Providers [page 2087]

1.7.1.24.5 Enable SSO with Corporate Identity Providers

Tenant administrators can enable IdP-initiated Single Sign-On (SSO) from one, more than one or all configured corporate identity providers (IdPs).

Prerequisites

- You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have more than one corporate identity provider, which is configured in the administration console. For more information on how to configure a corporate identity provider, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560] or Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
- (For SAML 2.0 applications) You have added the assertion consumer (ACS) endpoint with the URL of the application's protected page, and the index, in the metadata of that application. The ACS endpoint that you added should look like the following example:

  Sample Code

  ```
  <ns3:AssertionConsumerService index="1" isDefault="false"
  Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://
  <application URL>/protected.jsp"
  />
  ```

  For more information how to configure your ACS endpoint in the administration for Identity Authentication, see Configure SAML 2.0 Service Provider [page 1941].

Context

Applications can be configured to trust one, more than one, or all corporate identity providers configured in the administration console when identity provider (IdP) initiated Single Sign-On (SSO) is used. The user accesses the application via a URL provided by the corporate identity provider.

To enable IdP-initiated SSO with corporate identity providers configured in the administration console for SAP Cloud Identity Services follow the following procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ### Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under the *Conditional Authentication* section, choose the *Trust Corporate Identity Providers* list item.
6. | Option | Notes |
   | --- | --- |
   | **Enable the slider to allow SSO with all configured corporate identity providers.** | All corporate IdPs are allowed for sign-in.

By default this option is disabled. If enabled, all configured corporate IdPs are hidden, and you can't select a specific IdP from the list. |
   | **Select a specific corporate IdP from the list.** | → Remember

The slider on the top-right corner of the screen must be disabled. If enabled, all configured corporate IdPs are hidden |

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Results

The application trusts the selected corporate identity providers that are configured in the administration console for SAP Cloud Identity Services.

Task overview: Authenticating Identity Provider for an Application [page 2065]

Related Information

Choose Default Identity Provider for an Application [page 2067]
Configure Logon via Identity Authentication when a Corporate IdP is Chosen as Default [page 2069]
Configure Conditional Authentication for an Application [page 2076]
Configure Identity Federation for Applications [page 2084]
Configure IdP-Initiated SSO with Corporate Identity Providers [page 2564]

1.7.1.25 Use IdP-Initiated Single Logout (SLO)

Use this procedure to start the single logout (SLO) process at Identity Authentication as an identity provider.

Context

Single Logout (SLO) enables users to cleanly close all their sessions in an SSO landscape, even across domains. In this identity provider (IdP) initiated SLO scenario, the user initiates a logout request at Identity Authentication being an identity provider.

SLO can also be initiated at the corporate identity provider (IdP). Identity Authentication accepts SLO requests from corporate identity providers via both SAML and OpenID Connect.

Procedure

1. Direct the user browser to your SLO endpoint.

   Identity Authentication single logout endpoint follows the template `https://<tenant ID>.accounts.ondemand.com/saml2/idp/slo` or `https://<tenant ID>.accounts.cloud.sap/saml2/idp/slo`
2. **Optional:** Add the `RelayState` parameter to provide a relative URL to which the identity provider redirects after the SLO process is complete.

   > → Remember
   >
   > The `RelayState` must be a trusted domain and valid URL. For example, `https://myapplication.ondemand.com/saml2/idp/slo?RelayState=https://example.com`

Results

After successful logout, the identity provider either redirects the user to the URL provided in the RelayState, or if RelayState isn't provided, the user is redirected to the profile page.

Related Information

Configure Trusted Domains [page 2173]

1.7.1.26 Integrating Applications

Enable applications to call each other's APIs, consume reuse services, share authorization context, or hand off authenticated sessions by configuring dependencies in SAP Cloud Identity Services.

SAP Cloud Identity Services supports four types of dependencies. Each type serves a distinct integration scenario as determined by the developer of the application:

Dependency Type	Use When
Provided APIs [page 2090]	One application calls the APIs of another application. The consumer uses technical communication or principal propagation.
Configure Service Dependencies [page 2095]	An application consumes a reuse service, such as the Destination service or Job Scheduling service, using its own token.
Configure Shared Authorization Dependencies [page 2096]	A consumer application, such as a portal or shell, needs to know what a user is authorized to do in a provider application without calling that application directly. The provider's authorization groups are projected as claims into the consumer's token.
Configure Native-Web Trust Dependencies [page 2099]	A native or mobile application hands off an authenticated session to a web application without requiring the user to log in again.

1.7.1.26.1 Provided APIs

Applications sometimes need to propagate principals or have technical communication arrangements between them. To enable one application to consume the APIs of another application, the developer of the application providing APIs defines one or more API permission groups, which the consuming application can consume.

Under this model, applications that can be called by other applications define API permission groups. Administrators grant access to these groups to consuming applications. These permission groups cover a set of related APIs. An application can expose all its APIs without an API permission group when there is no need to restrict consuming applications.

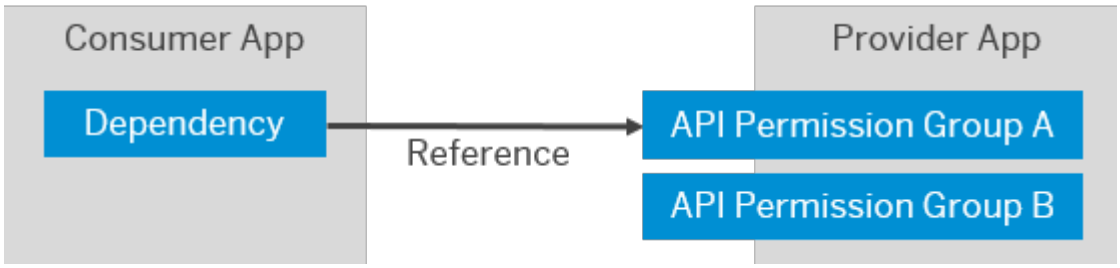
You can set up technical communication or principal propagation.

- With technical communication, you can map authorizations to the communication.
- With principal propagation, user authorizations apply in the decision whether an API call is allowed or not.

In the configuration of the consumer application, the tenant administrator defines the dependencies. Consumer applications use the dependency name to identify to SAP Cloud Identity Services which application the consumer wants to access, including the API permission group to grant.

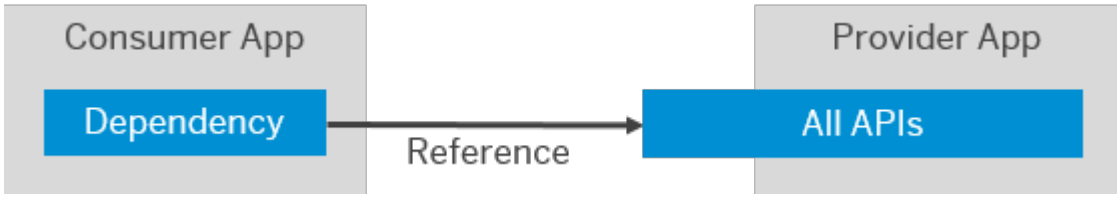
- Typically, an application needs a specific name for integration with a specific provider application. Find the supported dependency names in the provider application or its documentation.
- When an application generically integrates with many arbitrary applications, the application rather enables you to define custom dependency names and maintain them both in SAP Cloud Identity Services as well as in the consuming application itself. The configuration informs the application which dependency to use for which integration scenario.

The following figure shows the relationship between two applications in SAP Cloud Identity Services. The provider application offers two API permission groups. The consumer app is allowed to consume one of these groups. The applications can use technical communication or principal propagation.



App-to-App Integration of API Permission Groups

In the following figure, the provider application doesn't offer any API permission groups. The consumer application references all the available APIs. The provider application depends on the authorizations of the current user when these APIs are accessed.



App-to-App Integration of All APIs

- To configure dependencies, see Configure Integration Between Applications [page 2092].
- To consume APIs from an application that is not registered in SAP Cloud Identity Services, see Generate Credentials to Access the APIs of an Application [page 2093].
- For more information about developing such applications, see Consuming APIs from Other Applications [page 2889].

Configuration Precedence

When you configure both the consumer and provider applications, each application contributes specific OIDC and related configurations. The following table shows which application provides each configuration.

Configuration Source by Application

Configuration	Application	More Information
Subject name identifier	Provider	Configure the Subject Name Identifier Sent to the Application [page 1988]
Token attributes	Provider	User Attributes [page 1972]
Token format	Provider	Token Policy Configuration for Applications [page 2752]
Token grant type	Consumer	Token Policy Configuration for Applications [page 2752]
Token policy	Consumer	Token Policy Configuration for Applications [page 2752]

1.7.1.26.1.1 Configure Integration Between Applications

Define a dependency to the API of another application. With this configuration, you authorize one application to consume the API of another application.

Prerequisites

- You know the name of the provider application and API permission group needed by the consumer application.
  The provider application defines the name of the API permission group during deployment, in the documentation of the application, or from the developers directly for custom developments.
  If the provider application offers all APIs, then you don't need to know the name of a specific API permission group.
  For more information, see Provide APIs for Consumption by Other Applications [page 2891].
- You know the name of the dependency to enter for the consumer application.
  The consumer application must define this name automatically during deployment, in the documentation of the application, or from the developers directly for custom developments.
  For more information, see Integrating Applications [page 2090].

Procedure

1. In the administration console for SAP Cloud Identity Services, choose *Applications and Resources* > *Applications*.
2. Choose the consumer application.
3. Choose the *Trust* tab.

4. Under *Application APIs*, choose *Dependencies*.
5. Enter the required data.

   You can create a maximum of 400 dependencies.

   a. Enter a unique name for the dependency.
   b. Choose the provider application and the API that the consumer application consumes.
6. Save your entries.

Results

The consumer application can consume the specified API of the provider application.

Next Steps

If the applications were developed with a generic implementation, you must configure the consumer application with the dependency name you provided. See the documentation of the consumer application.

For more information about how application developers use this dependency, see Consume an API from a Provider Application [page 2893].

1.7.1.26.1.2 Generate Credentials to Access the APIs of an Application

When integrating applications, create API credentials for the consumer application. From your *Provided APIs*, create a dependent application or create a dependency with an existing application.

Prerequisites

You have created at least one API permission group.

For more information, see Provide APIs for Consumption by Other Applications [page 2891].

Context

The main use cases for this method are as follows:

- You want to integrate an application, which otherwise isn't aware of SAP Cloud Identity Services, such as a non-SAP application. The application requires OAuth credentials, which you provide with this procedure. These credentials enable you to integrate this non-SAP application with the provider application.

- As a developer of a provider application, you want to test your APIs, but don't have a consumer application to integrate with.

Procedure

1. In the administration console for SAP Cloud Identity Services, choose *Applications and Resources* > *Applications*
2. Choose the provider application.
3. Choose the *Trust* tab.
4. Under *Application APIs*, choose *Provided APIs*.
5. Under *Dependent Applications*, choose *Create*.

> ⓘ Note
>
> If you haven't configured an API permission group, the *Dependent Applications* section doesn't appear.

6. Enter the required data.
   a. Enter a unique name for the dependency.
   b. Select the API that the consumer application consumes.
   c. Decide whether you want to create a new application or use an existing one.
      - Create a new application, to create a consumer you can use to test your provided API with. Enable *Generate Secret* to generate client credentials for the new application.
      - Use an existing application to integrate an existing consumer with your provider.
7. Choose *Create*.

> → Remember
>
> If you chose to create a new application and a secret, a dialog summarizes the new dependency. Copy the *Client ID* and *Client Secret* to a safe location. Also copy the *Resource*. You provide this information to the consumer application so it can get a token for the provider application.
>
> For example, using the client credentials flow for a technical communication arrangement, the consumer application can call the `/token` endpoint of Identity Authentication. The service returns a token that the application uses to call the APIs of the provider application. The following is a cURL example of such a call.
>
> ```
> curl  $iashost/oauth2/token -X POST \
>    -H 'Content-Type: application/x-www-form-urlencoded' \
>    -H 'Accept: application/json' \
>    -d "client_id=3ab1ba0e-c573-4ad5-20a4-28aa4e587a19" \
>    -d "client_secret=$secret" \
>    --data-urlencode 'grant_type=client_credentials' \
>    --data-urlencode
> 'resource=urn:sap:identity:application:provider:name:techDependency'
> ```
>
> For more information, see Consume an API from a Provider Application [page 2893].
>
> You can navigate directly to the new application configuration from the dialog.

1.7.1.26.2 Configure Service Dependencies

Enable an application to consume a reuse service using its own token by adding the service to the `consumed-services` property in the Identity service instance parameters.

Prerequisites

- For Cloud Foundry, the reuse service instance exists in the same space as your application.
  For more information, see Creating Service Instances in the SAP BTP documentation.
- You know the name of the service instance of the reuse service.

Context

Use service dependencies when your application needs to call a platform reuse service, such as the Destination service or the Job Scheduling service, using its own application token. The developer of your application must design the application to use mutual TLS when calling the reuse service. The reuse service validates the audience claim of that token to confirm the caller is authorized.

You can reference only reuse services that are designed and documented to support the `consumed-services` parameter. SAP BTP platform services such as the Destination service and Job Scheduling service support this pattern.

> **Note**
>
> You configure service dependencies in the Identity service instance parameters at deployment time. The resulting dependency is visible in the administration console under the application's *Dependencies* > *Services* tab, but you can't modify it there.

Procedure

1. In the Identity service instance parameters of your application, configure the `consumed-services` property.

   In the `consumed-services` array, list each reuse service by its service instance name:

```
{
…
  "consumed-services": [
    {
      "service-instance-name": "<name-of-reuse-service-instance>"
    }
  ],
…
}
```

You can list up to 400 services.

> **Note**
>
> If the token is retrieved based on a public client flow (`public-client` is `true`) without client authentication, SAP Cloud Identity Services doesn't add the client IDs of the dependent services to the audience claim.

2. Create or update the Identity service instance, referencing this parameter file.

   The Identity service instance creation validates that each entry in `consumed-services`refers to an existing, SAP Cloud Identity Services-based service instance. If validation fails, the instance creation fails with an error identifying the unresolvable entry.

Results

SAP Cloud Identity Services adds the client IDs of the named reuse services to the audience (`aud`) claim of tokens issued for this application. Your application can then obtain a token and present it when calling the reuse service with mTLS. The reuse service validates the `aud` claim to confirm the caller is a trusted consumer.

Related Information

Reference Information for the Identity Service of SAP BTP [page 2921]

1.7.1.26.3 Configure Shared Authorization Dependencies

Enable a consumer application to receive authorization group information from a provider application as claims in its access token. With this configuration, the access token of the consumer application includes the authorization groups that the authenticated user holds in the provider application.

Prerequisites

- The provider application has application-specific groups of type authorization.
- You know the display name or application ID of the provider application in your SAP Cloud Identity Services tenant.
- The token claim has been configured by mapping the `dependencyGroups` user attribute to a claim name required by the consumer application.
  To check look for `<consumer-claim-name>` mapped to a self-defined attribute in the application configuration of the consumer application. For more information about self-defined attributes, see User Attributes [page 1972].

If there is no mapping or you haven't deployed the application yet, use one of the following methods:

- When the provider application was deployed, an entry was added to the `assertion-attributes` property in the Identity service instance parameters for the provider application.

  ```
  {
    "assertion-attributes": {
      "<consumer-claim-name>": "dependencyGroups"
    }
  }
  ```

  For more information, refer to the documentation of the consumer and provider applications.

- Send a PATCH request to the Applications REST API of your SAP Cloud Identity Services tenant:

  ```
  PATCH ${iasUrl}/Applications/v1/${consumerAppId}
  Content-Type: application/json
  {
    "operations": [
      {
        "op": "add",
        "path":
  "/urn:sap:identity:application:schemas:extension:sci:1.0:Authentication/
  assertionAttributes",
        "value": [
          {
            "assertionAttributeName": "<consumer-claim-name>",
            "userAttributeName": "dependencyGroups"
          }
        ]
      }
    ]
  }
  ```

  > ⚠ Caution
  >
  > If you set assertion-attributes through the Identity service instance parameters or use the `replace` operation when using the REST API, your map fully replaces the default set of five user profile claims (`groups`, `given_name`, `family_name`, `email`, `user_uuid`). To keep these claims, restate them alongside your new entry.

> → Tip
>
> Replace `<consumer-claim-name>` with the claim name that the consumer application reads from the token, for example, **`dependency_groups`**.
>
> For more information, refer to the documentation of the consumer and provider applications.

Context

Use shared authorization dependencies when a consumer application (such as a portal, shell, or assistant) needs to know what a user is authorized to do in a provider application, without calling that application directly. The provider application's application-specific groups for that user are included as a claim in the consumer's access token. The consumer application reads this claim and uses it to tailor its behavior, for example, to show or hide tiles or features.

The dependency is one-directional: only the consumer's tokens carry the claim. No configuration is required on the provider application. You can add up to 20 shared authorization dependencies per consumer application.

The claim appears only in access tokens, not in ID tokens.

Procedure

1. Add the shared authorization dependency in the administration console.
   a. In the administration console for SAP Cloud Identity Services, choose *Applications and Resources* > *Applications*.
   b. Choose the consumer application.
   c. Choose the *Trust* tab.
   d. Under *Application APIs*, choose *Dependencies*.
   e. Choose *Shared Authorizations*.
   f. Choose *Add* and select the provider application.
   g. Save your entries.
2. Assign the application-specific groups of the provider application to the users who require authorizations.

   To determine which groups to assign, refer to the documentation of the consumer and provider applications.

   For more information about application-specific groups, see Groups [page 514].

Results

When an authenticated user obtains an access token for the consumer application, the token includes a claim named `<consumer-claim-name>` that contains a map of the authorization groups that the user holds in the configured provider applications.

Related Information

Groups [page 514]
Claims of SAP Cloud Identity Services OAuth Tokens [page 2744]

1.7.1.26.4 Configure Native-Web Trust Dependencies

Enable a native or mobile application to hand off an authenticated session to a web application without requiring the user to log in again.

Prerequisites

- The native application has the token exchange grant type enabled (`urn:ietf:params:oauth:grant-type:token-exchange`).
- The native application has an active refresh token for the authenticated user.
- You know the name of the target web application in your SAP Cloud Identity Services tenant.

Context

Use native-web trust dependencies when a user is already authenticated in a native or mobile application and needs to open a web application in a browser. Without this configuration, the browser has no active session and prompts the user to log in again. With this configuration, the native application exchanges its refresh token for a short-lived, one-time SSO token. This SSO token is then passed to the `/saml2/idp/sso` endpoint of the SAP Cloud Identity Services tenant, which establishes a web session for the user and redirects the browser to the target application without a login prompt.

An application can have up to 20 native-web trust dependencies.

Procedure

1. In the administration console for SAP Cloud Identity Services, choose *Applications and Resources* > *Applications*.
2. Choose the native application (the originating application running on the device).
3. Choose the *Trust* tab.
4. Under *Application APIs*, choose *Dependencies*.
5. Choose *Native-Web Trust*.
6. Choose *Add* and select the target web application.
7. Save your entries.

Results

The native-web trust dependency is established. When the native application performs a token exchange with `resource=urn:sap:identity:sso`, the issued SSO token includes the application ID of the configured

target web application in its `sso_application_ids` claim and the trusted redirect URIs of that application in its `sso_redirect_uris` claim. The user can move from the native application to the web application in a browser without being prompted to log in.

Next Steps

After the SSO flow completes, the user is redirected to a trusted URI. For OIDC applications, the configured redirect URIs are used. For SAML applications, the SSO endpoints are used. For both application types, the home URL is also included. To add a specific post-SSO redirect destination, configure the home URL of the target application.

> ⓘ Note
>
> The web session is always established with the `/saml2/idp/sso` endpoint, regardless of whether the target application uses SAML or OIDC.

1.7.2 Configuring Tenant Settings

Initially, the tenants are configured to use default settings. This section describes how you as a tenant administrator can make custom tenant configurations.

Prerequisites

To see and configure the tenant the options in the *Tenant Settings* tile, you must be assigned the Manage Tenant Configuration role. For more information, see Edit Administrator Authorizations [page 2309].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

Tenant SAML 2.0 Configurations [page 2103]
: You as a tenant administrator can view and download the tenant SAML 2.0 metadata. You can also change the name format and update your certificate used by the identity provider to digitally sign the messages for the applications.

Get SAML 2.0 IdP Metadata via Parameter [page 2107]
: Tenant administrator can get the SAML 2.0 metadata via specific parameters.

Rotate Signing Certificates for Applications [page 2109]
: Tenant administrators must replace existing signing certificates with new ones before they expire.

Tenant OpenID Connect (OIDC) Configurations [page 2117]
: You as a tenant administrator can view and configure the tenant OpenID Connect (OIDC) configurations.

Change Tenant Texts Via Administration Console [page 2121]

The change tenant texts option can be used to change the predefined texts and messages for end-user screens available per tenant in Identity Authentication via the administration console.

Configure Master Data Texts Via Administration Console [page 2125]
The master data texts option can be used to configure the predefined master data for each resource in Identity Authentication via the administration console.

Configure Links Section on Sign-In Screen [page 2129]
You can configure links to appear on the sign-in screen of your applications.

Add Instructions Section on Sign-In Screen [page 2133]
You can customize the sign-in screen of the *Horizon* theme with instructions for the user.

Configure X.509 Client Certificates for User Authentication [page 2136]
Tenant administrators can configure X.509 client certificates for user authentication as an alternative to authenticating with a user name and a password.

Enable Users to Generate and Authenticate with Certificates [page 2140]
Allow users to generate and authenticate with certificates.

Configure Tenant Images [page 2142]
You can configure a custom global logo and, or a background image on the forms for sign-in in, registration, upgrade, password update, and account activation for all applications in a tenant. You can also set a favicon for tenant.

Configure Allowed Logon Identifiers [page 2146]
Tenant administrators can choose the allowed logon identifiers for the users.

Configure User Identifier Attributes [page 2149]
Tenant administrators can configure user identifier attributes as required and unique for the tenant.

Configure Trust this browser Option [page 2154]
Tenant administrator can set the number of days for which the users won't get prompted for second-factor authentication, if they sign in from the same browser.

Enable Back-Up Channels to Send Passcode for Deactivation of TOTP Two-Factor Authentication Devices [page 2156]
Tenant administrator can configure back-up channels to send TOTP deactivation passcodes to the user.

Password Recovery Options [page 2158]
Enable users to reset their password via security questions, PIN code, or email link.

Configure Initial Password and Email Link Validity [page 2168]
As a tenant administrator, you can configure the validity of the initial password and link sent to a user in the various application processes.

Configure Session Timeout [page 2170]
As a tenant administrator, you can configure when the session, created at the Identity Authentication tenant, expires.

Configure Trusted Domains [page 2173]
Service providers that delegate authentication to Identity Authentication can protect their applications when using embedded frames, also called overlays, or when allowing user self-registration.

Use Custom Domain in Identity Authentication [page 2175]
Identity Authentication allows you to use a custom domain that is different from the default ones (`<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`) - for example `www.mytenant.com`.

Change a Tenant's Display Name [page 2181]
You can configure the tenant's name from the administration console for SAP Cloud Identity Services.

Configure Default Risk-Based Authentication for All Applications in the Tenant [page 2183]
You can define rules for authentication according to different risk factors and apply actions like *Allow*, *Deny*, and *Two-Factor Authentication* for all applications in a tenant.

Configure Sinch Service in Administration Console [page 2189]
Configure Sinch Service to enable *Phone Verification via SMS* or *SMS Two-Factor Authentication* in the administration console.

Configure RADIUS Server Settings (Beta) [page 2192]
Configure Remote Authentication Dial-In User Service (RADIUS) server settings in the administration console for SAP Cloud Identity Services.

Configure Mail Server for Application Processes [page 2195]
Configure mail server for the emails sent to the end users in the different application processes.

Configure IdP-Initiated SSO [page 2201]
Enable or disable IdP-Initiated SSO via the administration console for SAP Cloud Identity Services.

Sync SSO Cookie Between Domains [page 2207]
Enable the *Sync SSO Cookie Between Domains Settings* option to allow seamless single sign-on (SSO) and single logout (SLO) across the Cloud Identity Services domains - `ondemand.com` and `cloud.sap`.

Send Security Alert Emails [page 2209]
Send security alert emails to end-users or administrators when changes in their accounts are made.

Enable Password Expiration Reminder [page 2211]
Enable password expiration reminder for SAP Cloud Identity Services to ensure the users are aware that a password change is due.

Send System Notifications via Emails [page 2213]
You can configure the administration console to send emails with information about expiring certificates, system notifications, new administrators, and new applications to specific email addresses or to the emails of all administrators.

Configure Default Language for End User Screens [page 2216]
Select the language that the end user screen uses if the language of the browser isn't in the list of supported languages.

Prompt Users to Explicitly Accept Privacy Policy Document [page 2218]
Enable the privacy policy configuration in SAP Cloud Identity Services to prompt users to accept the privacy policy document. This ensures that users explicitly confirm their understanding of document.

Configure P-User Next Index [page 2220]
Set the value for the P-user next index.

Reuse SAP Cloud Identity Services Tenants for Different Customer IDs [page 2222]
You as a tenant administrator can reuse an existing tenant for configurations and automated subscriptions.

1.7.2.1 Tenant SAML 2.0 Configurations

You as a tenant administrator can view and download the tenant SAML 2.0 metadata. You can also change the name format and update your certificate used by the identity provider to digitally sign the messages for the applications.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

> **Note**
>
> For tenants created before 10 September 2024, the signing certificate is one and the same for SAML 2.0 and OpenId Connect (OIDC). Changing one of the configurations causes the service to separate the configuration into two signing certificates, one for SAML and one for OIDC.

→ Remember

The signature and digest methods in the XML of the metadata file depend on the signing certificate, which is configured for the identity provider.

→ Remember

It takes 2 minutes for the configuration changes to take place.

To view and download the tenant SAML 2.0 metadata, or to change the name format, or the default certificate, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Single Sign-On*, choose the *SAML 2.0 Configuration* list item.
   The *SAML 2.0 Configuration* page that opens displays the name of the identity provider, its endpoints, and its signing certificate.
4. **Optional:** To download the identity provider's metadata, press the *Download Metadata File* button and choose one of the options.
   - *Default-certificate*
   - *Non-default certificate*
   - *All certificates*
5. **Optional:** To change the name of the identity provider, choose under the *Identity Provider Settings* tab the *Edit* button next to the *Name* field, select the name from the dropdown list, and save your changes.

   The drop-down list offers the following options:

Issuer	Notes
Default Issuer format	https://<tenant ID>.accounts.ondemand.com
Legacy Issuer format	<tenant ID>.accounts.ondemand.com
Common domain	https://<tenant ID>.accounts.cloud.sap
Custom Domain (if configured)	<custom domain host>
Tenants in China region	https:// <tenant ID>.accounts.sapcloud.cn

> **Note**
>
> Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the tenant ID.

> **→ Remember**
>
> Change the name of the identity provider on the service provider side, or the name of the identity provider on the corporate identity provider side, every time you change the name format of the identity provider in the administration console. If you have set trusts with more than one service provider, or corporate identity provider, change the name in every provider. For more information about how to edit the name, see the documentation of the respective service or corporate identity providers.

If the change of the name is successful, the system displays the message `Tenant <name of tenant> updated`.

6. **Optional:** To update your signing certificate, choose under the *Signing Certificates* tab the *+Add* button on the right. You can choose from the following options:

   - *Regenerate the existing certificate with new validity, reusing the same private key* > *Next Step* > *Choose validity from the drop down* > *Next Step* > *Finish*.

     > **Note**
     >
     > The validity period can be 1, 3, 6 months, 1, 3, 5 and 10 years.

   - *Create new a self-signed certificate with a new private key and the same Subject DN* > *Next Step* > *Select key size* > *Choose validity from the drop down* > *Next Step* > *Finish*.

     > **Note**
     >
     > The key size can be 2048, 3072 and 4096. The validity period can be 1, 3, 6 months, 1, 3, 5, or 10 years.

   - *Download your Certificate Signing Request* > *Next Step* > *add Subject DN and select key size and validity from the options* > *Next Step* > *Download CSR*. Use the downloaded .csr file to generate a certificate from the trusted CA. Copy the newly generated certificate, choose *Edit Certificate*, and paste the certificate as text in the *Certificate Information* field.

     > **Note**
     >
     > The signing algorithm can be SHA-256 and SHA-384. The key size can be 2048, 3072 and 4096.

Next Steps

To change the default certificate for the tenant, choose *Edit* > *the new certificate from the list* > *Save*.

> ⚠ Caution
>
> When you change the default certificate for the tenant, you must also update the trust with the service provider. For more information, see Configure SAML 2.0 Service Provider [page 1941].

1.7.2.2 Get SAML 2.0 IdP Metadata via Parameter

Tenant administrator can get the SAML 2.0 metadata via specific parameters.

Prerequisites

The information in this document is valid only for SAML 2.0 applications.

Context

You can get the SAML 2.0 tenant metadata containing the identity provider (IdP) certificate by calling the `https://<tenant ID>.<tenant domain>/saml2/metadata` end point and providing one of the following parameters:

Parameters

Parameter	Value
`sp_name`	The value is the name of the application as it appears in the *Name* field in the *SAML 2.0 Configuration* screen in the administration console. **Note** If you had added a second signing certificate in the administration console tenant settings for a specific service provider (SP), and you chose one of the certificates to be used for that SP, you can retrieve the SAML 2.0 of the Identity Provider (IdP) metadata for that SP, containing the chosen IDP certificate by providing the SP name in the `sp-name` parameter.

Parameter	Value
`certificates`	• `all` - gets both signing certificates configured for the tenant → Remember If you get the metadata with both certificates to update the trust on the identity provider side, information for the second certificate will be used only. • `default` - gets only the default signing certificate configured for the tenant • `non-default` - gets only the non-default signing certificate configured for the tenant

> ⓘ Note
>
> *Tenant ID* is an automatically generated ID by the system.
>
> The domain can be `accounts.ondemand.com` or `accounts.cloud.sap`

> Example
>
> - `https://mytenant.accounts.ondemand.com/saml2/metadata?sp_name=myapplication` or `https://mytenant.accounts.sap.cloud/saml2/metadata?sp_name=myapplication`
> - `https://mytenant.accounts.ondemand.com/saml2/metadata?certificates=all` or `https://mytenant.accounts.sap.cloud/saml2/metadata?certificates=all`

1.7.2.3.1 Rotate Signing Certificates for SAML 2.0 Applications

Tenant administrators must replace existing signing certificates with new ones before they expire. This ensures uninterrupted and secure communication between SAML 2.0 applications (referred to as service providers) and Identity Authentication as the identity provider.

Context

You have received an email notification that your signing certificate is about to expire. The email is sent 30 days, 14 days, and 3 days before the certificate expires. You need to create a new one and configure the service provider to use it. Proceed as follows:

Procedure

1. Create a new signing certificate.
    1. Sign in to the administration console for SAP Cloud Identity Services.
    2. Navigate to *Applications and Resources* > *Tenant Settings* > *Single Sign-On* > *SAML 2.0 Configuration* > *Signing Certificates*.
2. Choose the *+Add* button on the right. You can choose from the following options:
    - *Regenerate the existing certificate with new validity, reusing the same private key* > *Next Step* > *Choose validity from the drop down* > *Next Step* > *Finish*.

      > ⓘ Note
      >
      > The validity period can be 1, 3, 6 months, 1, 3, 5, or 10 years.

    - *Create new a self-signed certificate with a new private key and the same Subject DN* > *Next Step* > *Select key size* > *Choose validity from the drop down* > *Next Step* > *Finish*.

      > ⓘ Note
      >
      > The key size can be 2048, 3072 and 4096. The validity period can be 3, 5 and 10 years.

    - *Download your Certificate Signing Request* > *Next Step* > *add Subject DN and select key size and validity from the options* > *Next Step* > *Download CSR*. Use the downloaded .csr file to generate a certificate from the trusted CA. Copy the newly generated certificate, choose *Edit Certificate*, and paste the certificate as text in the *Certificate Information* field.

      > ⓘ Note
      >
      > The signing algorithm can be SHA-256 and SHA-384. The key size can be 2048, 3072 and 4096.

3. Configure the service provider to use the new certificate.

> **Note**
>
> In case there are many applications, the recommended approach is to renew the certificate for one application at a time following this procedure, as this will minimize or reduce the potential for customer downtime.

1. Navigate to *Applications and Resources* > *Applications* and select the application for which you want to update the trust configuration.
2. Under *Trust* > *Single Sign-On* > *SAML 2.0 Configuration* > *Identity Provider Certificate* > *disable the slider* > *choose Activate next to the new certificate*.

4. Upload the new certificate to the backend of the trusted application.
   1. Navigate to *Applications and Resources* > *Tenant Settings* > *Single Sign-On* > *SAML 2.0 Configuration*.
   2. Proceed according to your use case below.

Applications	Procedure
Your applications support metadata	1. Download the metadata with this certificate in one of the following ways: • Get the SAML 2.0 tenant metadata containing the identity provider certificate by calling the `https://<tenant ID>.<tenant domain>/saml2/metadata` endpoint and provide the `sp_name` parameter, as described in Get SAML 2.0 IdP Metadata via Parameter [page 2107]. • Download the metadata with the new certificate (which is still a non-default one), as described in Tenant SAML 2.0 Configurations [page 2103] → *Step 4* 2. Upload this metadata to the backend of the application for which you have updated the trust configuration in step 2.
Your applications support certificate file	1. Under *Signing Certificates*, choose the *Download* icon next to the new certificate. 2. Upload this certificate file to the backend of the application for which you have updated the trust configuration in step 2.
Your applications support certificate as text	1. Under *Signing Certificates*, choose the *Display* icon next to the new certificate. 2. Copy and paste the certificate to the backend of the application for which you have updated the trust configuration in step 2.

5. After updating the trust configuration for each application, set the new certificate as the default.

Under *Tenant Settings* > *Single Sign-On* > *SAML 2.0 Configuration* > *Signing Certificates*, select the new certificate as default and save your configuration.

6. Navigate to *Applications and Resources* > *Applications* > *Trust* > *Single Sign-On* > *SAML 2.0 Configuration* > *Identity Provider Certificate* > *enable the slider*.

> **Note**
>
> It takes approximately 2 minutes for the new certificate to appear under the trust configuration of the given application.

1.7.2.3.2 Rotate Signing Certificates for OpenID Connect Applications

Components of SAP Cloud Identity Services use the digital signature of access tokens to verify their validity. Rotate the signing certificates of access tokens periodically to ensure uninterrupted and secure communication between OpenID Connect (OIDC) applications (referred to as relying parties) and Identity Authentication as the identity provider.

Prerequisites

Plan for waiting time in hours between the steps of this procedure.

After you activate a new certificate, wait for access tokens signed by the old certificate to expire before deleting the old certificate. The default lifetime of access tokens is 60 minutes.

For more information, see Token Policy Configuration for Applications [page 2752].

Context

Signing certificates exist at the tenant level and are shared by all applications by default. You can also configure application-specific signing certificates. Shared certificates are easier to consume. However, if you need to rotate certificates, you can't delete the old certificate until **all** applications sharing that certificate are configured to use the new certificate.

For more information, see Configure OpenID Connect (OIDC) Application [page 1949].

SAP Cloud Identity Services sends an email notification when your signing certificate is about to expire. The system sends the email 30 days, 14 days, and 3 days before the certificate expires. Create a new certificate and configure the relying party to use it.

> **Note**
>
> It takes approximately two minutes for the new certificate to appear under the trust configuration of the given application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Navigate to *Applications and Resources* > *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.
3. Check that there's space for a new signing certificate.

   You can store five signing certificates.

   Delete an inactive certificate if you already have five.

   > ⚠ Caution
   >
   > Wait for any existing tokens signed by the inactive signing certificate to expire.
   >
   > By default, access tokens expire after 60 minutes and refresh tokens expire after 12 hours.
   >
   > As long as the old signing certificate exists, the system accepts digital signatures signed by that certificate. After all access tokens and refresh tokens signed by the old certificate expire, you can delete the old certificate. Access tokens have a maximum lifetime of 12 hours. Refresh tokens have a maximum lifetime of 6 months.

4. Add a new signing certificate.

   Choose the *Add* button on the right. You can choose from the following options:

Option	Description
Regenerate	1. Regenerate the existing certificate with new validity, reusing the same private key. 2. Use the wizard to set the validity period and choose *Finish*. → Recommendation Choose a validity period of 3 years.
Create new	1. Create a new self-signed certificate with a new private key and the same Subject Distinguished Name (Subject DN). 2. Use the wizard to set the validity period and key size. Choose *Finish*. → Recommendation Choose a validity period of 3 years. Choose a key size of at least 3072.
Download CSR	1. Download your Certificate Signing Request (CSR). 2. Use the wizard to set the Subject Distinguished Name (Subject DN), signing algorithm, and key size.

Option	Description
	→ Recommendation Choose a key size of at least 3072. 3. Choose *Download CSR*. 4. Use the downloaded `.csr` file to generate a certificate from the trusted CA. 5. Copy the newly generated certificate, choose *Edit Certificate*, and paste the certificate as text in the *Certificate Information* field.

5. Configure your applications that use tenant-level certificates to use the new certificate.

> ⓘ Note
>
> Configuring applications one at a time reduces the potential for downtime.

1. Under *Applications and Resources*, choose the *Applications* tile.
2. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

3. Under *Trust* > *Single Sign-On* > *OpenID Connect Configuration* > *Identity Provider Certificates*, select the new certificate in the *Active* column.

6. Upload the new certificate to the backend of the trusted application.

Proceed according to your use case:

Application Backend Supports	Procedure
The discovery endpoint	Refresh or point your application backend to the discovery endpoint: `https://<Cloud Identity Services domain>/.well-known/openid-configuration`
Certificate files	1. Navigate to *Applications and Resources* > *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration*. 2. Under *Signing Certificates*, choose the *Download* icon next to the new certificate.

Application Backend Supports	Procedure
	3. Upload this certificate file to the backend of the application for which you updated the trust configuration in step 5.
Certificates as text	1. Navigate to *Applications and Resources* > *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration*. 2. Under *Signing Certificates*, choose the *Display* icon next to the new certificate. 3. Copy and paste the certificate to the backend of the application for which you updated the trust configuration in step 5.

7. After you update the trust configuration for each application that uses tenant-level certificates, set the new certificate as the default.

   Under *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*, select the new certificate as the default and save your configuration.

   Any new applications use the new signing certificate by default.
8. Wait for any existing tokens signed by the old signing certificate to expire.

   By default, access tokens expire after 60 minutes and refresh tokens expire after 12 hours.

   As long as the old signing certificate exists, the system accepts digital signatures signed by that certificate. After all access tokens and refresh tokens signed by the old certificate expire, you can delete the old certificate. Access tokens have a maximum lifetime of 12 hours. Refresh tokens have a maximum lifetime of 6 months.
9. Deactivate the old certificate.

   Under *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*, choose ⊗ *Deactivate Certificate*.

   The system no longer accepts tokens signed by this certificate. However, the certificate is not deleted. If some applications stop working because of the deactivated certificate, you can reactivate it.
10. Delete the old signing certificate.

    Under *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*, choose 🗑 *Delete*.

1.7.2.4 Tenant OpenID Connect (OIDC) Configurations

You as a tenant administrator can view and configure the tenant OpenID Connect (OIDC) configurations.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

You can change the name format, the certificate used by the identity provider to digitally sign the messages for the applications, set the token policy by configuring the validity of the refresh token, access and id_token, and the maximum sessions per user, and extend the standard metadata with custom values.

> ⓘ Note
>
> For tenants created before 10 September 2024, the signing certificate is one and the same for SAML 2.0 and OpenId Connect (OIDC). Changing one of the configurations causes the service to separate the configuration into two signing certificates, one for SAML and one for OpenID Connect (OIDC).

The *OpenID Connect (OIDC) Configuration* view in the administration console also shows information about the URLs of the *Domain for Browser Flows*, *Authorization Endpoint*, *Token Endpoint*, *UserInfo Endpoint*, and *Logout Endpoint*.

The token policy for the tenant is defined by configuring the validity of the refresh token, access and id_token, and the maximum sessions per user. It's valid for all the applications in the tenant.

> → Remember
>
> If you want a specific token policy per application, you must set a custom token policy for each application. If you modify the settings on the tenant level, all applications without their own custom token policy are affected. For more information, see Token Policy Configuration for Applications [page 2752]

The following table lists the token policy options for OpenID Connect (OIDC) applications.

Token Policy Configuration Parameters

Parameter	Description

Refresh Token	Sets the refresh token lifetime issued by Identity Authentication. The value can range from 1 to 4320 hours, in other words, from 1 hour to 180 days.
	
	The default value is 12 hours.
	
	Note
	• If the validity of refresh tokens is less than the validity of access/ID tokens, access/ID tokens can't be refreshed after the access/ID tokens expire.
	• When using the authorization code flow, if you set the token policy for refresh tokens longer than the session timeout, add the *offline_access* scope to your authorization code request. Without this scope, the service deletes the refresh token from the database when the resource owner ends the session (logs out). Without the refresh token, the OAuth client can't request new tokens anymore. For more information, see:
	  • Configure Session Timeout [page 2170]
	  • Using Authorization Code Flow [page 2638]

Access / ID Token	Sets the access and id_token lifetime issued by Identity Authentication. The value can range from 1 to 720 minutes, in other words, from 1 minute to 12 hours. The default value is 60 minutes.
Max sessions per user	Determines the maximum number of tokens that the service issues for the same session in parallel. Imagine you're logged on to the application through a web interface and a command-line interface in parallel. Then you'd set this parameter to 2. The value can range from 1 to 10. The default value is 1.

The maximum wait time for front-channel logout can be set between 1 and 10 seconds. The default value is 3 seconds.

→ Remember

It takes 2 minutes for the configuration changes to take place.

To view or change the tenant OpenID Connect (OIDC) configurations, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Single Sign-On*, choose the *OpenID Connect (OIDC) Configuration* list item.
   The *OpenID Connect (OIDC) Configuration* page that opens displays the issuer of the identity provider, its endpoints derived from issuer and domain configurations, signing certificate and token policy.

   > ### Note
   >
   > By default, applications use the domain from their trust configuration to access all the endpoints. For browser-based logons and logouts, you can choose another domain. Applications use the chosen domain after reloading the OpenID Connect (OIDC) metadata.
4. **Optional:** To define the token policy, use the slider or provide a number in the input field above the slider. If needed, use the reset button to set to the default value.
5. **Optional:** To change the issuer of the identity provider, choose the *URL* field, select from the dropdown list, and save your changes.

   > ### Caution
   >
   > OpenID Connect (OIDC) applications use the issuer to identify this tenant. Changing the issuer might cause logon issues for existing applications.

   > ### → Remember
   >
   > Change the issuer of the identity provider on the relying party, or the issuer of the identity provider on the corporate identity provider side, every time you change the *URL* format of the issuer in the administration console. If you have set trusts with more than one relying party, or corporate identity provider, change the issuer in every provider. For more information about how to edit the issuer, see the documentation of the respective relying party or corporate identity provider.
6. **Optional:** Update your signing certificate. You can choose from the following options:

   - To regenerate the existing certificate with new validity, reusing the same private key, choose *Add* > *Regenerate* > *Next Step* > *choose validity from the drop down* > *Next Step* > *Finish* > *Save*.
   - To create a new certificate with a new private key and the same Subject DN, choose *Add* > *Create new* > *Next Step* > *choose key size, signing algorithm, and validity from the drop downs* > *Next Step* > *Finish* > *Save*.
   - To create a new certificate, using your own trusted CA, choose *Add* > *Download CSR* > *Next Step* > *add Subject DN, signing algorithm, and key size from the drop downs* > *Next Step* > *Download CSR*. Use the .csr file to generate a certificate from the trusted CA. Copy the newly generated certificate, choose *Edit Certificate*, and paste the certificate as text in the *Certificate Information* field.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113] and Generate Elliptic Curve Signing Certificates [page 2593].

7. **Optional:** Set the maximum wait time for front-channel logout.

Next Steps

To change the default certificate for the tenant, choose the new one from the list, and save your configuration.

> ⚠ Caution
>
> When you change the default certificate for the tenant, you must also update the trust with the service provider. For more information, see Configure OpenID Connect (OIDC) Application [page 1949] or Configure OpenID Connect (OIDC) Application [page 1949].

1.7.2.5 Change Tenant Texts Via Administration Console

The change tenant texts option can be used to change the predefined texts and messages for end-user screens available per tenant in Identity Authentication via the administration console.

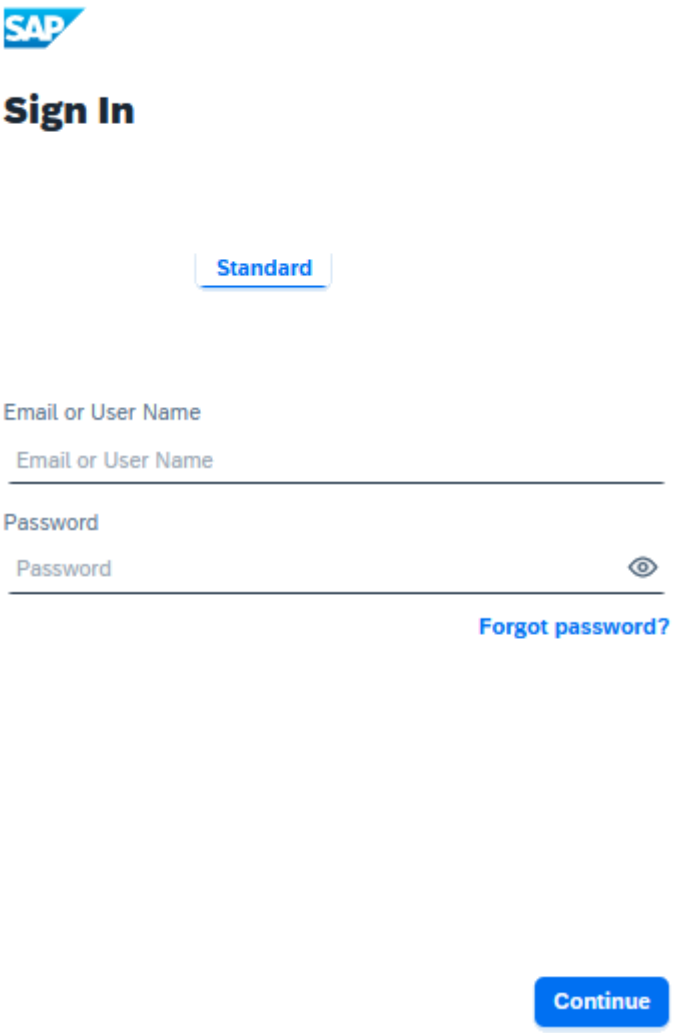
Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

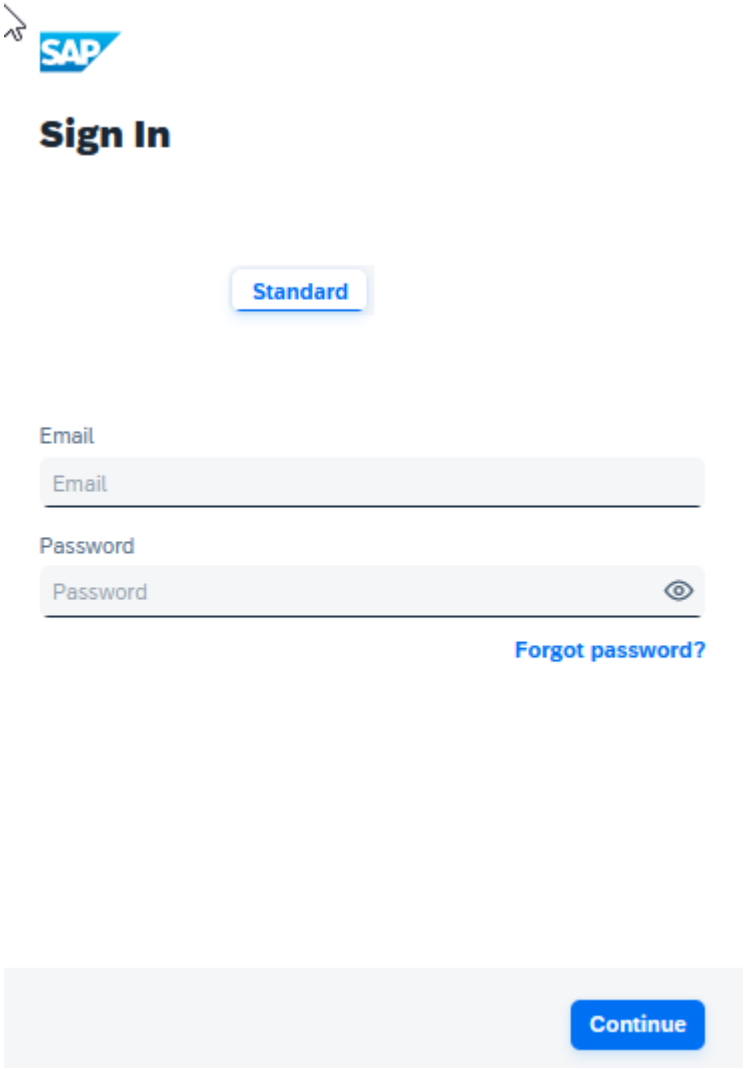
Context

The predefined tenant texts are listed in the administration console for SAP Cloud Identity Services. The texts are classified by category, key, and default value. Each key stores the name of a parameter, and the corresponding value is the text that can be changed and updated as custom value. The keys are self-explanatory and indicate the category and where the texts are used. For example, the

`logon.ui.label.user=Email or User Name` key value pair is for the type of information that the user must provide to sign in to the application. On the *Sign In* screen you see:



If you want to change the user identifier text, you have to update the key value pair `logon.ui.label.user=Email or User Name` to `logon.ui.label.user=Email` to receive:



→ Tip

For more information about the allowed HTML elements in the tenant texts, see Change Tenant Texts REST API [page 2826].

You can browse for specific tenant texts and update only them.

You can also update the tenant texts that you want via a CSV file import for a specific language. The CSV file must contain the following columns: *category*,*key*,*defaultValue*,*customValue*.

You can use again the default tenant texts by simply resetting the custom texts. The *Reset to Default* operation resets all customized tenant texts to the default values.

→ Remember

It takes 2 minutes for the configuration changes to take place.

To change the tenant texts via the administration console, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Texts* tile.
3. Choose the language from the drop-down list.

   The default setting is English (United States).
4. Find the text that you want to change.

   You can use the search field, or the filtering and sorting option, or you can expand the page for more results.
5. Choose the *Edit* button.
6. Add the new text in the *Custom Value* field next to the text that you want to change. Repeat the step for all the texts that you want to change.

   > → Tip
   >
   > You can check the allowed elements at Tenant Texts Allowed HTML Elements [page 2857].
7. Save your changes.

   If the operation is successful, you receive the `Tenant Texts updated` message.

Results

The default tenant texts are changed with the custom ones. It may take up to 2 minutes for the changes to be applied.

1.7.2.6 Configure Master Data Texts Via Administration Console

The master data texts option can be used to configure the predefined master data for each resource in Identity Authentication via the administration console.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The predefined master data represents records in Identity Authentication that contain all relevant system data about a resource (Salutations, Functions, Departments, Company Relationships, Industries, Languages, Countries). That data can be used by the system for different classifications in the organization, for example, job titles, departments, or countries. The predefined master data texts are stored in `properties` documents, which can be accessed from the links in the table below.

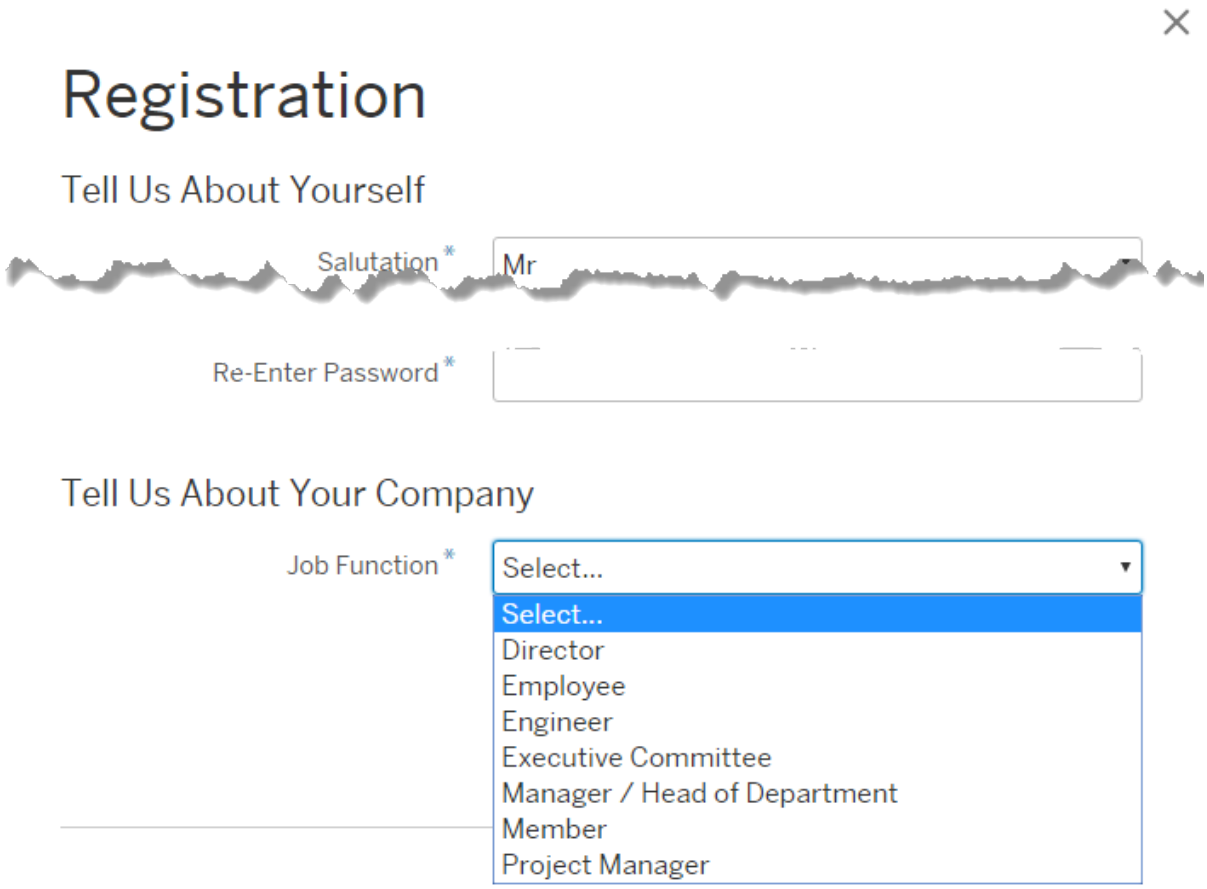
Predefined Master Data Texts

Resource	Link	Notes
Salutations	Salutations.properties [page 2868]	Key value pairs with a predefined set of honorifics.
Functions	Functions.properties [page 2868]	Key value pairs with a predefined set of job titles.
Departments	Departments.properties [page 2868]	Key value pairs with a predefined set of departments.
Company Relationships	Relationships.properties [page 2869]	Key value pairs with a predefined set of business entities, such as customer, partner, employee.
Industries	Industries.properties [page 2870]	Key value pairs with a predefined set of industries.
Languages	Languages.properties [page 2870]	Key value pairs with a predefined set of languages.
Countries	Countries.properties [page 2873]	Key value pairs with a predefined set of countries.

The files contain configurable parameters stored as key value pairs of strings. Each key stores the unified key of the resource, and the corresponding value is the unified value of the resource that can be changed and updated.

The key value pairs are also visible in the administration console under the corresponding tabs.

The example below shows the customized values of the *Functions* file. The dropdown list in the *Job Function* field on the *Registration* form shows the new values that have overwritten the predefined texts in the file.



Depending on your requirements, you can review the texts that you have already overwritten in the predefined master data texts, change or delete existing key value pairs, add new key value pairs, or reset the texts to the default key value pairs.

> ⚠ Caution
>
> Be careful if you change the keys when overwriting data texts, because this can result in invalid values. If a user has a certain value assigned, and the key value pair is overwritten with a different key, then the value for that property of the user will be no longer valid and visualized. For example, if you have set "Mr." to a user, and the key-value pair is "01=Mr.". If you overwrite the key value pair with "03=Mr.", "Mr." will not be visualized for that user.
>
> When overwriting data texts, the keys for the different languages must be one and the same. For example, the master data texts for the German locale are overwritten, and the tenant administrator wants to overwrite the texts for the French locale. The keys for the German locale must be used as keys for the French locale.

The master data is sent in the SAML 2.0 assertion or OpenID Connect (OIDC) token with its key. For example:

```
<Attribute Name="salutation">
            <AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">0002</
AttributeValue>
</Attribute>
```

→ Remember

It takes 2 minutes for the configuration changes to take place.

To change the master data texts via the administration console, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Master Data* tile.
3. Choose the language from the drop-down list.

   The default setting is English (United States).
4. Choose the tab with the resource that you want.
5. Find the text that you want to change.

   You can use the search field, or the sorting option, or you can expand the page for more results.
6. You have the following options:
   - Change existing texts - Choose the *Edit* button, find the text that you want to change, and replace it in the *Value* field with the new text. You can use the search field, or the sorting option, or you can expand the page for more results.
   - Reset to default values- Choose the *Reset to Default* button. This action resets all master data texts from the chosen resource to their key value pairs.
   - Add a new key value pair - Choose the *Add* button and provide key and value.

     ⓘ Note

     You can't enter duplicate keys.
   - Delete key value pairs - Find the key value pair that you want to delete, select the checkbox next to it and choose the *Delete* button.
7. Save your changes.

1.7.2.7 Configure Links Section on Sign-In Screen

You can configure links to appear on the sign-in screen of your applications.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

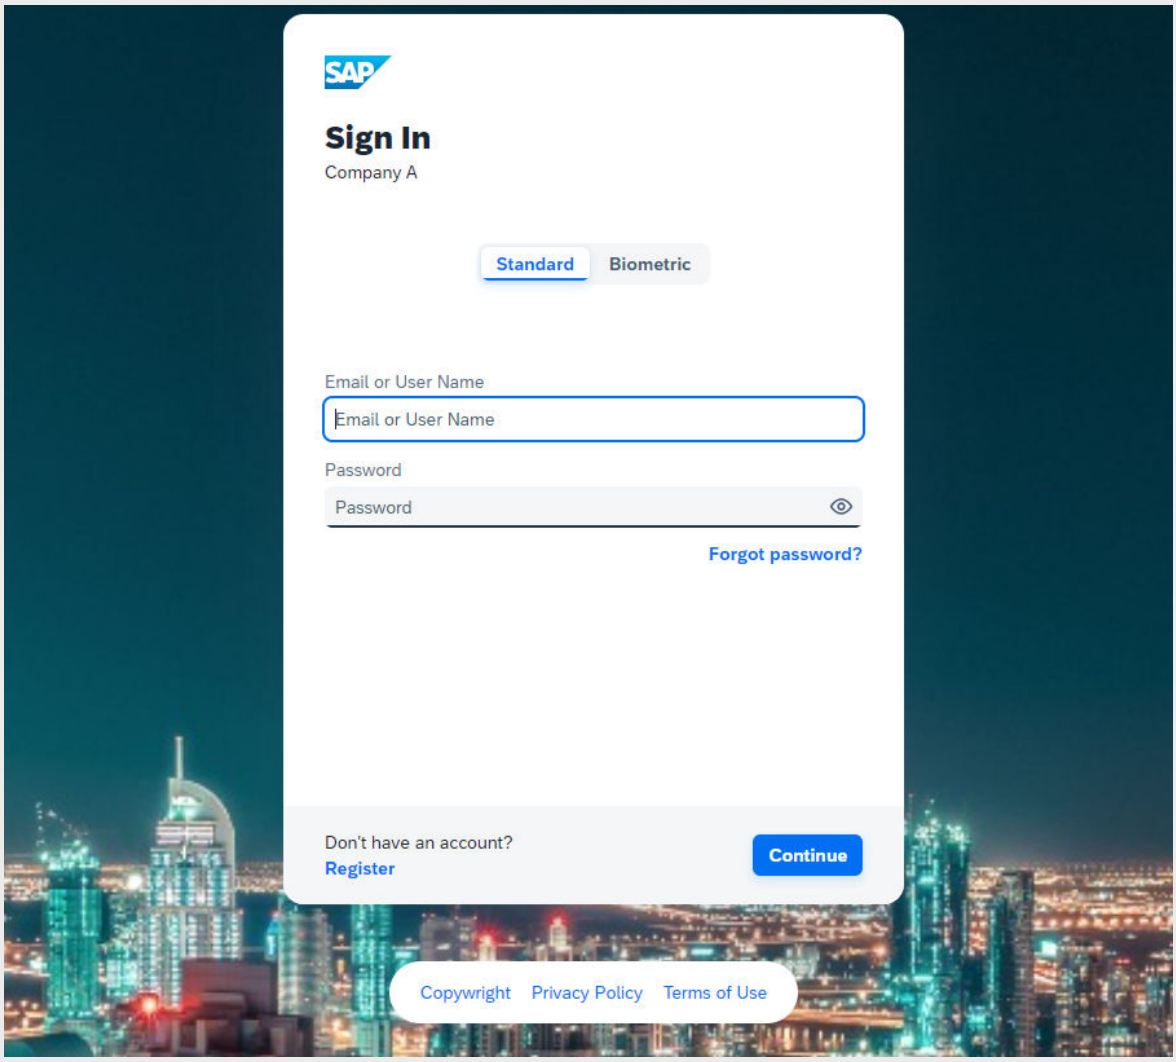
Context

Logon links can be configured via the change tenant texts option in the administration console. Tenant administrator can add three types of links on the logon screen:

- logon.ui.copyright.link - Default Copyright link
- logon.ui.privacy.link - Default Privacy link
- logon.ui.legal.disclosure.link - Default Legal Disclosure link

The default values of the logon link keys are empty and no links are displayed. New values must be in the format `<a href="link_URL">Link Text</a>`, for example `<a href="https://www.example.com" >Privacy Policy</a>`.

Example



The configured links appear on the logon screens of all applications in the tenant.

You can return to the default configuration by resetting the custom texts. The *Reset to Default* operation resets all customized tenant texts to the default values.

> **Note**
>
> If the texts are configured for English (United States) and not configured for another language, and user uses browser with locale that language, the user sees texts customized for English (United States).
>
> > **→ Remember**
> >
> > It takes 2 minutes for the configuration changes to take place.

To configure your logon links, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Texts* tile.
3. Choose the language from the drop-down list.

   The default setting is English (United States).
4. Find the text that you want to change.

   You can use the search field, or the filtering and sorting option, or you can expand the page for more results. The keys for the links are:

Category	Key
Logon	logon.ui.copyright.link
Logon	logon.ui.privacy.link
Logon	logon.ui.legal.disclosure.link

5. Choose *Edit*.
6. Add the new text in the *Custom Value* field next to the text that you want to change.

   > **Note**
   >
   > The value must be in the format `<a href="https:link_URL">Link Text</a>`.
7. Save your changes.

   If the operation is successful, you receive the `Tenant Texts updated` message.

1.7.2.8 Add Instructions Section on Sign-In Screen

You can customize the sign-in screen of the *Horizon* theme with instructions for the user.

Prerequisites

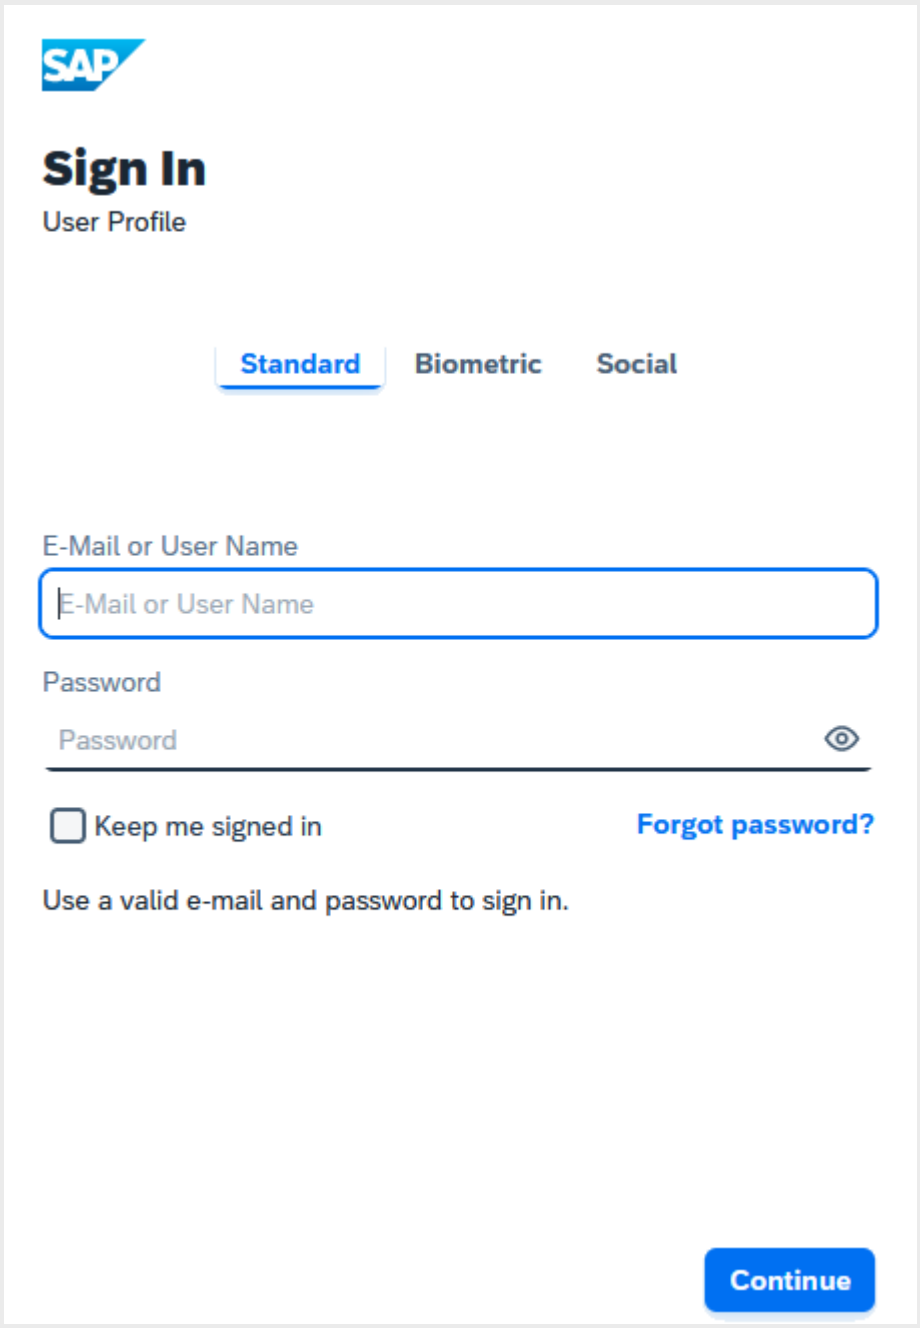
You have chosen the *Horizon* theme for the sign-in screen of your application. For more information, see Choose and Configure a Branding Style for an Application [page 2035].

Context

The section with instructions on the sign-in screen can be configured via the change tenant texts option in the administration console. Tenant administrator can add the section by configuring the `logon.ui.login.instructions` key.

The default value of the `logon.ui.login.instructions` key is empty and nothing is displayed. New values can include text and links.

Example



Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Texts* tile.
3. Choose the language from the drop-down list.

The default setting is English (United States).

4. Find the text that you want to change.

   You can use the search field, or the filtering and sorting option, or you can expand the page for more results. The key for the instruction is: `logon.ui.login.instructions`.

5. Add the new text in the *Custom Value* field.
6. Save your changes.

   If the operation is successful, you receive the `Tenant Texts updated` message.

1.7.2.9 Configure X.509 Client Certificates for User Authentication

Tenant administrators can configure X.509 client certificates for user authentication as an alternative to authenticating with a user name and a password.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

User authentication with a trusted X.509 certificate takes place using the underlying Secure Sockets Layer (SSL) protocol and users don't need to enter a password for their logon.

Certificates for API Authentication cannot be used for user authentication.

Remember that it may take between two and four weeks to enable the certificate.

> ⓘ Note
>
> If you want to configure a certificate, using your own trusted CA, for example for scenarios like authentication of technical users or OAuth clients, skip the procedure in this document and report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`. Attach to the incident the root and intermediate certificates and provide the Identity Authentication tenant host.
>
> If you already have a trusted CA added to your tenant, but after that a custom domain has been configured for that tenant, report a new incident on SAP Support Portal Home with a component `BC-IAM-IDS` to update the certificate on the custom domain as well.

> ⚠ Caution
>
> If the users have generated their own certificates via the profile page, they won't be able to authenticate with the configured X.509 client certificate, and vice versa.

Edit and Delete Certificates

If you want to edit an already configured certificate, choose certificate, choose the *Edit* button, make your changes and save them.

> → Remember
>
> If you have made changes to the root certificate, report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`, attach to the incident the root and intermediate certificates, and provide the Identity Authentication tenant host.

If you want to delete an already configured certificate, choose the certificate, choose the *Delete* button, and report an incident on SAP Support Portal Home with a component `BC-IAM-IDS` providing the Identity Authentication tenant host.

To configure a trusted X.509 certificate, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Trusted Certificate Configuration* list item.
4. Choose the *+Add* button.
5. Enter the name of the certificate.

   > ⓘ Note
   >
   > The name and the *Subject DN* must be unique.
6. Choose one of the following options:

Certificate Options	Notes
Upload Certificate	The uploaded certificates must be in **PEM** format. Use `.cer` or `.crt` files.
Root Certificate	Insert the public key in the text field.

7. Choose one of the following source options:
   - *Distinguished Name* - If selected *Distinguished Name* as source, the pattern must match the *Subject DN* of the user certificate. The *CN* attribute from the *DN Pattern* can take the following formats:
     - `CN=${<logonIdentifier>}`. In this case the CN must completely map to one of the supported logon identifiers, `loginName`, `uid`, and `mail`.

       > ✤ Example
       >
       > CN=${loginName},O=Management,C=US.
     - `CN=${mail:<user_email>}`. This case allows you to specify a unique DN pattern for single user authentication.

> **Example**
>
> CN=${mail:dona.moore@example.com},O=Management,C=US.

- *Subject Alternative Name - Other Name* - If selected *Subject Alternative Name - Other Name*, the pattern must match the `subjectAltName` extension entry of type `otherName` (Microsoft User Principal Name form) of the user certificate. The pattern for SAN value must be in format `${<logonIdentifier>}` and must completely map to one of the supported logon identifiers, `loginName`, `uid`, and `mail`.

  > **Example**
  >
  > `${loginName}`

- *Subject Alternative Name - Email (RFC822 Name)* - If selected *Subject Alternative Name - Email (RFC822 Name)*, the pattern must match the `subjectAltName` extension entry of type `rfc822Name` of the user certificate. The pattern for SAN value must be in format `${mail}`.

Two configurations with different source options in one Identity Authentication tenant are not supported.

8. Enter the *Pattern* of the certificate.

> **Note**
>
> If you want to log on with a certificate where the common name contains the user ID (for example: `Subject DN: CN=P000000,O=MyOrg,C=US`) then the pattern value must be: `CN=${uid},O=MyOrg,C=US`.
>
> If you want to log on with a certificate where the common name contains the email of the user (for example: `Subject DN: CN=my_email@example.com,O=MyORG,C=US`), then the pattern value must be: `CN=${mail},O=M,C=US`.

9. Choose the *+Add* button.
10. To add the certificate to your tenant, report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`. The SAP Cloud Root CA certificates are trusted by default.
    a. Attach to the incident the root and intermediate certificates.
    b. Provide the Identity Authentication tenant host.

> **→ Remember**
>
> The following certificates are trusted by default:

CA Display Name	Subject	Serial number	Expiry Date MM-DD-YYYY
SAP Cloud Root CA	CN=SAP Cloud Root CA, O=SAP SE, L=Walldorf, C=DE	18 77 0f be 65 06 6b bf 4c ea 93 38 d9 b1 85 62	02-13-2039
DigiCert Global Root CA	CN=DigiCert Global Root CA, OU=www.digicert.com, O=DigiCert Inc, C=US	08 3b e0 56 90 42 46 b1 a1 75 6a c9 59 91 c7 4a	11-10-2031

CA Display Name	Subject	Serial number	Expiry Date MM-DD-YYYY

1.7.2.10 Enable Users to Generate and Authenticate with Certificates

Allow users to generate and authenticate with certificates.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

By enabling certificate generation and authentication for the users, they can log on to applications with the generated certificate without the need to provide username and password.

The tenant administrator can configure the system to allow the following types of users to generate their own certificates via the profile page and to authenticate with them:

- *Public*
- *Customer*
- *Partner*
- *Employee*

The certificate generation and authentication is disabled by default for all user types. When you allow it for a user type, the user of this type should go to the profile page and generate a certificate for authentication. Once the certificate is generated, it's downloaded to the user's system. When the user imports it to the certificate store or browser, the newly generated certificate is ready for authentication. When the user navigates to the logon page of the application, he or she is automatically authenticated with the certificate. If the authentication fails, the user is prompted to provide username and password.

> ⚠ Caution
>
> If you have an already configured X.509 client certificate used for user authentication, the users won't be able to authenticate with their own certificates generated via the profile page, and vice versa.

To allow certificate generation and authentication, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Certificate Authentication* list item.
4. Use the slider next to a user type to enable certificate authentication.

   If the operation is successful, you receive a confirmation message.

Next Steps

Enable the *Credential change* security alert emailing to inform the user when a certificate generated or removed. For more information, see Send Security Alert Emails [page 2209].

1.7.2.11 Configure Tenant Images

You can configure a custom global logo and, or a background image on the forms for sign-in in, registration, upgrade, password update, and account activation for all applications in a tenant. You can also set a favicon for tenant.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- (for the background image only) - You use the *Horizon* theme for your application. For more information, see Choose and Configure a Branding Style for an Application [page 2035].

Context

Logo

The logo is displayed in the footer or header of the form that your users access to sign in or to register to an application. If you don't specify a company-specific tenant logo, the forms display the default SAP logo. SAP has configured the following default tenant logo.

You can use an image with a maximum height of 36 pixels.

> ⓘ Note
>
> If the height of the image is larger than 36 pixels, the user forms show the logo proportionally resized to a height of 36 pixels. Thus, the quality will be preserved.
>
> If the height of the image is lower than 36 pixels, the user forms resize the image. Otherwise, the quality is deteriorated.

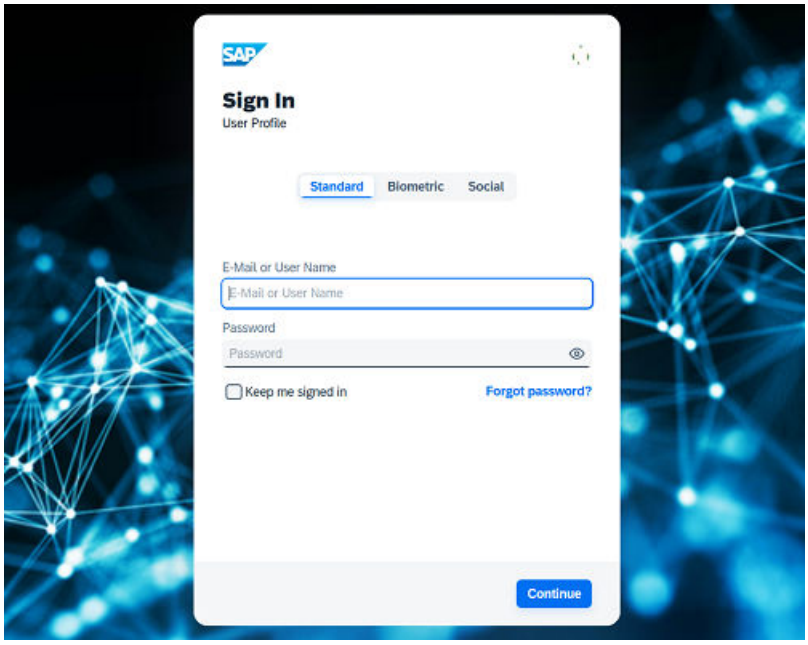
The image file must have one of the following extensions: `.png`, `.gif`, `.jpeg`, or `svg`.

> ⚠ Caution
>
> If the image is of format <svg>, please make sure that the attribute `viewBox = "min-x min-y width height"` is present. For proper rendering the width and height values must not exceed 100. For example, `viewBox="0 0 100 100"`

Background Image

> ⓘ Note
>
> The background image is applied only to applications that use the *Horizon* theme. For more information about the *Horizon* theme, see Choose and Configure a Branding Style for an Application [page 2035].

The background image is displayed behind the form that your users access to sign in or to register to an application.



If you do not specify a background image, the forms won't display anything.

The image file must have one of the following extensions: `.png`, or `.jpg`.

You can use an image with a maximum size of 600 KB (1920x1080 pixels)

> → Remember
>
> The background image option is limited to mobile devices with minimum height of 599 pixels.

Identity Authentication doesn't store old versions the image. Once you upload a new image, the previous image is deleted.

Favicon

Favicon is a shortcut icon in a browser's address bar, for browsers that support them. Browsers that provide favicon support typically display the favicon for a page in the browser's address bar and next to the page title on the tab. Browsers that support a tabbed document interface typically show a favicon for a page next to the page title on the tab. You can upload a file for a custom favicon of Identity Authentication.

The image file must have one of the following extensions: `.png`, or `.jpg` with a maximum size of 100 KB (max 100x100 pixels).

To configure a custom tenant logo a background image, and or a favicon, follow procedure below. It takes up to 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.

3. Under *Custonization*, choose the *Logo, Background Image and Favicon* list item.
4. **Optional:** Choose the *Logo* tab, upload an image, and save your configuration.

   If the operation is successful, you receive the following message: `Tenant logo updated`.

   > → Tip
   >
   > To restore the default logo, choose *Restore Default*.
   >
   > If this operation is successful, you receive the following message: `Default logo restored`.

5. **Optional:** Choose the *Background Image* tab, upload an image, and save your configuration.

   If the operation is successful, you can see the image applied together with the following message: `Tenant Background Image updated`.

   > → Tip
   >
   > To delete the background image, choose the *Delete* button.
   >
   > If this operation is successful, you receive the following message: `Background image deleted`.

6. **Optional:** Choose the *Favicon* tab, upload an image, and save your configuration.

   If the operation is successful, you can see the image applied together with the following message: Tenant Favicon updated.

Configure P-User Next Index [page 2220]
Reuse SAP Cloud Identity Services Tenants for Different Customer IDs [page 2222]

1.7.2.12 Configure Allowed Logon Identifiers

Tenant administrators can choose the allowed logon identifiers for the users.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Choose the allowed logon identifier for your users. Once set, the configuration is valid for all applications in the tenant. The options are *User ID*, *Login Name*, *Email*, and *Phone*. *Display Name* is not configurable.

Default Configuration

The default configuration for newly created tenants is the following:

Default Configuration

Logon Identifier	Configuration
User ID	*Off/Configurable*
Login Name	*On/Configurable*

Logon Identifier	Configuration
Email	*On/Configurable* **Note** The email user identifier must be selected unique if you use it for: • logon • sending security alert emails to end-users or administrators when a registration with nonunique email is carried out For more information, see Next Steps at the end.
Display Name	*Off/Not Configurable* **Note** Not allowed for logon.
Phone	*Off/Configurable* **Note** The phone user identifier must be selected unique if you use it for logon. For more information, see Next Steps.

Users can log on only with the enabled logon identifiers.

→ Remember

The logon identifier choice in the administration console does not affect the following scenarios:

- Corporate User Store
- Conditional Authentication
- Forgot Password
- X.509 Client Certificates for User Authentication
- Kerberos Authentication

→ Tip

The texts on the logon screen are predefined. If you change the logon identifiers preference in the tenant, this will not automatically change the text in the logon page. For example if you enable only *Email* as logon identifier, but your previous configuration included *User ID*, *Login Name*, and *Email* the text on the logon screen will remain unchanged.

To change the text, you must update the predefined texts and messages for end-user screens available per tenant in the Identity Authentication. For more information, see Change Tenant Texts REST API [page 2826].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

If you want to change the allowed logon identifiers for your tenant, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Logon Alias* list item.
4. Enable or disable the options according to your needs.

   > → Remember
   >
   > You must choose at least one logon identifier.

   If the operation is successful, the system displays the message `Logon alias updated`.

Results

Users can logon to the applications in the tenant only with the selected logon identifiers.

Next Steps

- Change the predefined texts to match the changed logon identifiers. For more information, see Change Tenant Texts REST API [page 2826].
- Configure the user identifier attributes as required and unique. For more information, see Configure User Identifier Attributes [page 2149].

1.7.2.13 Configure User Identifier Attributes

Tenant administrators can configure user identifier attributes as required and unique for the tenant.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Identity Authentication ensures the uniqueness only of the newly set values of the attributes. The system doesn't guarantee the uniqueness of the existing attributes.

The default configuration for the user identifiers are:

User Identifier Default Configuration

User Identifier	Required	Unique
User ID	Yes/Not Configurable	Yes/Not Configurable
Email	Yes/Configurable	Yes/Configurable
Login Name	No/Configurable	Yes/Not Configurable
Display Name	No/Configurable	No/Configurable
Phone	No/Not Configurable	No/Configurable

⚠ Caution

The `User ID` and `Login Name` identifiers of a user can't have values that are equal to the `User ID`, `Email`, `Login Name`, `Display Name`, and `Phone` identifiers of another user.

When `Email` or `Phone` identifiers of a user are set as unique they can't have values that are equal to the `User ID`, `Email`, `Login Name`, `Display Name`, and `Phone` identifiers of another user.

→ Remember

If the `DisplayName` is edited via the profile page, consider the following:

- When the `Display Name` identifier of a user is set as unique it can't have values that are equal to the `User ID`, `Global User ID`, `Email`, `Display Name`, `Login Name`, and `Employee Number` identifiers of another user.
- When the `Display Name` identifier of a user is set as non-unique it can't have values equal to the `User ID`, `Global User ID`, `Email`, `Login Name`, and `Employee Number` identifiers of another user.

ⓘ Note

The `Display Name` user identifier for the tenants created before the system upgrade on May 13, 2020 is configured as required and unique.

The `Phone` user attribute is configured as non-unique by default. If you configure it as unique, all users that are created or updated after this configuration won't be able to have phone numbers taken by someone else.

→ Remember

If `Email` is marked as not-required on tenant level, it becomes configurable on application level, and must also be changed there, too. For more information, see Configure Registration and Upgrade Forms [page 2046].

Email Required/Unique Configurations

Choice	Yes	No
Required	• admin must provide email when creating or editing user in the admin console • `emails.value` attribute is mandatory when creating a user via the SCIM REST API • email appears as required in the registration form of an application • user must provide email, if missing, when an update of the account is triggered • admin can't delete user's email in admin console • user can't delete his/her email in profile page	• admin must provide email when creating user in the admin console only when account activation is *Send activation email* • `emails.value` attribute must be provided when creating a user via the SCIM REST API only when `sendMail` attribute is *true* • email is required in the registration form of the application; the configuration is taken into account for the upgrade process • reset password process will be replaced by change password process for users with no email • user is not prompted to provide email, if missing, when an update of the account is triggered • admin can delete user's email in admin console • user can delete his/her email in profile page • end-user screen texts differ from the actual tenant configuration; admin can change the tenant texts to match the configuration • email verification setting for an application could be skipped for users with no email.

Choice	Yes	No
Unique	• email can be used for logon • email must be unique for security alert emails when a registration with nonunique email is carried out • email must be unique, if provided, when a user is created or edited via the admin console • `emails.value` attribute must be unique, if provided, when a user is created via SCIM REST API • user must provide unique email, if required, when an update of the account is triggered • user import is supported; email must be provided • `email` attribute must be unique, if provided, when a user is registered via User Management REST API **Note** The email user identifier must be selected unique if you use it for logon. For more information about how to configure the allowed logon identifiers, see Next Steps.	• email can't be used for logon • admin can create more than one user with one and the same email in the admin console • `emails.value` attribute may not be unique if provided when a user is created via SCIM REST API • email, if required, may not be unique when an update of the account is triggered • users with non-unique emails can't change their password via the *Forgot Password* process using the email as identifier • end-user screen texts differ from the actual tenant configuration; admin can change the tenant texts to match the configuration • user import is not supported

The texts on the end screen are predefined. If you change the required/unique preference in the tenant, this won't automatically change the texts in the end-user page. To change the text, you must update the predefined texts and messages for end-user screens available per tenant in the Identity Authentication. For more information, see Change Tenant Texts REST API [page 2826].

Although the choice for the `required` attribute is applied for all applications in the tenant, you can still make the *Email* required on the registration and upgrade form for specific applications via a custom configuration. For more information, see Configure Registration and Upgrade Forms [page 2046]

→ Remember

It takes 2 minutes for the configuration changes to take place.

If you want to change the configuration for the user identifier for your tenant, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.

3. Under *Authentication*, choose the *Logon Alias* list item.
4. Select the options for the user identifier according to your needs.
    - Required
    - Unique

    If the operation is successful, the system displays the message `Logon alias updated`. It takes two minutes for the change to be applied.

Next Steps

Choose the allowed logon identifiers for the users. For more information, see Configure Allowed Logon Identifiers [page 2146].

1.7.2.14 Configure *Trust this browser* Option

Tenant administrator can set the number of days for which the users won't get prompted for second-factor authentication, if they sign in from the same browser.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The validity of *Trust this browser* can be set between 1 and 14 days.

If the option for trust this browser is set at *Disabled*, and a user chooses to always provide second factor when authenticating, the validity of *Trust this browser* is 3 months. But if the administrator sets a validity from 1 to 14 days, the 3-month validity is overridden with the validity set by the tenant administrator.

The *Trust this browser* checkbox appears at sign-in when a second factor is required for the users. When users chose the *Trust this browser* checkbox, the second factor is required only with the first sign-in. The validity depends on the configuration in the administration console.

> **Note**
>
> If the device for time-based one-time password (TOTP) or Web Two-Factor Authentication is deactivated, all the related tokens for the user will be removed.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Multi-Factor Authentication* list item.
4. Under *Additional Settings for Multi-Factor Authentication*, choose *Edit*.
5. Under *Trusted Browser Setting for Users*, choose *Enabled*.
6. Manually configure the number of days for which users will not get prompted for second-factor authentication, if they sign in from the same browser.
7. Save your changes.

   If the operation is successful, the system displays the message `Additional Multi-Factor Authentication Settings updated`.

1.7.2.15 Enable Back-Up Channels to Send Passcode for Deactivation of TOTP Two-Factor Authentication Devices

Tenant administrator can configure back-up channels to send TOTP deactivation passcodes to the user.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- (for the SMS channel) The user must have a verified phone.
- (for the SMS channel) You have configured the Sinch Service option in the administration console for SAP Cloud Identity Services. For more information, see Configure Sinch Service in Administration Console [page 2051].
- (for the email channel) The user must have a verified email address.
- (for the email channel) You have configured an email template for the *Deactivate TOTP Device* process. For more information, see Configuring Email Templates [page 2282].

> → Remember
>
> The *${other.totpResetPasscode}* parameter is mandatory for the *Deactivate TOTP Device* template.

Context

The primary channel to deactivate a device is the passcode generated by the mobile device. If no other back-up channel is enabled, this option is the only one for the user in the *Two-Factor Authentication* section of the administration console for SAP Cloud Identity Services.

When the back-up channels, *SMS* and/or *Email* are enabled in the administration console, the user can choose from the options on the profile page: *Existing Multi-Factor Authentication*, *Passcode by SMS*, and *Passcode by Email*.

> → Tip
>
> We recommend you to enable the back-up channels. Thus the users can use the option as an alternative when they don't have access to the TOTP device or application.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To enable or disable back-up channels for deactivation passcode, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Multi-Factor Authentication* list item.
4. Under *TOTP Deactivation Passcode Channels Configuration*, enable or disable the options according to your needs.
   - *SMS*
   - *Email*

   If the operation is successful, the system displays the message `TOTP Deactivation Options updated`.

Results

Users can choose from the back-up channel options on their profile page if they are enabled via the administration console.

1.7.2.16.1 Enable Users to Recover Password with Security Questions

Users can choose to answer security questions to reset their password.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

You can configure the applications in the tenant to allow users to answer security questions to reset their password instead of receiving an email with a reset password link.

For this setup, you as a tenant administrator, configure the security questions option in the *Tenant Settings* section in the administration console, and the users configure their answers in the profile page. Once the security questions and answers are configured, the user can use this option to reset the password. The user must have configured their answers in the profile page to be able to reset password via security questions.

> ⚠ Caution
>
> The answers to the security questions are case sensitive.

If the security questions option is configured in the admin console, end users that haven't set up their security questions are triggered to do it as a post logon step. Optionally, they can choose to set up the security questions later. If end users choose the *Don't ask me again* check box, the prompt won't be shown anymore. End users still can set up the security questions in their profile page.

> ⓘ Note
>
> You can choose whether the *Setup later* and *Don't ask me again* options are visible for the end users.

Tenant administrator can offer up to 10 predefined questions, and can choose which target users to be able to reset their password via security questions. There are three options:

- *None* - the security questions option isn't offered to the users and all security questions configurations in the administration console are disabled
- *Users without email* - only users that don't have emails can reset password via security questions.
- *All users* - everyone can choose this option to reset the password

- *Specific groups* - only users that belong to the selected groups can reset password via security questions.

If *Home URL* is configured, users are redirected to the URL defined in the *Home URL* after resetting their passwords via Security Questions. If *Home URL* is not configured users are redirected to the profile page.

> ⚠ Caution
>
> The security questions option locks after five wrong answers to the security questions. To unlock it, set an initial password for the user. For more information, see Set Initial Password [page 2384].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To configure security questions in the administration console, follow the procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Password Recovery* list item.
4. Choose the *Security Questions* tab.
5. Choose *Edit* > *Enabled* .
6. Under *Target Users*, choose users that can reset passwords with security questions:
   - *None* - default choice

     > ⓘ Note
     >
     > If selected, the security questions configurations in the administration console are disabled
   - *Users without email*
   - *All users*
   - *Specific groups*

     > ⚠ Restriction
     >
     > The administrator must be assigned the *Manage Groups* role or be part of a policy that allows reading groups to be able to view the groups in the list. For more information, see Edit Administrator Authorizations [page 2309] or Configure Group Authorizations [page 2320].

     > ⓘ Note
     >
     > When you select this option, you must specify the specific group or groups for which you enable password recovery via security questions.
7. Under *Number of Security Questions*, choose how many questions the user must answer.

8. **Optional:** Under *User Options*, select the *Show "Setup later"* check box.

   When selected, the end users see the option to setup the security questions later.
9. **Optional:** Under *User Options*, select the *Show "Don't ask again"* check box.

   When selected, the end users see the option to hide the prompt to setup their security questions later.
10. Save your configuration.

    You can see information about your settings and the 10 predefined questions the user can choose from..

Enable Users to Reset Password via Profile Page [page 2166]

1.7.2.16.2 Enable Users to Recover Password with PIN Code

Users can choose to provide PIN code to reset their password.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

> ⚠ Caution
>
> For security reasons, the PIN Code is not a recommended password recovery method. The users can follow the *Forgot Password* link on the sign in page to reset their password via email.

You can configure the applications in the tenant to allow users to provide PIN code to reset their password instead of receiving an email with a reset password link.

For this setup, you as a tenant administrator, configure the PIN code option in the *Tenant Settings* section in the administration console, and the users set their PIN code in the profile page.

Once the PIN code is configured, the user can use this option to reset the password. The user must have set their PIN code in the profile page to be able to reset password via this option.

If the PIN code option is configured in the admin console, end users that haven't set up their PIN code are triggered to do it as a post logon step. Optionally, they can choose to set up the PIN code later.

If end users choose the *Don't ask me again* check box, the prompt won't be shown anymore. End users still can set up the PIN code in their profile page.

PIN Code Characteristics

Characteristics	Notes
Allowed Characters	Base 10 digits (0-9)
Min Length	Between 4 and 32 characters; configurable on tenant level
Max Length	32 characters
Required	*Setup later* and *Don't ask me again* are configurable
Target Users	• *Users without email* - only users that don't have emails are able to reset password via PIN code • *All users* - everyone can choose this option to reset the password • *Specific groups* - only users that belong to the selected groups can reset password via PIN code.
Lock	The reset password action with PIN code locks after 5 failed attempts. The logon with correct username and password is not interrupted.
Unlock	To unlock the PIN code, set an initial password for the user.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To configure PIN code option in the administration console, follow the procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Password Recovery* list item.
4. Select the *PIN Code* tab.
5. Choose *Edit* > *Enabled* .
6. Under *Target Users*, choose users that can reset passwords with PIN code:
   - *Users without email*
   - *All users* - default choice
   - *Specific groups*

> ⚠ Restriction
>
> The administrator must be assigned the *Manage Groups* role or be part of a policy that allows reading groups to be able to view the groups in the list. For more information, see Edit Administrator Authorizations [page 2309] or Configure Group Authorizations [page 2320].

> ⓘ Note
>
> When you select this option, you must specify the specific group or groups for which you enable password recovery via PIN code.

7. Under *PIN Length*, choose the minimum required length of the PIN code.
8. **Optional:** Under *User Options*, select the *Show "Setup later"* check box.

   When selected, the end users see the option to set up the PIN code later.
9. **Optional:** Under *User Options*, select the *Show "Don't ask again"* check box.

   When selected, the end users see the option to hide the prompt to set up their PIN code.
10. Save your configuration.

    You can see information about your settings.

Enable Users to Reset Password via Profile Page [page 2166]

1.7.2.16.3 Enable Users to Recover Password via Email

Users can choose to receive a link via email to reset their password.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The *Email* option in the administration console is enabled by default. If the *Email* option is enabled and *Profile Page* option is disabled, users can choose to receive a link via email to reset their password when they click the *Forgot password* link when they sign-in.

When the *Email* option is enabled and *Profile Page* option is disabled, users can also change their password directly in the profile page. When accessing the profile page, they see the *Change* button. By choosing *Change*, the user needs to provide the current and the new passwords to the system.

> → Remember
>
> If you disable the *Email* option, at least one of the other two password recovery options must be enabled for a user. Before you disable the email, view your other password recovery settings and select **`All users`** for *Target users*. For more information, see Enable Users to Recover Password with Security Questions [page 2160] or Enable Users to Recover Password with PIN Code [page 2162].

> ⚠ Caution
>
> Be careful also that if you disable the *Email* option, when the *Profile Page* option is enabled, both options will be disabled. For more information, see Enable Users to Reset Password via Profile Page [page 2166].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To enable the *Email* option in the administration console, follow the procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Password Recovery* list item.
4. Select the *Email* tab.
5. Choose *Edit* and select *Enabled*.
6. Save your configuration.

   You can see information about your settings.

Results

Users can choose to receive a link via email to reset their password when click the *Forgot password* link on the sign-in page.

> ⚠ Caution
>
> Be careful if you disable the *Email* option. Disabling the *Email* option when the *Profile Page* option is enabled will disable both options. For more information, see Enable Users to Reset Password via Profile Page [page 2166].

Task overview: Password Recovery Options [page 2158]

Enable Users to Recover Password with PIN Code [page 2162]
Enable Users to Reset Password via Profile Page [page 2166]

1.7.2.16.4 Enable Users to Reset Password via Profile Page

Enable the users to trigger reset password process via the profile page.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have enabled the *Email* option for password recovery in the administration console. For more information, see Enable Users to Recover Password via Email [page 2164]

Context

The *Profile Page* option is disabled by default. If the *Email* option is enabled and *Profile Page* option is disabled, users can change their password directly in the profile page. When accessing the profile page, they see the *Change* button. By choosing *Change*, the user needs to provide the current and the new passwords to the system.

Your scenario may require additional confirmation of the password change via email, before the new password is applied. You can do this by enabling the *Profile Page* option, which is visible only when the *Email* option is enabled. When accessing the profile page, users see the *Reset* button. By choosing *Reset*, the user triggers a manual password reset from the profile page. To reset the password the user must have an access to the email.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To enable the *Profile Page* option in the administration console, follow the procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Password Recovery* list item.
4. Select the *Email* tab.

   > → Remember
   >
   > Make sure that the *Email* option is enabled. If not, choose *Edit*, enable it, and save your changes.
5. Next to *Profile Page*, choose *Edit* and select *Enabled*.
6. Save your configuration.

   You can see information about your settings.

Results

When accessing the profile page, users see the *Change* button in the *Password* section.

1.7.2.17 Configure Initial Password and Email Link Validity

As a tenant administrator, you can configure the validity of the initial password and link sent to a user in the various application processes.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The tenant administrator can specify how long the link sent to a user in the various application processes will be valid for. The link in the email can be set to expire after between 1 and 23 hours, or 1 and 30 days.

Expired links can't be used. The system automatically sends a new link in an email when a user uses an expired link.

Identity Authentication has predefined the following validity periods:

Default Email Link Validity Periods

Application Process	Default Validity Period
Self-Registration	14 Days
On-Behalf Registration	14 Days
Invitation	14 Days
Forgot Password	2 Hours
Locked Password	2 Hours
Reset Password	2 Hours

The tenant administrator can also set a validity for the initial password. The initial password can be valid between 1 and 365 days depending on the configuration. The default value is 14 days. After the validity of the initial password expires, the user can't log on to the application and must contact the administrator.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To change the validity period of the initial password and the links, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose the *Initial Password and Email Link Validity* list item.
4. Choose *Edit*.
5. **Optional:** (For email link validity) Under *Configure Email Link Validity*, choose an application process and set the validity period of the email link for it.
   a. From the radio buttons on the right, select either *Days* or *Hours*.
   b. From the dropdown list on the left, select a number for this.

   > ⓘ Note
   >
   > You can choose a value between 1 and 23 for *Hours*, and 1 and 30 for *Days*.

   You can repeat the step for all processes.
6. **Optional:** (For initial password validity) Under *Configure Initial Password Validity*, set a value for the validity of the initial password.
7. Save your changes.

1.7.2.18 Configure Session Timeout

As a tenant administrator, you can configure when the session, created at the Identity Authentication tenant, expires.

Prerequisites

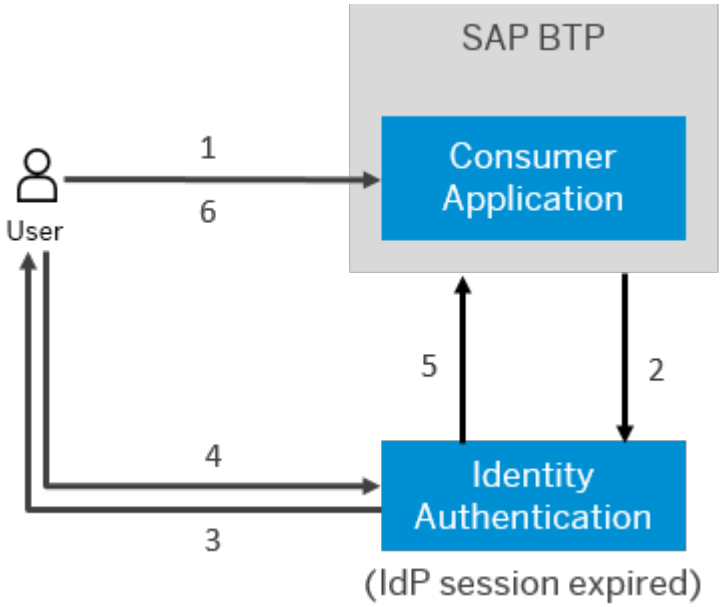
You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The session timeout feature enables closing of the session at the IdP when the configured period has passed. The configuration determines how long the IdP keeps the session alive.

By default, the timeout session for Identity Authentication is 12 hours.

When the IdP session has expired, and the application session has also expired, or the user tries to access a second application, Identity Authentication forces the user to provide his or her credentials.



1. Tries to access protected resource.
2. Sends request to check if the user has rights to access.
3. Opens Log On screen; forces user to provide credentials.
4. Provides credentials.
5. Grants access.
6. User accesses content.

> ⚠ Caution
>
> For OIDC applications, the Global Session Timeout acts as a hard upper bound on token validity. Access token lifetimes are capped at the remaining session duration, and refresh tokens cannot be issued or renewed beyond the active session, regardless of the token policy configured for the application or tenant. Exchanging a refresh token does not extend the session. If a refresh token is sent with one minute of session lifetime remaining, the resulting token is valid for one minute only.
>
> Configuring short session timeouts (for example, 15–30 minutes) can cause users to reauthenticate more frequently than expected in token-based integrations, even when the application's token policy is set to longer validity periods.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

To configure the session timeout period via the administration console for SAP Cloud Identity Services follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Single Sign-On*, choose the *Session Timeout* list item.
4. Set the session timeout period.
   a. From the dropdown list on the right, select either *Minutes* or *Hours*.
   b. From the dropdown list on the left, select a number for your choice.

   > ⓘ Note
   >
   > You can choose a value between *5* and *59* for *Minutes*, and *1* and *12* for *Hours*.
   >
   > The default value is *12* hours.
5. Save your changes.

   If the operation is successful, the system displays the message `Session timeout updated`.

1.7.2.19 Configure Trusted Domains

Service providers that delegate authentication to Identity Authentication can protect their applications when using embedded frames, also called overlays, or when allowing user self-registration.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

If you want to use overlays in your applications, you must add the domains of these applications as trusted in the administration console for SAP Cloud Identity Services. Otherwise the user will receive an error message when trying to access the overlays of these applications.

You also have to add as trusted the domains for those applications that allow self-registration to the users. For more information about the various access configurations in the administration console for SAP Cloud Identity Services, see Configure User Access to the Application [page 2025].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Customization*, choose the *Trusted Domains* list item.
4. Press the *+ Add* button.
5. Type the URL of the trusted host in the field.

   You can type either the full name of the host or you can use the wild card * function.

   > ⚠ Caution
   >
   > Be careful when using the wild card * function. Make sure that you trust the domain when you use it.

   See the examples:

   `mycompany.ondemand.com`

   `*.example.com`
6. Save your changes.

   If the operation is successful the system displays the message `Trusted Domains updated`.

1.7.2.20 Use Custom Domain in Identity Authentication

Identity Authentication allows you to use a custom domain that is different from the default ones (`<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`) - for example `www.mytenant.com`.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You must have a custom domain.

  > **Note**
  >
  > Internationalized domain names (IDNs) are not supported.

- You must have configured the CNAME DNS record on your domain to point to the host name used to access Identity Authentication. The host name can be one of the following, depending on where client's tenant is located:

  Host Names

Country/Region	Data Center	Infrastructure	Host Name
Australia	Australia (Sydney)	SAP / Azure	`ap.accounts.ondemand.com.cloud.sap.akadns.net`

Country/Region	Data Center	Infrastructure	Host Name
Brazil	Brazil (São Paulo)	AWS	`br.accounts.ondemand.com.cloud.sap.akadns.net`
China	China (Shanghai)	SAP	`accounts.sapcloud.cn.cloud.sap.akadns.net`
Europe	Germany (Frankfurt)	AWS	`aws-eu-de.accounts.ondemand.com.cloud.sap.akadns.net`
Europe	Europe (Frankfurt / Amsterdam))	SAP	`accounts.ondemand.com.cloud.sap.akadns.net`
India	India (Mumbai)	AWS	`aws-ap-in.accounts.ondemand.com.cloud.sap.akadns.net`
Israel	Israel (Tel Aviv)	Google Cloud	`il.accounts.ondemand.com.cloud.sap.akadns.net`
Japan	Japan (Tokyo / Osaka)	SAP	`jp.accounts.ondemand.com.cloud.sap.akadns.net`
North America (Canada Central)	Canada (Toronto)	Azure	`azr-na-ca.accounts.ondemand.com.cloud.sap.akadns.net`
Saudi Arabia (SA1)	Saudi Arabia (Dammam)	Google Cloud	`sa.accounts.ondemand.com.cloud.sap.akadns.net`
Saudi Arabia (SA2)	Saudi Arabia (Dammam) - Regulated	Google Cloud	`sa2.accounts.ondemand.com.cloud.sap.akadns.net`
Singapore	Singapore	AWS	`aws-ap-se-1.accounts.ondemand.com.cloud.sap.akadns.net`
South Korea	South Korea (Seoul)	AWS	`aws-ap-kr.accounts.ondemand.com.cloud.sap.akadns.net`

Country/Region	Data Center	Infrastructure	Host Name
Switzerland	Switzerland (Zürich)	Azure	`azr-eu-ch.accounts.ondemand.com.cloud.sap.akadns.net`
United Arab Emirates	United Arab Emirates (Dubai)	SAP	`azr-ap-ae.accounts.ondemand.com.cloud.sap.akadns.net`
United Kingdom	United Kingdom (London)	Azure	`uk.accounts.ondemand.com.cloud.sap.akadns.net`
US (North America East)	USA (Sterling, VA / N. Virginia)	SAP	`us-east.accounts.ondemand.com.cloud.sap.akadns.net`
US East **Note** Trial environment.	Trial (USA)	Azure	`trial-accounts.ondemand.com.cloud.sap.akadns.net`
US West	USA (Quincy, WA)	Azure	`azr-us-we.accounts.ondemand.com.cloud.sap.akadns.net`

Context

Note

If you have configured a custom domain and you want to add a deprecation trial token for third party cookies deprecation go to **Step 10**.

→ Remember

It takes 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.

3. Under *Customization*, choose the *Custom Domain* list item.
4. Provide the required information in the provided fields:

Field	Information
Domain	Host of your custom domain in lowercase
DN **Note** **The DN used for the domain certificate.**	• **CN** (CommonName) - mandatory **Note** The **CN** attribute must match the custom domain used for the domain certificate. • **OU** (OrganizationalUnit) - optional • **O** (Organization) - optional • **L** (Locality) - optional • **S** (StateOrProvinceName) - optional • **C** (CountryName) - optional

5. Save your configuration.
6. Choose the *Download CSR file* used for the domain certificate.
   a. Select the size of the certificate key. The supported key sizes are 2048, 3072 and 4096. The default value is 3072.
   b. **Optional:** Add an additional subject alternative name to the CSR.
   c. Choose the *Download* button and save the generated CSR file.

> **Note**
>
> Use this CSR for the custom domain certificate. Each download generates a new key pair for the CSR. Always use the last downloaded CSR file.

7. Send the CSR to a trusted Certificate Authority to sign the certificate.

> **Note**
>
> The supported algorithms are SHA-256, SHA-384 and SHA-512.

8. Access the tenant's administration console for SAP Cloud Identity Services > *Applications and Resources* > *Tenant Settings* > *Custom Domain* > *Certificate* and upload or insert as text the SSL certificate signed by the trusted CA.

> **Note**
>
> Make sure that the subject DN in the domain certificate and the configured subject DN match exactly.
>
> You can upload the domain certificate or the complete certificate chain. The certificate chain must contain the domain certificate, the intermediate certificate or certificates, and the trusted CA root certificate in the same order.

9. Save your configuration.
10. **Optional:** Add the third-party cookies deprecation trial token in the input field and save the configuration.

> → Tip
>
> For more information about how to get the third-party cookies deprecation trial token, see Deprecation trials .

Results

The custom domain configuration is enabled with the upgrade of Identity Authentication. We recommend you to renew your certificate as early as possible, preferably 30 days before expiration, and no later than the Sunday before productive system upgrade. Identity Authentication has production releases (bi-weekly updates) and immediate updates:

- **Bi-weekly updates** (standard)
  Standard updates are delivered on a bi-weekly basis. You can find the planned schedule for upcoming releases in the SAP Note 3409744 (Release Schedule for SAP Cloud Identity Services (SAP BTP)).
- **Immediate updates**
  Immediate updates are provided when fixes are required for issues that affect productive application operations or when urgent security fixes are necessary.

Next Steps

1. (Optional) Configure tenant's name to be the custom host. Select custom host for the name from the dropdown list in the SAML 2.0 or Open ID Connect Configuration settings. For more information, see Tenant SAML 2.0 Configurations [page 2103] Tenant OpenID Connect (OIDC) Configurations [page 2117].

   > ⚠ Caution
   >
   > After you select the custom host in the administration console, make sure that you also change the name of the identity provider on the service provider side, or the name of the identity provider on the corporate identity provider side. If you have set trusts with more than one service provider, or corporate identity provider, change the name in every provider, otherwise the trusts will not work. For more information about how to edit the name, see the documentation of the respective service or corporate identity providers.

2. Download the new SAML metadata of the identity provider (IdP). Configure the new metadata of the IdP in every application (service provider) you have set trusts with. For more information about how to configure the metadata, see the documentation of the respective service providers.
3. If have you configured social identity providers, please check configuration on the social provider side, and configure correctly the redirect URI, using the new custom host.
4. If have you configured a corporate identity provider, please update the configuration on the corporate identity provider side.
5. If you already have a trusted CA added to your tenant, but after that a custom domain has been configured for that tenant, report a new incident on SAP Support Portal Home with a component `BC-IAM-IDS` to update the certificate on the custom domain as well.

1.7.2.21 Change a Tenant's Display Name

You can configure the tenant's name from the administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Information about the tenant is visible in the header of the administration console. The information includes:

- The region, representing the location of data center in which the tenant is. For example, `Cloud Identity Services [Europe]`. This information is provided by the system, and cannot be edited by the tenant administrator. For more information about the regions, see Regional Availability [page 11].
- The tenant display name. This information can be edited. If you have not specified a specific tenant name, you will see the tenant ID instead. You can change the name to make it more understandable for you.
- → Remember

  It takes 2 minutes for the configuration changes to take place.

To edit the tenant's display name, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the edit icon next to the name of the tenant and change it.

   ⓘ Note

   The tenant display name must be between 1 and 50 characters long. You can use upper case (A-Z) and lower case (a-z) Latin characters, numbers 0-9, spaces, and the following symbols: _ - . '
4. Save your changes.
   Once the tenant has been updated, the system displays the message `Tenant <name of tenant> updated`.

1.7.2.22 Configure Default Risk-Based Authentication for All Applications in the Tenant

You can define rules for authentication according to different risk factors and apply actions like *Allow*, *Deny*, and *Two-Factor Authentication* for all applications in a tenant.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- (For *RADIUS Server Two-Factor Authentication*) You have requested this feature. For more information how to request and configure RADIUS server in Identity Authentication, see Configure RADIUS Server Settings (Beta) [page 2192].
- (For *SMS Two-Factor Authentication*) You have an account in Sinch. You have configured Sinch Verification in the administration console for Identity Authentication. For more information, see Configure Sinch Service in Administration Console [page 2051].

  > ⓘ Note
  >
  > Sinch Verification account is purchased separately. It is not part of the Identity Authentication contract.

- (For *Email OTP Code*) An Email OTP Code template for the respective languages must exist in the tenant to apply the email OTP code method. If the template does not exist, the user will see the option but when choosing it, the following message will appear: "Sorry, but you are currently not authorized for access". For more information how to add email templates, see Edit or Add an Email Template Set [page 2289].

Context

> ⚠ Caution
>
> Be careful when you set rules for authentication for the tenant. The rules apply to all applications in the tenant, including the `Administration Console`, if those applications have default risk-based authentication (no rules created; default action - Allow). The changes apply immediately when saved, and you may not be able to log in the `Administration Console` again if you don't meet the rules.

On the other hand, if a specific application has risk-based authentication different from the default one (no rules created; default action - Allow), and you apply default risk-based authentication for the tenant, the rules for the tenant won't apply to that specific application.

For more information, how to apply risk-based authentication for a specific application, see Configure Risk-Based Authentication for an Application [page 2007].

The configured rules manage authentication according to IP range (specified in CIDR notation), group membership, authentication method, and type of the authenticating user.

Authentication Rules

The created rules are displayed sorted by priority. When a user tries to access the application, the rules evaluate if the user meets the criteria of the rule. The evaluation starts with the rule with the highest priority, until the criteria of a rule are met. If the criteria of a rule are met, the rest of the rules are not evaluated.

Default Authentication Rule

If none of the authentication rules meets the criteria, the default authentication rule is applied, For the default authentication rule, you can only configure *Default Action*, which can be *Allow*, *Deny*, or *Two-Factor Authentication*.

> ⓘ Note
>
> If *Two-Factor Authentication* is selected, additionally, you must specify the two-factor method or methods for the user.

The rule is valid for any *IP range*, *Forwarded IP Range*, *Group*, *Authentication Method*, or *User Type*.

> ⓘ Note
>
> We recommend you to enable the back-up channels. Thus, the users can use the option as an alternative when they don't have access to the TOTP device or application. For more information, see Enable Back-Up Channels to Send Passcode for Deactivation of TOTP Two-Factor Authentication Devices [page 2156].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose *Risk-Based Authentication*.
4. **Optional:** Under *Authentication Rules*, configure the authentication rules by choosing one of the following options:

Option	Description
Create a new rule	See Create a New Rule for Risk-Based Authentication on Tenant Level [page 2186].
Edit an existing rule	Choose the icon next to the rule you want to edit.
Delete an existing rule	*Select the rule you want to delete* > *Delete*
Reprioritize rules	Choose *Edit* > *use the arrows to reprioritize the rules* > *Save*

> **Note**
>
> By default any user can log on from any IP.

5. **Optional:** Under *Default Authentication Rule*, configure the *Default Action*:
   a. Choose *Edit*.
   b. Choose from:
   - *Deny* - Nobody can log on.
   - *Two-Factor Authentication* - A drop-down appears when this choice is selected. You must specify the two-factor authentication method or methods for the end user.
6. Save your changes.

   Once the tenant has been updated, the system displays the message `Authentication rules updated`.

1.7.2.22.1 Create a New Rule for Risk-Based Authentication on Tenant Level

You can create rules for authentication according to different risk factors.

Context

> ⚠ Caution
>
> The rules apply on all applications in the tenant, including the `Administration Console` application. If you enable risk-based authentication for the tenant, make sure that you, as a tenant administrator, meet the authentication rules and the default authentication rule. The changes apply immediately when saved, and you may not be able to log in it again if you don't meet the rules.

Each rule contains the following information:

- **Authentication Action**
  This action is performed if the rule conditions meet the defined criteria.
  You can choose one of the following authenticating actions:
  - *Allow*
    Identity Authentication allows the authentication of the user in accordance with the rule conditions.
  - *Deny*
    Identity Authentication denies the authentication of the user in accordance with the rule conditions.
    You can set this action for a test application for example, or before an application goes live.
    As long as this rule is valid, when users try to log on to the application, they get the following message: *Sorry, but you are currently not authorized for access*.
  - *Two-Factor Authentication*

    > ⓘ Note
    >
    > If *Two-Factor Authentication* is selected, additionally, you must specify the two-factor method or methods for the user:
    > - *TOTP Two-Factor Authentication*
    >   Identity Authentication asks two factors to authenticate the user.

If you set TOTP two-factor authentication, users are required to provide a time-based one-time password (TOTP) called a passcode in addition to their primary credentials. Users also has to install an authenticator application on their mobile devices to generate TOTP passcodes. TOTP passcodes are time-based and valid for one logon attempt only.

- *SMS Two-Factor Authentication*
  Identity Authentication asks two factors to authenticate the user.
  If you set SMS two-factor authentication, users are required to provide an SMS code sent to their mobile devices in addition to their primary credentials.

  > → Remember
  >
  > To use *SMS Two-Factor Authentication*, you must have configured Sinch Verification in the administration console for SAP Cloud Identity Services. For more information, see Configure Sinch Service in Administration Console [page 2051].
  >
  > Users must have their mobile phone numbers verified. The tenant administrator can verify phone numbers manually in the administration console or via the SCIM API. For more information, see List and Edit User Details [page 2361] and Identity Directory API.
  >
  > If the user does not have a verified phone number, the number is verified during the first log on when SMS code is required. After the user provides user name and credentials, he or she should provide the phone number in the field and request a code. Then provide the received code in the respective field and choose *Continue*. If the submitted code is correct, the user is allowed access, and the telephone number is verified.

- *Web Two-Factor Authentication*
  Identity Authentication asks two factors to authenticate the user.
  If you set web two-factor authentication, users are required to authenticate with a device such as the built in biometric scanners or USB, Bluetooth or Near-Field Communication (NFC) devices in addition to their primary credentials.

- *Email OTP Code*
  For security reasons, the Email OTP code is not a recommended two-factor authentication method. You may consider using some of the other methods instead.
  Identity Authentication asks two factors to authenticate the user.
  If you set *Email OTP Code*, users are required to provide the code sent to their email in addition to their primary credentials.

  > → Remember
  >
  > An Email OTP Code template for the respective languages must exist in the tenant to apply the email OTP code method. If the template does not exist, the user will see the option but when choosing it, the following message will appear: "Sorry, but you are currently not authorized for access".
  >
  > For more information how to add email templates, see Edit or Add an Email Template Set [page 2289].

- *RADIUS Server Two Factor Authentication*
  If you set *RADIUS Server Two Factor Authentication*, users are required to provide a RADIUS passcode in addition to their primary credentials. Users must have a RADIUS token (hard or soft) configured for them to generate passcodes. For more information about how to configure

RADIUS server in Identity Authentication, see Configure RADIUS Server Settings (Beta) [page 2192].

The *Action* filed is mandatory.

- *IP Range*
  Define a range of IP addresses that authentication requests to Identity Authentication can be sent from. The value has to be specified in Classless Inter-Domain Routing (CIDR) notation.

  > ### Note
  > By default the field is empty, meaning that any IP is allowed.

  > ### Example
  > Enter 123.45.67.1/24 to allow users to log on from any IP starting with 123.45.67.

  If no IP range is defined, the rule is valid for all IP ranges.
- *Forwarded IP Range*
  Define a range of IP addresses for the original IP addresses that authentication requests to Identity Authentication can be sent from. This range is used in conjunction with IP Range in scenarios where authentication requests to Identity Authentication are made by a proxy on-behalf of the user/client. The value has to be specified in Classless Inter-Domain Routing (CIDR) notation.

  > ### → Remember
  > To specify the *Forwarded IP Range*, the *IP Range* must be defined first.
- *Authentication Method*
  Specify the authenticating method, which the authenticating user has to use. If no method is selected, the rule is valid for any of the methods.
- *User Type*
  Specify the type, which the authenticating user must have. If no user type is selected, the rule is valid for any of the types.
- *Group Type*
  - Cloud Group - A group that is created in the Identity Directory of Cloud Identity services. This is the default choice. For more information about the Identity Directory groups, see Groups [page 514].
  - On-Premise Group - A corporate user store group.
- *Group*

  > ### Restriction
  > The administrator must be assigned the *Manage Groups* role or be part of a policy that allows reading groups to be able to view the groups in the list. For more information, see Edit Administrator Authorizations [page 2309] or Configure Group Authorizations [page 2320].

  Specify a cloud or on-premise group, which the authenticating user has to be a member of. If no group is selected, the rule is valid for all users.
  If the rule is valid for an on-premise group, type in the name of the corporate user store group, for which this rule should be valid.
  The cloud groups have to be configured in the administration console for Identity Authentication. For more information, see Managing Groups [page 2393].

- *Corporate Attribute*
  Specify an attribute from the corporate identity provider (IdP) assertion, based on which the rule action will be applied.
  The rule must include the attribute name and value. It is valid only when the specified name and value are found in the assertion from the corporate IdP.

  > **Note**
  >
  > For this rule, the *Apply Application Configurations* option of *Identity Federation* must be enabled. For more information, see Configure Identity Federation [page 2614].

- *Email Domain*
  Specify a domain for the email of the authenticating user.

The fields *IP Range*, *Forwarded IP Range*, *Group*, *Authentication Method*, and *User Type* are not mandatory, but at least one of them has to be specified.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose *Risk-Based Authentication*.
4. Choose *+ Create*.
5. Fill in the fields on the *Create Rule* window.
6. Choose *+ Create*.

1.7.2.23 Configure Sinch Service in Administration Console

Configure Sinch Service to enable *Phone Verification via SMS* or *SMS Two-Factor Authentication* in the administration console.

Prerequisites

- You have an account in Sinch Verification Service. Once you create a Sinch service account, you receive an email with your account information.
- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Sinch service enables multichannel two-factor authentication (2FA), adding another layer of security to customers' online accounts, beyond their login and password. The service enables you to configure tokens – such as one-time passwords (OTPs), personal identification numbers (PINs), and verification codes – that are tailored to businesses and particular use cases.

For the integration between Identity Authentication and Sinch service, you must provide information in the administration console for SAP Cloud Identity Services. You can have a Sinch Verification configuration. You can clear the fields by choosing the *Remove Configuration* button at the top of the screen.

Provide the following:

Sinch Verification

Configuration	Notes
Application Key	The *Application Key* obtained via Sinch customer dashboard.
Application Secret	The *Application Secret* obtained via Sinch customer dashboard.
Code Timeout	Optional. Request the Sinch Support team to configure this parameter for the client's Sinch account. → Remember Before configuring this property in the administration console for SAP Cloud Identity Services, first request this property to the Sinch Support team.
SMS Text Template	Optional. Request the Sinch Support team to enable this configuration. The SMS text in the configuration must include the `{{CODE}}` placeholder, where Sinch will include the actual code. For example, `"This is your OTP code {{CODE}}!"` → Remember Before configuring this property in the administration console for SAP Cloud Identity Services, first request this property to the Sinch Support team.

→ Remember

It takes 2 minutes for the configuration changes to take place.

To configure the administration console, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Sinch Service Configuration* list item.
4. Choose the *Edit* button.
5. Select *Sinch Verification* and enter the information that is required.
6. Save your entries.

1.7.2.24 Configure RADIUS Server Settings (Beta)

Configure Remote Authentication Dial-In User Service (RADIUS) server settings in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have the `host`, `port`, and `secret` parameters, configured for the RADIUS server which will be used to authenticate users with RADIUS two-factor authentication. You can receive the parameters from the RADIUS server administrator.

Context

> **Note**
>
> This is a beta feature available on Identity Authentication. You as a tenant administrator can request this feature by reporting an incident on SAP Support Portal Home with component `BC-IAM-IDS`.

You can configure more than one RADIUS server in the administration console for SAP Cloud Identity Services to provide backup. Thus, if the first server becomes unavailable, the system sends a request to the next in the list.

> **→ Remember**
>
> It takes 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *External Services*, choose the *RADIUS Server Configuration* list item.
4. Add a server.

   All fields are required.

Parameter	Details
*Host**	Host address of the RADIUS server (used for user authentication).
*Port**	The port number used by the RADIUS server for authentication requests.
*Secret**	A shared secret is used to encrypt the user password. This shared secret also must be defined in the RADIUS server. Paste the secret defined in the RADIUS server into this field.

5. Choose *User Attribute* and *PAP/CHAP* settings.

   These settings are shared between all configured servers.

Parameter	Details
*User Attribute**	Unique attribute for the user. Configure the supported attribute which the RADIUS server is configured to use for authentication. Possible values are: • **`User ID`** • **`Email`** • **`Login Name`**
*PAP / CHAP**	Authentication method for the RADIUS server. Possible values are: • **`PAP`** • **`CHAP`** The default value is **`PAP`**.

6. Save your entries.

   If the operation is successful, you receive the message `Configuration saved`.

   To delete a server, choose the delete icon 🗑 next to the server, and save your changes.

> ⚠ Caution
>
> Make sure to remove the *RADIUS Server Two-Factor Authentication* rule, when you delete the last RADIUS server configuration. If the configuration is missing, the users cannot log on.

Next Steps

Configure an application to require RADIUS PIN code as a second factor apart from the password for user authentication. For more information, Configure Risk-Based Authentication for an Application [page 2007].

Reuse SAP Cloud Identity Services Tenants for Different Customer IDs [page 2222]

1.7.2.25 Configure Mail Server for Application Processes

Configure mail server for the emails sent to the end users in the different application processes.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Identity Authentication uses own mail server for the emails sent to users for the different application processes. For example, when a user makes a registration for an application, he or she receives an activation email from *ias@notifications.sap.com*.

Identity Authentication provides also the possibility to configure custom mail server for the application processes emails.

Apart from the Identity Authentication own mail server, which is the default configuration for the mail server, and the custom mail server, you can also use the Amazon Simple Email Service for the emails sent to users for the different application processes. Thus, you can modify the sender and receiver the email without having custom mail server.

To use the Amazon Simple Email Service with custom domain, you must own the domain. Otherwise, you can use the `accounts.ondemand.com` or `accounts.cloud.sap` domain and just modify the *From* and *Reply to* fields.

For more information, about the emails sent for the different application processes, see Configuring Email Templates [page 2282].

→ Remember

Once the tenant administrator configures the mail server, all emails go through this configuration.

If you have created a custom mail configuration, and after that you create an Amazon Simple Email Service configuration, the custom mail configuration will be deleted. And also, if you have created an Amazon Simple Email Service, and after that you create a custom mail configuration, the Amazon Simple Email Service configuration will be deleted.

To return to the default settings, remove the configuration.

→ Remember

It takes 2 minutes for the configuration changes to take place.

> ⚠ Caution
>
> When you are using the default mail server configuration, and you start sending multiple emails to invalid addresses, the mail server will be disabled by SAP. To start using the default mail server again you must stop the actions that caused the disabling of the mail server and report an incident on SAP Support Portal Home with the `BC-IAM-IDS` component.

To configure the mail server, choose one of the procedures below:

Configure Custom Mail Server [page 2197]
: Configure custom mail server for the emails sent to the end-users in the different application processes.

Configure Amazon Simple Email Service [page 2199]
: Configure mail server for the emails sent to the end users in the different application processes.

1.7.2.25.1 Configure Custom Mail Server

Configure custom mail server for the emails sent to the end-users in the different application processes.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The custom mail server must support SSL (Secure Sockets Layer) and Transport Layer Security 1.2 (TLS). Identity Authentication trusts all certificates from Java SE Runtime Environment 17, therefore the mail server should use only them as a certificate authority when communicating with Identity Authentication. All certificate authorities from the certificate chain must be trusted by Identity Authentication to be able to communicate with the mail server.

> → Tip
>
> You can configure rate limits for your emails between 30 and 600 per minute. Beware that this affects all types of emails, including parallel bulk upload of users.
>
> If a rate limit is not specified, Cloud Identity Services tries to send all emails. You should consider setting the rate limit based on the capabilities of your custom mail server.

> → Remember
>
> You can have only one mail server configuration. Once you configure the custom mail server, all emails will go through this configuration.
>
> To return to the default settings, remove the configuration.

To configure the custom mail server, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *External Services*, choose the *Mail Server Configuration* list item.
4. Choose the *Custom Mail Server* tab.
5. Choose the authentication mechanism, and enter the required information in all the fields.

   > ⓘ Note
   >
   > SAP is not responsible for the information in the fields, and it can't provide technical assistance on the correct values. Please contact your IT Department for the correct custom mail server configurations in the administration console.

   > → Remember
   >
   > The custom mails server host must be reachable over the Internet.
6. Save your entries.

   If the operation is successful, you receive the message `Configuration saved`.

   > → Tip
   >
   > To return to the default settings, remove the configuration.

Example

Testing Mail Server Configuration

Access the profile page at `https://<tenant ID>.accounts.ondemand.com/` from a new browser where you do not have an active session with Identity Authentication. Choose the *Forgot password?* link from the logon page to start the reset password process.

> → Remember
>
> Only three emails are allowed to be sent via Identity Authentication for 24 hour. If you have already reached the limit, the system will not send an email. To check the number of emails sent to the user, access *administration console for SAP Cloud Identity Services* > *Users & Authorizations* > *User Management* > *your user* > *Authentication* > *Password Details*. Next to *Password Reset* you can see the number of emails sent to the user. If necessary, choose *Reset Counter* to be able to send more emails.

If the reset password email is sent successfully, and the configuration is correct, the email that you receive should have as a sender the email specified in the configuration.

If the configuration is not correct, no email is sent.

Task overview: Configure Mail Server for Application Processes [page 2195]

Related Information

Configure Amazon Simple Email Service [page 2199]
Configuring Email Templates [page 2282]

1.7.2.25.2 Configure Amazon Simple Email Service

Configure mail server for the emails sent to the end users in the different application processes.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

By using *Amazon Simple Email Service* you can modify the sender and receiver of the email without the need to have a custom mail server.

To use the Amazon Simple Email Service with custom domain, you must own the domain.

If you don't have an own domain you can use the domain, which is the default one, and just modify the `<username>` part in the *From* and *Reply to* fields. You can add up to two domains in addition to the default one.

Once the tenant administrator configures the mail server, all emails will go through this configuration.

> → Remember
>
> To return to the default settings, remove the configuration.
>
> Note that it takes two minutes for each configuration change to be applied.

To configure the mail server, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *External Services*, choose the *Mail Server Configuration* list item.
4. Choose the *Amazon Simple Email Service* radio-button
5. **Optional:** To use the Amazon Simple Email Service with custom domain, add a valid domain name in the dialog box that appears.
   a. Copy the TXT and CNAME records that are created in the administration console for SAP Cloud Identity Services and enter them in the DNS server.
   b. Choose *Verify* to check the status of the domain in the administration console.

      Domain verification may take up to 72 hours to complete (usually it takes around 5 minutes).

      Status of the domain will change from *Pending* to *Verified* if Amazon has verified the domain, otherwise it will change to *Failed* after 72 hours.

      If you want to start the verification process again, you need to delete the domain and add it again.
6. Configure the <username> parts in the *From* and *Reply to* fields under *Communication Emails*.

   > ⓘ Note
   >
   > The <username> part of the email address can have the following:
   > - uppercase and lowercase Latin letters
   > - digits from 0 to 9
   > - special characters !#$%&'*+-/=?^_`{|}~
   >
   > The <domain> part of the email address can have the following:
   > - uppercase and lowercase Latin letters
   > - digits from 0 to 9
   > - hyphen
   >
   > You can't specify a hyphen at the beginning or end.

   > ⚠ Caution
   >
   > If you have more than one verified domain, make sure that you have selected the correct ones from the drop down in the domain part under *Communication Emails*.
7. Save your entries.

   If the operation is successful, you receive the message `Configuration saved`.

   > → Tip
   >
   > To return to the default settings, remove the configuration.

Example

Testing Mail Server Configuration

Access the profile page at `https://<tenant ID>.accounts.ondemand.com/` from a new browser where you do not have an active session with Identity Authentication. Choose the *Forgot password?* link from the logon page to start the reset password process.

> → Remember
>
> Only three emails are allowed to be sent via Identity Authentication for 24 hour. If you have already reached the limit, the system will not send an email. To check the number of emails sent to the user, access *administration console for SAP Clou Identity Services* > *Users & Authorizations* > *User Management* > *your user* > *Authentication* > *Password Details* . Next to *Password Reset* you can see the number of emails sent to the user. If necessary, choose *Reset Counter* to be able to send more emails.

If the reset password email is sent successfully, and the configuration is correct, the email that you receive should have as a sender the email specified in the configuration.

If the configuration is not correct, no email is sent.

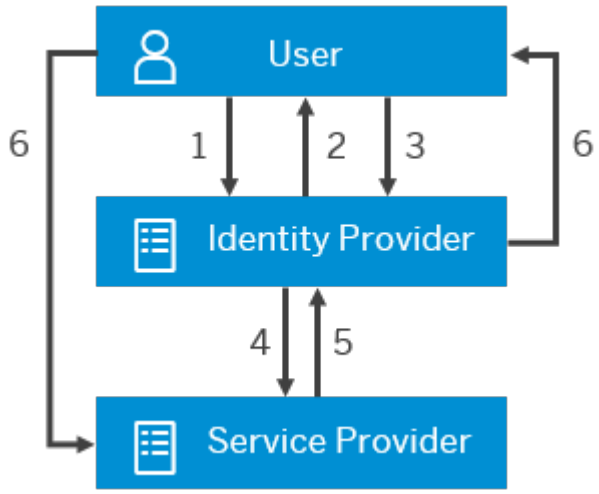
1.7.2.26 Configure IdP-Initiated SSO

Enable or disable IdP-Initiated SSO via the administration console for SAP Cloud Identity Services.

Overview

In the IdP-Initiated Single Sign-On (SSO), the authentication starts at the identity provider (IdP). The user is first authenticated at the identity provider, and after that he or she is allowed to access the protected resource at the application ((service provider (SP)).

> → Remember
>
> IdP-initiated SSO is supported only for SAML 2.0 applications.



1. The user access the identity provider via a link.
2. The identity provider requires credentials.
3. The user provides credentials, and he or she is authenticated.
4. The identity provider sends assertion about the user to the service provider.
5. The service provider validates the assertions and gives access rights to the user.
6. The identity provider redirects the user to the protected resource.

> → Remember
>
> The service provider (SP) metadata that is used to configure the trust must contain the default assertion consumer service (ACS) endpoint that can process unsolicited SAML responses.

> ⓘ Note
>
> When SAP BTP acts as a service provider, the ACS endpoint should be the URL of the protected application resource. To point to the application protected URL, change the ACS endpoint on the identity provider side . For more information about how to change the ACS endpoint in Identity Authentication, see Configure Trust [page 1941].

The link for IdP-Initiated SSO follows the pattern: `https://<tenant_ID>.accounts.ondemand.com/saml2/idp/sso?sp=<sp_name>[&RelayState=<sp_specific_value>&index=<index_number>]`

> ⓘ Note
>
> The following table lists the URL parameters you can use for IdP-initated SSO.

URL Parameters for IdP-Initiated SSO

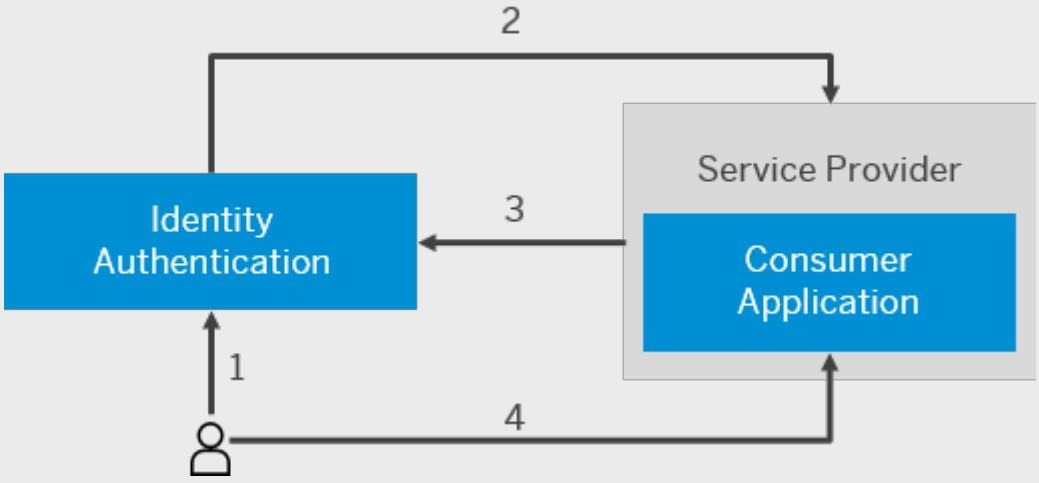
Parameter	Mandatory	Description
`sp`	Yes	Name of the SAML 2 service provider for which SSO is performed. The `sp_name` value of the parameter equals to the `Entity ID` of the service provider. This parameter is needed for Identity Authentication to know which service provider to redirect the user to after successful authentication.
`idp`	No	The technical name of the corporate identity provider as configured in the administration console for SAP Cloud Identity Services. When a chain of identity providers are allowed for an application via conditional authentication, these parameters enable the client to specify which corporate identity providers are to be used. Identity Authentication uses the `idp` parameter to detect the correct corporate identity providers and redirect the request to them. When there is more than one corporate IdP in the IdP-initiated link, they are separated by comma "`,`" without space between them.
`index`	No **Note** You can choose by the index the correct ACS endpoint for unsolicited SAML response processing. Provide the `index` parameter when the default ACS endpoint, which has been configured via the administration console can't process unsolicited SAML responses.	Enter the index number of the endpoint of the assertion consumer service of the service provider as the target of the SAML response. Otherwise, the identity provider uses the default endpoint configured for the trusted service provider. A non-digit value or a value for an index entry that is not configured returns an error message.

Parameter	Mandatory	Description
`login_hint`	No	The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen. Supported values are the allowed logon identifiers for the users. The options are *User ID*, *Login Name*, and *Email* (For SAML 2.0). For more information, see Configure Allowed Logon Identifiers [page 2146] .
`redirect_uri`	No	URI to redirect the user agent to after a web session is created based on the SSO token. Required only if no `sp` parameter is provided. **⚠ Restriction** The URI must be registered in the applications that participate in the SSO flow.
`RelayState`	No	Relay state forwarded to the service provider with the SAML response. **⚠ Restriction** Not supported for the Cloud Foundry environment.

Parameter	Mandatory	Description
`sso_token`		Value of the SSO token, created in the previous OIDC token exchange call, allows reentry into the web context of Identity Authentication, based on the OIDC runtime. **Note** Create the SSO token with a token exchange call using **`resource=urn:sap:identity:sso`** at the token endpoint. For more information, see Configure the Client to Call Identity Authentication Token Exchange [page 2707].

Example

Richard Wilson, tenant administrator at Company A, would like to set up an IdP-initiated SSO process and has configured the default assertion consumer service (ACS) endpoint correctly at the cloud identity provider. Dona Moore, who is an employee at Company A, tries to access the identity provider, but because she does not have a valid session she is prompted to provide credentials. Once Dona has logged in at the IdP, a session is created for her. She is automatically redirected to her application (the default ACS URL as specified in the service provider (SP) metadata)).



1. User provides credentials; logs on.
2. Identity Authentication sends assertions.
3. Service provider validates assertions; gives access rights.
4. User accesses content.

Enable or Disable IdP-Initiated SSO

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have specified the default assertion consumer service (ACS) endpoint in the configuration of a trusted service provider (SP) in the administration console for SAP Cloud Identity Services. For more information, see Configure Trust [page 1941].

Context

By default, IdP-Initiated SSO is enabled in Identity Authentication. The tenant administrator can disable the IdP-Initiated SSO process via the administration console for SAP Cloud Identity Services.

> ⚠ Caution
>
> When IdP-Initiated SSO is disabled, users cannot access their profile page.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

Use this procedure to disable or enable the IdP-Initiated SSO process.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose *Application Resources* > *Tenant Settings*.
3. Under *Single-Sign-On*, choose *IdP-Initiated SSO*.
4. Use the slider under the *Settings* section to disable or enable it.
   If the operation is successful, you receive a confirmation message.

1.7.2.27 Sync SSO Cookie Between Domains

Enable the *Sync SSO Cookie Between Domains Settings* option to allow seamless single sign-on (SSO) and single logout (SLO) across the Cloud Identity Services domains - `ondemand.com` and `cloud.sap`.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- The users have allowed third-party cookies in their browsers.
- The `*.cloud.sap` domain is permitted through your corporate firewall. The `cloud.sap` top-level domain (TLD) is non-standard and may be blocked by default in corporate network configurations. Confirm with your network administrator that traffic to `*.cloud.sap` is allowed before enabling this option.

Context

> ⚠ Restriction
>
> This configuration isn't relevant if you're using a custom domain.

Some applications have trust configurations with the `ondemand.com` domain, while others with the new `cloud.sap` domain. This can cause problems with the SSO and SLO between two application using different domains, and trust configuration in the corporate identity provider (IdP).

> → Remember
>
> Use this option when migrating from `ondemand.com` to `cloud.sap`. The long-term usage of the option isn't recommended.

The *Sync SSO Cookie Between Domains Settings* is disabled by default. To enable it, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Single-Sign On*, choose the *Sync SSO Cookie Between Domains Settings* list item.
4. Use the slider next to the option to enable it.

   > → Remember
   >
   > It takes 2 minutes for the configuration changes to take place.

   If the operation is successful, you see a confirmation message.

1.7.2.28 Send Security Alert Emails

Send security alert emails to end-users or administrators when changes in their accounts are made.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The tenant administrator can configure the system to send security alert emails when some of the following actions are carried out:

- *Email change*
- *Login Name change*
- *Phone change*
- *Credential change*
- *Administrator authorization removal*
- *TFA device activation or deactivation; postpone enabling of Two-Factor Authentication*
- *Registration with nonunique email*

> ⓘ Note
>
> The email user identifier must be selected unique. For more information, see Configure User Identifier Attributes [page 2149].

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

Only the affected user (end-user or administrator) receives the security alert email.

The security alert e-mails are disabled by default. To start sending security alert e-mails, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *General*, choose the *Security Alerting* list item.
4. Use the slider next to an action to enable the sending of security alert emails for it.

   If the operation is successful, you receive a confirmation message.

1.7.2.29 Enable Password Expiration Reminder

Enable password expiration reminder for SAP Cloud Identity Services to ensure the users are aware that a password change is due.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The tenant administrator can configure the system to show a password expiration reminder at the sign-in page of the user. When enabled, the reminder message starts to appear on each sign-in 10 days before the password is due to be changed. The user has the option to change the password immediately or skip the reminder.

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

The password expiration reminder is disabled by default. To enable it, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *General*, choose the *Password Expiration Reminder* list item.
4. Use the slider next to the option to enable it.

   If the operation is successful, you receive a confirmation message.

1.7.2.30 Send System Notifications via Emails

You can configure the administration console to send emails with information about expiring certificates, system notifications, new administrators, and new applications to specific email addresses or to the emails of all administrators.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The tenant administrator can configure the system to send emails to administrators for the following events:

- *Expiring Certificates* - An email is sent 30 days, 14 days, and 3 days before the certificate expires

  > ⚠ Caution
  >
  > The system does not send email notifications for expiring certificates for API authentication. For more information, see Configure Certificates for API Authentication [page 2001].

- *System Notifications* - An email is sent the day after the notification is created. The notifications are created by the SAP Cloud Identity Services team about important updates relevant for everyone.
- *New Administrators* - An email is sent right after the administrator is created
- *New Applications* - An email is sent right after the application is created

> → Remember
>
> It takes 2 minutes for the configuration changes to take place.

> ⓘ Note
>
> With the Jul 5, 2023 upgrade, the first administrator in every new tenant, created after that date, and all newly created administrators are automatically subscribed for system notifications.

To start sending system notifications via emails, proceed as follows:

> ⚠ Caution
>
> When you delete administrators, their emails remain part of the system notifications configuration and they'll continue to receive notifications. To stop sending notifications, remove the emails from the list.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *General*, choose the *System Notifications and Alerts* list item.
4. Choose the *Add* button and select one of the options in the popup that appear:
   - *New email* - enter the email that you want to receive notifications.
   - *All administrators* all tenant administrators will receive the notifications.
5. Confirm your choice by choosing the *Add* button in the pop up.
6. Configure the notifications by selecting the desired check-boxes for each email.

   > ⓘ Note
   >
   > By default all check-boxes are selected.
7. Save your configuration.

   If the operation is successful, you receive a confirmation message.

1.7.2.31 Configure Default Language for End User Screens

Select the language that the end user screen uses if the language of the browser isn't in the list of supported languages.

Context

The end user screens of the applications that use Cloud Identity Services for authentication, support the following languages: Arabic (ar), Bulgarian (bg), Catalan (ca), Chinese PRC (zh_CN), Chinese Taiwan (zh_TW), Croatian (hr), Czech (cs), Danish (da), Dutch (nl), English United Kingdom (en_GB), English United States (en_US), Estonian (et), Finnish (fi), French Standard (fr), French Canada (fr_CA), German Standard (de), Greek (el), Hebrew (iw), Hungarian (hu), Italian (it), Japanese (ja), Korean (ko), Latvian (lv), Lithuanian (lt), Malay (s), Norwegian (no), Polish (pl), Portuguese Portugal (pt), Romanian (ro), Russian (ru), Serbian (sr), Slovak (sk), Slovenian (sl), Spanish Standard (es), Spanish Mexico (es_MX), Swedish (sv), Thai (th), Turkish (tr), Ukrainian (uk), Vietnamese (vi), Welsh (cy).

The language for the end user screens is set according to the following order of priorities:

1. If the locale is set, the end user screen uses the language set there.
   Setting the locale, sets an Identity Authentication cookie. This cookie is used for all the applications in this session that are configured to use Identity Authentication as identity provider.

   > **Note**
   >
   > The locale can be set in either of the following ways:
   >
   > - The locale is communicated to Identity Authentication by adding a locale parameter to *SAP_IDS.js*.
   >
   >   **Source Code**
   >
   >   ```
   >   <script src="https://<tenant ID>.accounts.ondemand.com/ui/resources/
   >   javascripts/SAP_IDS.js?locale=en_GB" />
   >   ```
   > - The locale is communicated to Identity Authentication by a direct `GET` request.
   >
   >   **Source Code**
   >
   >   ```
   >   https://<tenant ID>.accounts.ondemand.com/ui/public/setLocale?locale=DE
   >   ```

2. If the locale is not set, the end user screen uses the language that the user's browser is set to.
   - If the locale is in the list of supported locales, the end user screen uses this locale's configurations.
   - If the locale is not among the supported locales, Identity Authentication looks for configuration from the language part of the locale. For example if there is a request with `en_CA`, as it is not supported, Identity Authentication looks for configurations with `en`.
   - If the language is not in the list of supported languages, the end user screen uses the language set by the tenant administrator. The choice is from the list of the supported languages. If no configuration is done, the end user screen uses *English United States* language, which is the default value.

→ Remember

It takes 2 minutes for the configuration changes to take place.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Customization*, choose the *Tenant Default Values* list item.
4. Select from the drop-down the language that the end user screen to use when the language of the browser is not in the list of supported languages.

   The default language is *English (United States)*.
5. Save your changes.

1.7.2.32 Prompt Users to Explicitly Accept Privacy Policy Document

Enable the privacy policy configuration in SAP Cloud Identity Services to prompt users to accept the privacy policy document. This ensures that users explicitly confirm their understanding of document.

Context

By default, users are not asked explicitly to confirm that they have read and understood the privacy policy of the application when they are activating their account or when the document is updated. Tenant administrator can enable the option to require the users to confirm the acceptance of the document. A checkbox appears at the registration or update, and users confirm that they have read and understood the privacy policy document before they can continue.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Customization*, choose the *Privacy Policy* list item.
4. Enable the slider for *Privacy Policy Configuration*

Results

Users are explicitly prompted to accept the Privacy Policy document during update or registration. A checkbox appears at the update or registration form, and users must confirm that they have read and understood the privacy policy document before they can continue.

Reuse SAP Cloud Identity Services Tenants for Different Customer IDs [page 2222]

1.7.2.33 Configure P-User Next Index

Set the value for the P-user next index.

Context

Every user in Identity Authentication has a `User ID` which is an automatically generated number preceded by the letter P. The first administrator, which is also the first user, receives the number P 000000. The`User ID` of every other user that is created in Identity Authentication is incremented by 1. Thus the second user has a `User ID` P 000001, and so on. When the number reaches P 999999 it is automatically extended and the next number is P 1000000. You can change the P-number index by setting a new number from which the P-number to start. The new value must always be higher than the current one. For example, the User ID of the latest created user is P 000100, which means that the current P-user index is 100. If you want the of the next user to be P 000200,`User ID` then you should make the P-user index 200.

> ⚠ Restriction
>
> Beware, that after the change is saved you won't be able to set the P-number index value to a number lower than the current one.
>
> The P-number index can't be higher than 2147483647.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Customization*, choose the *Tenant Default Values* list item.
4. Enter a number for the *P-user next index*.
5. Save your changes.

Reuse SAP Cloud Identity Services Tenants for Different Customer IDs [page 2222]

1.7.2.34 Reuse SAP Cloud Identity Services Tenants for Different Customer IDs

You as a tenant administrator can reuse an existing tenant for configurations and automated subscriptions.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have a customer ID for the tenant.

Context

Customers that have subsidiaries can reuse existing Identity Authentication tenants for configurations and automated subscriptions in SAP BTP.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *General*, choose the *Tenant Settings and Information* list item.
4. From the drop-down under the *Additional Settings*, choose the customer or customers that will reuse the tenant you are in now for configurations and automated subscriptions.

   The *Customer records* drop-down contains only the customer ID numbers that are assigned to the global ultimate (the most important company within the corporate family).

1.7.3 Configuring Password Policies

Passwords for the authentication of users are subject to certain rules. These rules are defined in the password policy. Identity Authentication provides you with two predefined password policies, in addition to which you can create and configure up to three custom password policies.

You have the following options for a password policy:

- Standard
  (Predefined) Use this option to set special rules for changing, resetting, and locking a password.

  > ### Note
  >
  > This is the default setting. It meets the minimum strength requirements.

- Enterprise
  (Predefined) Use this option to set enhanced password management features. It's stronger than the standard policy, but weaker than the custom one.
- Custom
  (Configurable) Use this option to set the strongest password management features for the password policy. It's the responsibility of the tenant administrator to configure the custom password policy stronger than the standard and enterprise ones.

> → Remember
>
> This option is only possible if you've configured a custom password policy in the administration console for SAP Cloud Identity Services. For more information, see Configure Custom Password Policy [page 2230].

Password Policy Requirements

Requirement	Standard	Enterprise	Custom

Content of password	• Minimum length of 8 characters;
	• Maximum length of 255 characters;
	• Characters from at least three of the following groups:
	  • Lower-case Latin characters (a-z)
	  • Upper-case Latin characters (A-Z)
	  • Base 10 digits (0-9)
	  • Non-alphabetic characters
		• Minimum length of 8 characters;
		• Maximum length of 255 characters;
		• Characters from at least three of the following groups:
		  • Lower-case Latin characters (a-z)
		  • Upper-case Latin characters (A-Z);
		  • Base 10 digits (0-9)
		  • Non-alphabetic characters
			• Minimum length of 8 characters;
			• Maximum length of 255 characters;
			• Characters from between 1 and 4 of the following groups:
			  • Lower-case Latin characters (a-z);
			  • Upper-case Latin characters (A-Z);
			  • Base 10 digits (0-9);
			  • Non-alphabetic characters
			Note
			The default is at least three of the groups.

Session time limit Indicates when the current session expires.	Yes, 12 hours	Yes, 12 hours	Yes, 12 hours
"Remember me" option Indicates whether the browser can store a cookie with the credentials.	Yes	Yes	Yes

Requirement	Standard	Enterprise	Custom
Forgot password deactivation period Indicates the period during which users can initiate the number of forgot password emails specified by the forgot password counter.	Yes, 24 hours	Yes, 24 hours	Yes, 24 hours
Forgot password counter Indicates how many times a user can initiate forgot password emails during the deactivation period. For example, a user can initiate up to 3 forgot password emails within 24 hours.	Yes, 3	Yes, 3	Yes, 3
Minimum password age Shows the minimum lifetime of a password before it can be changed.	Unlimited	Yes, 24 hours	Yes, minimum 1 hour, maximum 48 hours
Maximum failed logon attempts Indicates how many logon attempts are allowed before the user password is locked.	Yes, 5	Yes, 5	Yes, minimum 1, maximum 6, default choice 5

Requirement	Standard	Enterprise	Custom
Password locked period Indicates how long a password is locked for.	Yes, 1 hour	Yes, 1 hour	Yes, minimum 1 hour, maximum *unlimited* **Note** If *unlimited* is set, the password can be unlocked only by the tenant administrator. For more information, see Unlock User Password [page 2380]. **Caution** If *unlimited* is selected, email template set must also be changed. Otherwise, the user will receive an email stating that password logon to the account was disabled for - 1 hour. For more information, see Configuring Email Templates [page 2282].
Maximum password age Shows the maximum lifetime of a password before it has to be changed.	Unlimited	Yes, 6 months	Yes, minimum 1 month, maximum *unlimited* Possible values: 1 month, 2 months, ... 6 months; 1 year, 2 years, 3 years; unlimited
Password history Indicates whether a password history is retained, and how many passwords from the history are retained.	Unlimited	Yes, the last 5 passwords are retained.	Yes, minimum the last 5 passwords, and maximum the last 20 passwords are retained.
Maximum unused period Indicates how long the system retains unused passwords for.	Unlimited	Yes, 6 months	Yes, minimum 1 month, maximum 6 months

Requirement	Standard	Enterprise	Custom
Password behavior Indicates possibility to force the user to reset or change password if the applied password policy requires stronger password than the current one.	Not Applicable	Scenario Based • *Reset password* - If a user hasn't used the password during the set user inactivity period, the system will force a password reset at the first logon after the inactivity period expires. • *Change password* - If a user hasn't changed the password within the password lifetime, the system will force a password change at the first logon after the maximum password age period expires.	Yes, administrator can choose from: • *Reset password* • *Change password*

> **Note**
>
> The non-alphabetic characters are all characters that are not lower-case Latin characters (a-z), upper-case Latin characters (A-Z), or base 10 digits (0-9).

As a tenant administrator, you can do the following:

Set a Password Policy for an Application [page 2228]
: As a tenant administrator, you can set a password policy that matches your application logon requirements.

Configure Custom Password Policy [page 2230]
: Tenant administrators can create and configure a custom password policy for scenarios where Identity Authentication is the authenticating authority.

Delete Custom Password Policy [page 2233]
: As a tenant administrator, you can delete the custom password policy that you have created.

Configure Password Exclude List [page 2234]
: As a tenant administrator, you can create a password exclude list to restrict their usage.

1.7.3.1 Set a Password Policy for an Application

As a tenant administrator, you can set a password policy that matches your application logon requirements.

Context

You can choose from standard, enterprise, and custom password policies. The standard and enterprise password policies are predefined, and you cannot configure them. You can configure only the custom password policy.

The strength of the policies grows from standard to custom.

When a user is authenticated for specific application, or there is already an active session with that application, Identity Authentication checks the application's requirement for password policy and the current user's password policy and always applies the stronger policy. Thus even if the application doesn't require an enterprise password policy if the user has already authenticated in application which requires enterprise password policy then the enterprise password policy rules will be applied even if the user accesses an application that doesn't require it.

→ Tip

To see the configuration of the password policies in the tenant, go to *Password Polices* tile and choose the icon next to the policy you want to view.

To set a password policy for an application, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *POLICIES*, choose *Password Policy*.
6. Select the radio button for the password policy.
7. Save your selection.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

   > **Note**
   >
   > Changes may take up to 2 minutes. Users will then sign in according to the new policy. When the user tries to sign in to the application whose password policy has been updated, he or she is prompted to change the password if the current one does not meet the requirements in the updated password policy.

Configure Custom Password Policy [page 2230]

1.7.3.2 Configure Custom Password Policy

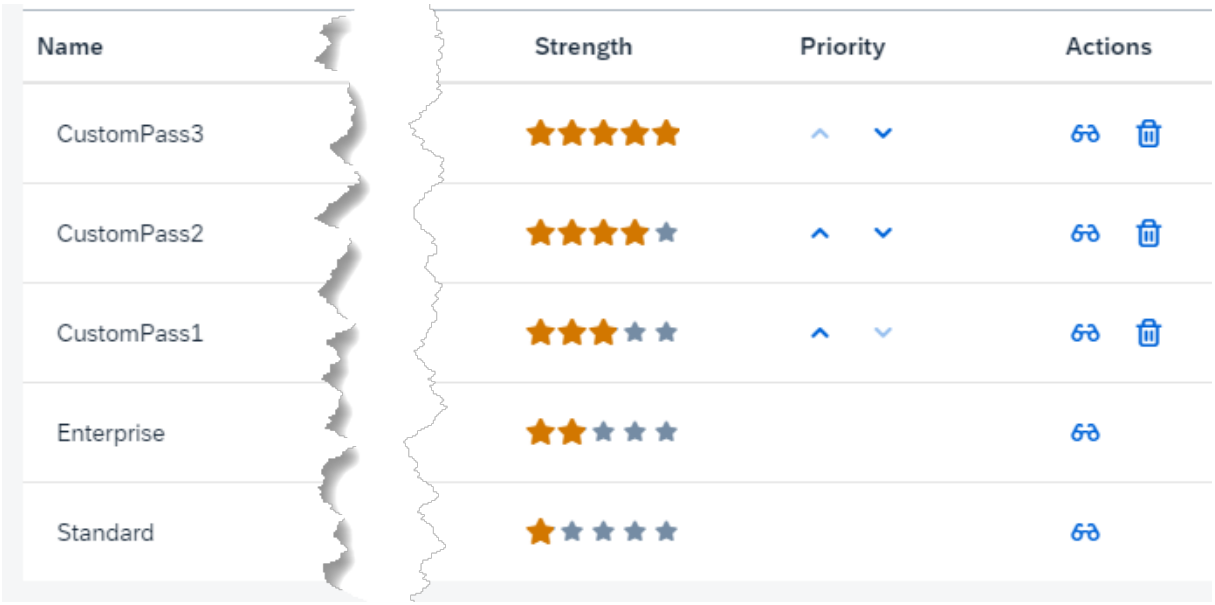
Tenant administrators can create and configure a custom password policy for scenarios where Identity Authentication is the authenticating authority.

Context

Identity Authentication provides you with two predefined password policies, in addition to which you can create and configure up to three custom ones.

The custom password policy by default must be stronger than the enterprise policy, which in turn is stronger than the standard policy. It's the responsibility of the tenant administrator to configure the custom password policy stronger than the standard and enterprise ones. Each password policy has a strength assigned to it, which is visualized by stars in the administration console for SAP Cloud Identity Services. The strength specifies the priority of the password policy. It will define which policy will be enforced for password checks.

It is not possible to have password policies with one and the same strength. Once created and saved, the tenant administrator can reorder the custom password policies in the administration console, thus changing the strength assigned to the custom password policies.



→ Remember

To change the configuration of the custom password policies or to create a new password policy when you have already reached the limit of three custom password policy in the tenant, delete an existing custom policy first, then create the new one. For more information, see Delete Custom Password Policy [page 2233].

Example

Donna Moore is an administrator of company A. She has set a *Standard* password policy for the *Leave Request* application.

Dona Moore wants a stronger password policy for the administration console, and she configured a custom password policy with a minimum password length of 15 characters, and maximum password lifetime of three months. The number of allowed logon attempts is 3. Dona has set a strength of three stars for this password policy.

Dona has set the new custom password policy for the administration console. At his first logon after the setting of the new password policy, Michael Adams, who is also an administrator at Company A, is required to update his password according to the new policy. Thus when he accesses the *Leave Request* application he uses the stronger password. John Miller who is an employee at company A, but not an admin, logs on to the *Leave Request* with a password that is compliant to the *Standard* password policy.

To create and configure a new custom password policy, follow the procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Password Policies* tile.
3. Under *Password Policies*, choose the *+ Create* button.

   > ⚠ Restriction
   >
   > You can create only one custom password policy. If you already have a custom password policy in your tenant, the *+ Create* button is grayed out.

4. Fill in the required information in the fields.

Configuration Options	Information
Policy Name	The name of the password policy that appears in the administration console.
Policy Strength	This strength specifies the priority of the password policy. It will define which policy will be enforced for password checks. It's the responsibility of the tenant administrator to configure the custom password policy stronger than the standard and enterprise ones.
Password Length	The length can be between 8 and 255 characters. The default value is 8 characters.
Password Lifetime	The minimum password lifetime can be between 1 hour and 48 hours. The default value is 24 hours. Possible values are 1 hour, 2 hours, ..., 48 hours. The maximum password lifetime can be between 1 month and unlimited. The default value is 6 months. Possible values are: 1 month, 2 months, ... 6 months; 1 year, 2 years, 3 years; unlimited.

Configuration Options	Information
	Note The *Password Lifetime* configuration for a user starts after the following is done: 1. Create a custom password policy with *Password Lifetime* lifetime configured. 2. Assign the password policy to an application. 3. Authenticate to the application so the policy is assigned.
User Inactivity	The maximum duration of user inactivity can be between 1 and 6 months. The default value is 6 months. **Note** If a user didn't use the password during the set user inactivity period, the system will force either a password reset or change at the first logon. The reset or change depends on the setting for *Password Behavior*.
Password History	The minimum requirement is the last 5 passwords to be retained. The value can't be more than 20.
Failed Sign In Attempts	The number of allowed failed sign in attempts can be between 1 and 6. The default value is 5.
Password Locked Period	The period can be between 1 hour and unlimited. **Tip** When *Unlimited* is selected, we recommend you to mark this password policy the strongest.
Required Character Groups	Specifies the number of required character groups for the password. The value can be between 1 and 4. Based on the value, the users are required to include 1, 2, 3 or 4 of the following in their passwords: • Uppercase letters • Lowercase letters • Numbers • Symbols
Password Behavior	• *Reset password* - At logon, the user is forced to reset password, if the current password is not compliant with the new password policy. This is the default choice. • *Change password* - At logon, the user is redirected to the change password page if the current password is not compliant with the new password policy.

5. Choose + *Create* to save your changes.

   Once the password policy has been created and configured, the system displays the message `Password policies configuration updated`.

The new custom password policy appears in the list of the password policies that you can use for the applications.

Next Steps

To use the custom password policy for your application or applications, you should set it as a password policy for that application or applications. For more information, see Set a Password Policy for an Application [page 2228].

Task overview: Configuring Password Policies [page 2223]

Related Information

Set a Password Policy for an Application [page 2228]
Delete Custom Password Policy [page 2233]
Configure Password Exclude List [page 2234]

1.7.3.3 Delete Custom Password Policy

As a tenant administrator, you can delete the custom password policy that you have created.

Prerequisites

- You have created a custom password policy in the administration console for SAP Cloud Identity Services. For more information, see Configure Custom Password Policy [page 2230].
- The custom password policy should not be set as a password policy for any of the applications in the tenant. For more information about how to set a standard or enterprise policy for an application, see Set a Password Policy for an Application [page 2228].

Context

You can only have one custom password policy for your tenant. To change the configuration of the custom password policy, or to create a new one, delete the existing custom policy first.

To delete the custom password policy, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Password Policies* tile.
3. Press the next to the custom password policy.

> ⚠ Caution
>
> You can only delete the password policy if it is not set as a password policy for any applications in the tenant.

Results

Once the password policy has been deleted, the system displays the message `Password policy <name of policy> deleted`.

Task overview: Configuring Password Policies [page 2223]

Related Information

Set a Password Policy for an Application [page 2228]
Configure Custom Password Policy [page 2230]
Configure Password Exclude List [page 2234]

1.7.3.4 Configure Password Exclude List

As a tenant administrator, you can create a password exclude list to restrict their usage.

Context

The exclude list can include *first name*, *last name* and *login name*, and passwords entered as free text.

You can enter up to 1000 passwords in the list. Each password can be up to 256 characters long.

→ Remember

All new passwords cannot contain configured strings. The restriction is case insensitive. For example, the *qwer* string will exclude passwords like "Qwer&Dfdstg", "TestPasswordqwer", etc.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Exclude Lists* tile.
3. Choose the *Password* tab.
4. **Optional:** Under *Dynamic Passwords*, enable the switch next to the options that you want to restrict:

Option	Description
First Name	The password must not include the user's first name.
Last Name	The password must not include the user's last name.
Login Name	The password must not include the user's login name.

5. **Optional:** Under *Password Exclude List* , choose *Create* and enter the password exclude terms as free text in the field.

   For multiple values, use comma between them.
6. Confirm your changes by choosing *Create*.

Delete Custom Password Policy [page 2233]

1.7.4 Configuring Privacy Policies

You can configure a custom privacy policy document by creating a new document, adding and editing its language versions, and defining the document for an application.

Every time you want to update the privacy policy document you add a new language versions for the document.

Each privacy policy document can have one draft and one active version. You can view all language version in the administration console. Optionally you can edit the draft version of a document before making it an active version.

Once a privacy policy document is created it can't be renamed.

For each language version, you have to upload a text file. You can define a privacy policy document in the following languages:

Arabic, Azerbaijani, Bulgarian, Catalan, Chinese (PRC), Chinese (Taiwan), Croatian, Czech, Danish, Dutch, English (United Kingdom), English (United States), Estonian, Finnish, French (Standard), French (Canada), German (Standard), Greek, Hebrew, Hungarian, Italian, Japanese, Korean, Latvian, Malay, Norwegian, Polish, Portuguese (Portugal), Romanian, Russian, Serbian, Slovak, Slovenian, Spanish (Standard), Spanish (Mexico), Swedish, Thai, Turkish, Ukrainian, Vietnamese, Welsh.

The language is defined in the following order of importance:

- By the `locale` parameter in the URL used for accessing the application.

  > **Note**
  >
  > If the SP is configured to support a specific language, only this language is used by the application.

- By the language of the application's browser.

  > **Note**
  >
  > The application takes the browser language only if the SP's language is not selected, and the `locale` parameter isn't set in the URL. The default browser setting is *English*.

> **Note**
>
> If there is only one language for the document, it is recommended to be *English (United States)*.
>
> If the languages are more than one, one of them must be *English (United States)*.

To configure privacy policy in the administration console, do the following:

1. Create a New Privacy Policy Document [page 2237]
   Create a new privacy policy document in the administration console.
2. Add New Language of a Privacy Policy Document [page 2238]
   To add a language version of a privacy policy document, you must upload a UTF-8 encoded plain text file containing the privacy policy text.
3. Add New Version of a Privacy Policy Document [page 2239]
   Add a new version of a privacy policy document and make it active.
4. Define a Privacy Policy Document for an Application [page 2240]
5. (Optional) View and Edit a Privacy Policy Document [page 2241]
   Tenant administrators can view privacy policy documents uploaded in the administration console for SAP Cloud Identity Services and optionally edit the draft versions of those documents.
6. (Optional) Delete a Privacy Policy Document [page 2243]
   Delete a privacy policy document set or a version of a privacy policy document.

1.7.4.1 Create a New Privacy Policy Document

Create a new privacy policy document in the administration console.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Application & Resources*, choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.
3. Choose the *+Add* button on the left-hand panel in order to add a new privacy policy document to the list.
4. Specify a name for the document.

   > ⓘ Note
   >
   > The name can contain only Latin letters, numbers or the underscore character, or a combination of them. The lowercase letters are converted to uppercase letters.
5. Save your selection

   Once the document has been created, the system displays the message `Privacy policy document <name of document> created`.

Task overview: Configuring Privacy Policies [page 2235]

Next task: Add New Language of a Privacy Policy Document [page 2238]

1.7.4.2 Add New Language of a Privacy Policy Document

To add a language version of a privacy policy document, you must upload a UTF-8 encoded plain text file containing the privacy policy text.

Prerequisites

You have created a privacy policy document in the administration console. For more information, see Create a New Privacy Policy Document [page 2237] .

Context

You can add one or more languages of the document.

> ⓘ Note
>
> If there is only one language for the document, it is recommended to be *English (United States)*.
>
> If the languages are more than one, one of them must be *English (United States)*.

The plain text document can include the following tags: `<a>`, `<strong>`, and `<em>`.

> ✤ Example
>
> - `See <a href="https://www.example.com">Subscription conditions</a>`
> - `<strong>Additional requirements</strong>`
> - `<em>Important:</em>`

To open the link from the document in the preview in the admin console, right-click the link and open it in a new tab.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.

3. To add a language to a privacy policy document, choose that document from the list on the left.

> → Tip
>
> Type the name of the document in the search field to filter the list items.

4. Choose the *Add* button in the details view on the top right-hand corner.
   a. Choose the *Active Language Version* radio button.
   b. Select the language from the drop-down.
   c. Specify the plain text file for the language.

   > ⓘ Note
   >
   > Use a file with an extension `.txt`.

   d. Choose *Add* to save your selection

      Once the file has been uploaded, the system displays the message `Privacy policy file uploaded`.

Task overview: Configuring Privacy Policies [page 2235]

Previous task: Create a New Privacy Policy Document [page 2237]

Next task: Add New Version of a Privacy Policy Document [page 2239]

1.7.4.3 Add New Version of a Privacy Policy Document

Add a new version of a privacy policy document and make it active.

Context

To update an existing privacy policy document you must add a new version for each language of this document by uploading a UTF-8 encoded plain text file containing the updated privacy policy statement. Once the new version is uploaded it is in a status draft. You must activate it to replace the current active version. To make a draft version active, you must have draft versions for all the languages that the current active version has.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.

3. To add a new language version to a privacy policy document, choose that document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.

4. Choose the *Add* button in the details view on the top right-hand corner.
   a. Choose the *Draft Language Version* radio button.
   b. Select the language from the drop-down for that version.
   c. Specify the plain text file for the language.

      > ⓘ Note
      >
      > Use a file with an extension `.txt`.

   d. Choose *Add* to save your selection

      Once the file has been uploaded, the system displays the message `Privacy policy file uploaded`.
5. Repeat the procedure for all languages that have active versions.
6. **Optional:** To make the draft version active, choose *Activate* in the details view on the top right-hand corner.

Task overview: Configuring Privacy Policies [page 2235]

Previous task: Add New Language of a Privacy Policy Document [page 2238]

Next task: Define a Privacy Policy Document for an Application [page 2240]

1.7.4.4 Define a Privacy Policy Document for an Application

Context

The privacy policy is displayed on the registration form, which form appears when the user chooses the *Register Now* link on the logon page. It is also shown to the user when the registration information has been upgraded. Initially, the application is set to use a default privacy policy on the registration and upgrade forms. To change this configuration, you have to select a custom privacy policy.

If you have the authorization, you can create a custom privacy policy document. This document is used once you have set it for the respective application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *POLICIES*, choose *Privacy Policy*.
6. Select the radio button for the Privacy Policy.
7. Save your selection.

Task overview: Configuring Privacy Policies [page 2235]

Previous task: Add New Version of a Privacy Policy Document [page 2239]

Next task: (Optional) View and Edit a Privacy Policy Document [page 2241]

1.7.4.5 (Optional) View and Edit a Privacy Policy Document

Tenant administrators can view privacy policy documents uploaded in the administration console for SAP Cloud Identity Services and optionally edit the draft versions of those documents.

Context

The content of the privacy policy documents are visualised in the administration console.

Task overview: Configuring Privacy Policies [page 2235]

Previous task: Define a Privacy Policy Document for an Application [page 2240]

Next task: (Optional) Delete a Privacy Policy Document [page 2243]

View a Privacy Policy Document

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.
3. Choose the document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose the version and language from the drop down.

   The content is displayed on the screen.

   To view another privacy policy document, repeat the procedure.

Edit a Draft Version

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.
3. Choose the document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose the draft version from the drop down.
5. Choose a language for the draft version from the drop down.
6. Choose *Edit* in the details view on the top right-hand corner.
7. Upload the edited document.
8. Choose *Edit* in the popup to confirm your changes.

1.7.4.6 (Optional) Delete a Privacy Policy Document

Delete a privacy policy document set or a version of a privacy policy document.

Context

You can delete a specific language version or the entire set of privacy policy documents. Deleting the entire set of privacy policy documents, you delete all language versions for this set. The privacy policy document set is removed from the list of the privacy policy documents in the administration console for SAP Cloud Identity Services, when you delete it.

The documents will be deleted no matter if they are accepted or not by any users.

> ⓘ Note
>
> You can delete only documents that are not defined for applications. To delete a document version or entire document set that is defined for an application, you first you must set another privacy policy for the applications. For more information, see Define a Privacy Policy Document for an Application [page 2240].

To delete a privacy policy document set or a specific language version, follow the procedure below:

Task overview: Configuring Privacy Policies [page 2235]

Previous task: (Optional) View and Edit a Privacy Policy Document [page 2241]

Delete Entire Documents Set

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.
3. To delete the entire privacy policy document set, choose that set from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose *Delete Set* button and confirm the operation in the pop-up that appears.

   If a document is defined for an application, define a new privacy policy document for that application and repeat the step.

   If the document set is deleted, the system displays the message `Privacy Policy document set deleted`.

Delete a Language Version

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Privacy Policy Documents* tile.

   This operation opens a list of the privacy policy documents.
3. To delete a language version to a privacy policy document, choose that document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.

   a. Select the version from the drop-down that you want to delete.
   b. Select the language from the drop-down for that version that you want to delete.
   c. Choose *Delete* button and confirm the operation in the pop-up that appears.

      If the document is defined for an application, define a new privacy policy document for that application and repeat the step.

   If the document version is deleted, the system displays the message `Privacy Policy document deleted`.

1.7.5 Configuring Authorization Policies

Authorization Management enables SAP Cloud Identity Services administrators to use authorization policies, customize them, and assign them to users.

When you subscribe to an application that supports authorization policies, you get a corresponding application in *Applications*, and from there you can assign authorizations.

For more information, see Subscribe to Multitenant Applications Using the Cockpit, Assign Authorization Policies [page 2363], and Add Users to a Group [page 2406].

Prerequisites

- Your application supports authorization policies. Refer to the documentation of your application.
- Your user has administrative permissions in SAP Cloud Identity Services with the following authorizations:
  - *Manage Applications*
  - *Manage Groups*
  - *Read Users*

  For more information, see Edit Administrator Authorizations [page 2309].
- You are using SAP Cloud Identity Services - Identity Authentication. For more information, see Tenants [page 27].

> **Note**
>
> If your application doesn't have an *Authorization Policies* tab, it doesn't support Authorization Management.

Authorization Management

Authorization Management allows SAP Cloud Identity Services administrators to refine authorization policies based on application policy templates with powerful instance restrictions for data access. Developers define and deploy authorization policies with functional checks, instance-based authorizations, and user attributes. They're available in the SAP Cloud Identity Services administration console. If necessary, developers can update existing authorization policies.

For more information, see Developing Authorizations [page 2876].

Authorization Policy Types

An authorization policy is basically a collection of rules, which are applied to resources and restricted by conditions. Authorization policies are defined by developers and come with the respective application.

Setting Up Authorization Policies

Task	User Role	Tool
Define authorization policies	Developer	Development environment
Deploy authorization policies with the application	Developer	Development environment
Modify authorization policies	Administrator	Administration console
Assign authorization policies to users	Administrator	Administration console
Delete authorization policies	Administrator	Administration console

We distinguish between different types of authorization policies. You recognize the different types in the *Package* column.

- The package name of the base policies is defined by the application.
- Customers can deploy their own authorization policies in customer-developed packages, which have the package name *Customer Package* in the list of authorization policies.

Authorization Policy Types

Type	Description
Base authorization policy	Authorization policy delivered by the application. Administrators can copy the authorization policy and modify the copy. The copy, modified or not, is a custom authorization policy. You can't change or delete it in the administration console.
Custom authorization policy	Authorization policy created by administrators. You can change and delete this authorization policy in the administration console.

> ⚠ Restriction
>
> To make sure that Authorization Management is resilient, we've introduced an upper limit of 200 custom authorization policies and 200 base authorization policies that can be defined per application.

Configuration Options

Authorization policy administrators can configure the following in custom authorization policies:

- Combine authorization policies. See Combine Authorization Policies [page 2249].
- Add or delete rules and restrictions and their attribute values. See Edit an Authorization Policy [page 2248].

Refining Authorization Policies

Administrators can edit an existing custom authorization policy. They can add restrictions and manage the values of the restrictions. The restrictions are refined by attributes with fixed values or user attributes. They can also add USE rules to a custom authorization policy and restrict them.

For more information, see Data Control Language (DCL) [page 2251].

1.7.5.1 Create an Authorization Policy

Identity Authentication administrators can use existing authorization policies to create an authorization policy, configure rules, and assign the authorization policies to users.

Context

You have the following options:

- Create an authorization policy based on the rules of other authorization policies, add restrictions, or change the attribute.
- Create an authorization policy by combining authorization policies.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Choose an application that supports Authorization Management. For information, see the documentation of the application.

   The details page of your application has an *Authorization Policies* tab.
4. Choose the *Authorization Policies* tab.
5. Choose *Create*.
6. Choose one of the following options:

   - *Create Restriction* Create an authorization policy based on base policies, edit rules, add restrictions, statements, and attributes or only change attributes. See Edit an Authorization Policy [page 2248].

- *Add Combination* Create one authorization policy with an OR combination of the rules of two authorization policies. See Combine Authorization Policies [page 2249].

You can now continue by giving the authorization policy a name, choosing the base policies, assigning it to a user or changing its rule.

1.7.5.2 Edit an Authorization Policy

If SAP Cloud Identity Services administrators want to change restrictions and their attributes, they can edit an existing custom authorization policy.

Context

When you edit an existing custom authorization policy, you can add or delete restrictions and their attribute values. You can also assign users to the authorization policy.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Choose the application that supports Authorization Management. For more information, see the documentation of the application.

   The details page of your application has an *Authorization Policies* tab.
4. Choose the *Authorization Policies* tab and select a custom authorization policy. Custom authorization policies appear as *Editable* in the *Editable* column of the list of authorization policies. If the policy contains editable restrictions, it is also marked as *Restricted Editing*.
5. Choose the *Edit* button.

   - (Optional) To assign users, choose the *Assignments* tab. See Assign Authorization Policies [page 2363].
   - The rule that came with the custom authorization policy appears in the *Rules* tab.
6. (Optional) You can enter a label and a description of the authorization policy or change them. The description is an optional comment.
7. To edit the rules of the authorization policy, choose the *Rules* tab.
8. Continue to edit the rules. Multiple options are available.

   - Choose + to see the possible `RESTRICT` options. This button is either directly below `RESTRICT` or in an indented row below `RESTRICT`.
   - Choose *Add USE* to add a `USE` statement to the selected authorization policy. Select a `USE` statement from the available authorization policies.

9. For a `RESTRICT` condition, choose one of the available attributes, an operation, and enter a value. You can choose a value from the value help or type it in. To add another `RESTRICT` condition, choose + or use the `Return` key.

   > **Note**
   >
   > All indented rows that appear in a list directly below `RESTRICT` or `USE` have an `AND` conjunction.
   >
   > All rows starting with their own `RESTRICT` condition have an `OR` conjunction with the other `RESTRICT` rows.

   For more information, see Data Control Language (DCL) [page 2251].
10. Choose the conditions that come with the application in the dropdown list. Next, choose an operator and choose or enter a value or choose a user attribute variable such as *$user.country*. In this case, the value is taken from the user attribute.
11. Save your changes.
12. To assign users, choose the *Assignments* tab. See Assign Authorization Policies [page 2363].

1.7.5.3 Combine Authorization Policies

You can combine authorization policies to create a new one. This new authorization policy gets all the rules of the authorization policies that you combined.

Context

> **Note**
>
> When you combine authorization policies, the new authorization policy has no user assignments.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Choose the *Authorization Policies* tab.
4. Choose *Create*.
5. Choose *Add Combination*.
6. Search for the authorization policies you want to combine, choose them, and enter a name for the new authorization policy.
7. Choose *Confirm*.
8. Select the newly created authorization policy.

9. Choose the *Assignments* tab and assign users. See Assign Authorization Policies [page 2363].
10. Choose the *Rules* tab and edit the label and description of the authorization policy. The description is an optional comment.
11. To change the rules, choose *Edit*. For more information, see Edit an Authorization Policy [page 2248].
12. Save your changes.

1.7.5.4 Delete an Authorization Policy

Identity Authentication administrators can delete an existing custom authorization policy.

Context

> ⚠ Caution
>
> When you delete an authorization policy, remember that you are also removing the user assignments. This means that the users assigned to a deleted authorization policy can't access the application anymore.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Choose an application that supports Authorization Management. For information, see the documentation of the application.

   The details page of your application has an *Authorization Policies* tab.
4. Choose the *Authorization Policies* tab.
5. Choose the custom authorization policy you want to delete.
6. To delete the authorization policy, choose *Delete* and confirm that you want to delete the authorization policy.

1.7.5.5 Data Control Language (DCL)

Developers define authorization policies in SAP Cloud Identity Services. They use an SQL-like language - the data control language (DCL). Administrators can restrict base policies and combine authorization policies into a new authorization policy.

Prerequisites

- Authorization Management is part of the Identity service. You can activate Authorization Management for all applications that are created in SAP Cloud Identity Services.

Policy Definition in DCL

Using this language, developers define authorizations. Administrators can refine them by combining rules in authorization policies created by them. In the administration console, they assign the authorization policies to users.

This is what a policy definition looks like.

> ⓘ Note
>
> Choose the links in the sample code. They take you to a description of the DCL elements.

> {·} Sample Code

```
{
SCHEMA {
    SalesOrderType: number
}
POLICY readSalesOrders_Type {
    GRANT read ON salesOrders WHERE SalesOrderType BETWEEN 100 AND 500;
}
}
```

Structure of the Data Control Language (DCL) [page 2252]
Use DCL syntax to define authorization policies, including rules, actions, resources, conditions, attributes, and a schema. They are essential for controlling access to data and resources.

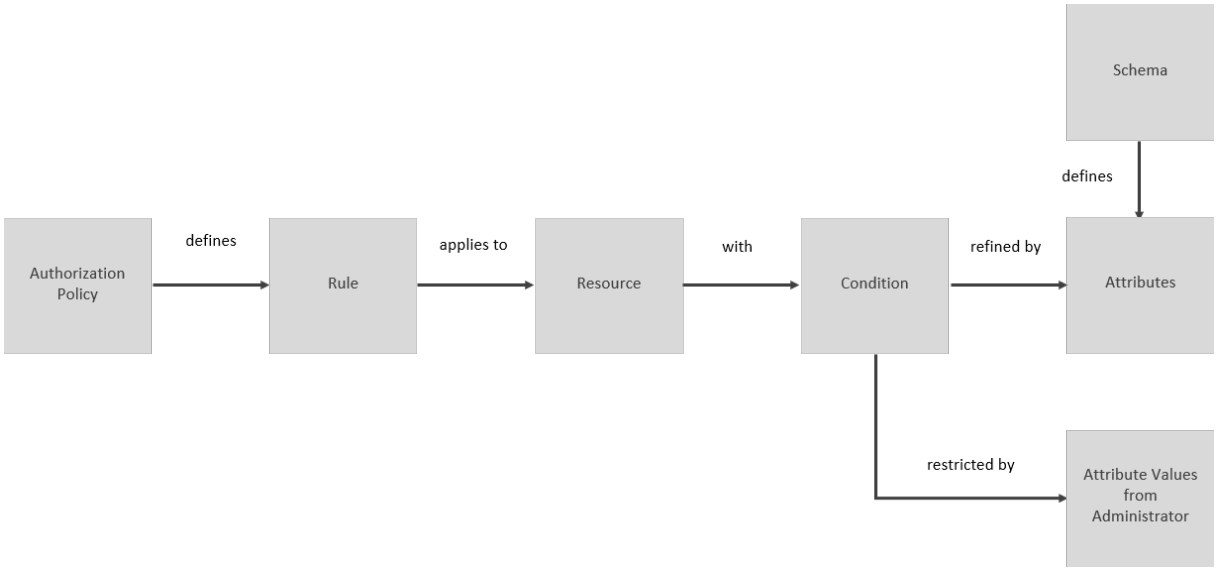
Grammar and Syntax Rules [page 2261]
DCL has a set of grammar and syntax rules you must observe when you define authorization policies.

Advanced Features [page 2269]
You find advanced configuration techniques for authorization policies, focusing on annotations, formatting conventions, and internal functions for enterprise-grade authorization policies.

1.7.5.5.1 Structure of the Data Control Language (DCL)

Use DCL syntax to define authorization policies, including rules, actions, resources, conditions, attributes, and a schema. They are essential for controlling access to data and resources.

The data control language uses the following syntax for the definition of simple and instance-based authorizations.



Authorization Policy

Collection of rules. Administrators can use base authorization policies to create custom authorization policies, change the rules, and assign the policies to users.

Rule

Grants actions such as `read` or `write`. Rules handle actions on resources on resources such as `resource1` or `resource2`. A rule can also be restricted in multiple ways.

An action is granted on a resource. Use the following syntax:

```
GRANT <action> ON <resource> ;
```

- {·} Sample Code

  ```
  GRANT read ON * ;
  ```

Resource

Entities protected by the rule or authorization policy. The application that provides the authorization policy defines the resource. Examples for resources are a data object or an endpoint. A resource has arbitrary attributes that can be used to refine rules.

Condition

A logical expression that is mainly used for filtering. It can be based on attributes with a name and a data type. Before allowing a granted action on a specific entity of a resource, the condition is evaluated with the attribute values of that entity. A condition is a Boolean function over attributes.

```
WHERE <attribute_name> = '<attribute_value>' ;
```

- Sample Code

  ```
  WHERE Country IN ('USA', 'Germany');
  ```

For more information, see Condition Operators [page 2265].

Attribute

You can restrict authorization policies by using a set of conditions with attributes and attribute values. Attributes are defined in a schema or they're provided by an external source, for example an identity provider. When using attributes, you must take care that you declare their data type in a schema. All schema attributes usages are validated to refer to existing names and their usage types.

For more information, see Attribute Constraints [page 2268].

Schema

A schema defines names and types of attributes you want to use for the application. Only one schema can be defined. Define the schema using a file named `schema.dcl` and locate it in the root folder. All schema attributes usages are validated to refer to existing names and their types.

For more information, see Schema Definition [page 2255].

Package

The name of the root folder where the DCL files are located. The package content comprises all of the DCL files in the folder.

For more information, see Package Definition [page 2254].

Parent topic: Data Control Language (DCL) [page 2251]

Related Information

Grammar and Syntax Rules [page 2261]
Advanced Features [page 2269]

1.7.5.5.1.1 Package Definition

A package is the folder where the DCL document is located.

A package can contain multiple DCL documents.

> ⚠ Restriction
>
> - Only `[a-zA-Z_][a-zA-Z_0-9]*` can be used for a package name, which is the name of the path relative to the DCL root.
> - The total length (including package separator) of a package hierarchy is 250 characters.

Cross Package Reuse

Policies from other packages can be reused based on qualified references.

References

Qualified references are used to specify elements across package boundaries. The parts of a qualified reference are connected by a "`.`" (period) in DCL.

Examples

- `sales.SalesOrder:` Package `sales`, Policy: `salesOrder`
- `sales.basic.salesOrder`: Package `sales/basic`, Policy: `salesOrder`

You can introduce qualified references in a compatible way with an additional qualification prefix.

> {·} Sample Code

```
POLICY <policy_name1> {
    USE <package>.<policy_name2>; // <policy_name2> is qualified by <package>
    USE <policy_name3>;           // local policy (same package)
```

```
}
```

- Sample Code

```
POLICY allAdmins {
    USE sales.salesOrders; // fully qualified name to 'salesOrders' in
package 'sales'
    USE readAll;           // local policy
}
```

1.7.5.5.1.2 Schema Definition

A schema defines attribute names and data types that can be used when defining an authorization policy.

To describe the names and types of attributes, you define a schema. You must define a schema in a file called `schema.dcl`. It must be located in the DCL root folder. If attributes are defined in the schema, you can use the grammar element `WHERE` with these attributes. All usages of schema attributes are validated to refer to existing names and that their usage context complies with the respective data types.

Output Code

```
├─ <application>
└─ ams-policies-deployer
    ├─ package.json
    └─ dcl
        ├─ sales
        │  └─ policy_a.dcl
        │  └─ policy_b.dcl
        └─ schema.dcl
```

Attributes in the schema can be used in the `WHERE` grammar element. The usage of all attributes are validated to make sure that they refer to existing names and that their usage context complies with their type.

```
SCHEMA {
    <attribute>: <data_type>
}
```

Data types for attribute values include String, Number, Boolean, and Structure, with options for arrays.

Use the following data types:

- String, String[]
- Number, Number[]
- Boolean, Boolean[]
- Structured type

You can also assign a special null value to an attribute.

A structured type allows specifying hierarchical types.

- The following schema contains an attribute with the data type "number" and an attribute name with the data type "string".

Sample Code

```
SCHEMA {
    salesID: Number,
    Country: String
}
```

- The schema must always define all data types of the attribute values. In the following example code, `Sales` is a structure that groups different attributes related to `Sales`.

Sample Code

```
SCHEMA {
     Sales: {
       Country: String,
       SalesID: Number}
 }
```

There is a predefined default `$user` structure that is populated by the client libraries with OIDC token content in a standard setup.

Sample Code

```
SCHEMA {
    ...
    $user: { // Default $user definition. This is injected if no custom $user
definition is present
        user_uuid: String,
        scim_id: String,
        groups: String[],
        email: String
    }
```

The `$user` structure can be extended with custom attributes.

Related Information

Formats [page 2270]

1.7.5.5.1.3 Authorization Policy Definition

You can grant basic actions like `read` or `write` on resources with an SQL-like syntax. The authorizations are grouped under an authorization policy. You can also combine authorization policies.

You define basic actions in applications. Application developers must make sure that the applications query the actions and resources that are defined in the DCL files. Applications can use actions and resources in the code for authorization checks.

The syntax of an authorization for granting actions looks like this:

```
POLICY <policy_name> {
    GRANT <action> ON <resource> ;
}
```

Examples

- A simple policy that enables the user to perform a `read` action on all resources.

  Sample Code

  ```
  POLICY readAll {
      GRANT read ON * ;
  }
  ```

- A simple policy that enables the user to perform `read` and `write` actions on all resources.

  Sample Code

  ```
  POLICY readAndWriteAll {
      GRANT read, write ON * ;
  }
  ```

- A simple policy, which restricts all resources only on defined attribute values without any action. Use the `WHERE` condition to refer to attributes.

  Sample Code

  ```
  POLICY CountryCode {
      GRANT * ON * WHERE Country = 'US' OR Country = 'DE';
  }
  ```

- A rule that allows the user to do action `read` on all resources with an special attribute value. Use `WHERE` to implement a condition that restricts a `read` action on resources by attributes. You can also use multiple conditions on resources, for example according to a list of attribute values, a range of numbers, or a part of a name.

  Sample Code

  ```
  POLICY salesOrders {
      GRANT read ON * WHERE Country = 'US';
  }
  ```

  Sample Code

  ```
  POLICY salesOrders {
      GRANT read ON * WHERE Country IN ('US','DE','FR');
  }
  ```

  Sample Code

  ```
  POLICY salesOrders {
      GRANT read ON * WHERE Country = 'DE' AND SalesID BETWEEN 100 AND 200;
  ```

```
}
```

Sample Code

```
POLICY salesOrders {
    GRANT read ON SalesOrders WHERE Name LIKE 'Winter%'
}
```

- This is a policy that allows all actions with restriction on special resources. Asterisk (*) means that all actions are granted. No attribute conditions restrict the policy.

Sample Code

```
POLICY salesOrders {
    GRANT * ON SalesOrders;
}
```

Sample Code

```
POLICY salesOrders {
    GRANT * ON SalesOrders, SalesOrderItems, SalesOrderLists;
}
```

- A policy with actions on special resources where additionally attribute values restrict the user authorization.

Sample Code

```
POLICY salesOrders {
    GRANT read, activate ON SalesOrders WHERE SalesOrders.Country = 'US'
                                          AND SalesOrders.SalesID BETWEEN
100 AND 300;
}
```

Sample Code

```
POLICY salesOrders {
    GRANT read, activate ON SalesOrders, SalesOrderItems WHERE
SalesOrders.Country = 'US'
                                                          AND
SalesOrders.SalesID BETWEEN 100 AND 300
                                                          AND
SalesOrderItems.Country = 'US'
                                                          AND
SalesOrderItems.SalesID BETWEEN 100 AND 200;
}
```

- Maybe if all attributes are related to all resources, you can keep the code short by entering only attributes with values which then relates to all resources.

Sample Code

```
POLICY salesOrders {
    GRANT read, activate ON SalesOrders, SalesOrderItems WHERE Country =
'US'
```

```
                                                                AND SalesID
BETWEEN 100 AND 300;
}
```

- A policy with multiple rules.

  Sample Code

  ```
  POLICY salesOrders {
      GRANT read ON * WHERE Country = 'US' AND SalesID BETWEEN 100 AND 200;
      GRANT write ON * WHERE Country = 'DE' AND SalesID BETWEEN 100 AND 200;
  }
  ```

You can create a policy with actions and restrict it to defined resources. Here you use `WHERE` with multiple conditions.

```
POLICY <policy_name> {
    GRANT <action1>, <action2> ON <resource> WHERE <attribute_name> =
'<attribute_value>'
                                        AND <attribute_name> BETWEEN <number>
AND <number>;
}
```

- Sample Code

  ```
  POLICY salesOrders {
      GRANT read, activate ON salesGroup WHERE salesGroup.Country = 'US'
                                           AND salesGroup.SalesID BETWEEN
  100 AND 300;
                                           }
  ```

- Sample Code

  ```
  POLICY salesOrders {
      GRANT read, activate ON salesGroup, salesGroupItems WHERE
  salesGroup.Country = 'US'
                                                          AND
  salesGroup.SalesID BETWEEN 100 AND 300
                                                          AND
  salesGroupItems.Country = 'US'
                                                          AND
  salesGroupItems.SalesID BETWEEN 100 AND 200;
                                                          }
  ```

- Sample Code

  ```
  POLICY salesOrders {
      GRANT read, activate ON salesGroup, salesGroupItems WHERE Country =
  'US'
                                                          AND SalesID
  BETWEEN 100 AND 300;
  }
  ```

You can also create a policy with multiple actions on the same resources depending on different conditions with attribute values.

```
POLICY <policy_name> {
    GRANT <action1> ON <resource> WHERE <attribute1> = '<attribute_value1>' AND
<attribute2> BETWEEN <number1> AND <number2>;
    GRANT <action2> ON <resource> WHERE <attribute1> = '<attribute_value2>' AND
<attribute2> BETWEEN <number1> AND <number2>;
}
```

- Sample Code

```
POLICY salesOrders {
    GRANT read ON * WHERE Country = 'US' AND SalesID BETWEEN 100 AND 200;
    GRANT write ON * WHERE Country = 'DE' AND SalesID BETWEEN 100 AND 200;
    }
```

Combining Authorization Policies

To combine multiple authorization policies, define a new policy, which includes already existing policies by `USE`.

```
POLICY <policy_name> {
    USE <policy_name1>;
    USE <policy_name2>;
}
```

- Sample Code

```
POLICY allAdmins {
    USE salesOrders;
    USE readAll;
    }
```

- You can give this new compound policy its own rules.

  Sample Code

```
POLICY allAdmins {
    USE salesOrders;
    USE readAll;
    GRANT write ON salesOrders WHERE Country IN ('US', 'DE');
    }
```

The `RESTRICT` clause allows you to narrow down the scope of an authorization policy. It enforces that an operation is permitted only when certain attribute-based conditions are true.

Sample Code

```
POLICY "SalesICADelUpdAdmins" {
   USE users.DELETE_USERS
      RESTRICT
         user.costCenter = 'SalesICA'
```

```
   USE users.UPDATE_USERS
      RESTRICT
         user.costCenter = 'SalesICA'
;
}
```

Combination Algorithms

The combination algorithms for policies, rules, and the list entries for actions and resources are fixed.

Combination Algorithms

Syntax Element	Combination Algorithm
Policy	Always **OR**
Rule	**OR**
Action	**OR**
Resource	**OR**

1.7.5.5.1.4 Base Authorization Policies

Base authorization policies are delivered with the respective application.

In the administration console, administrators can use them to create their own refined custom authorization policies, which they assign to users. We recommend that application developers define the base policies with the basic authorizations that are required for the specific application. For more information, see Configuring Authorization Policies [page 2244].

> **Note**
>
> Currently, the administration console doesn't support the creation of tenant-specific base policies.

1.7.5.5.2 Grammar and Syntax Rules

DCL has a set of grammar and syntax rules you must observe when you define authorization policies.

Parent topic: Data Control Language (DCL) [page 2251]

Related Information

Structure of the Data Control Language (DCL) [page 2252]
Advanced Features [page 2269]

1.7.5.5.2.1 Naming Conventions

Naming conventions in Authorization Management involve using regular or delimited identifiers for objects like policies, actions, resources, and attributes, ensuring consistency and clarity in application development. This content is useful for developers to understand how to properly name and manage authorization elements within their applications, promoting uniformity and preventing naming conflicts.

The objects of Authorization Management include authorization policies, actions, resources, and attributes. The names of actions, resources, and attributes are defined in the application and are sent to Authorization Management using the authorization content. A set of valid characters makes it possible for developers to define the names in the same style as all other elements used for development.

The user names and user groups names are defined in the identity provider. There is no naming convention from DCL side. Within DCL, we must handle all kinds of users and group names. It's possible to use unquoted and double-quoted names for users and user groups.

- The name for an object (authorization policy, action, resource, or attribute) can be specified using regular (unquoted) identifiers or delimited (double-quoted) identifiers:
  - Policy name specified using a regular identifier in a `POLICY` statement

    Sample Code

    ```
    POLICY readAll { ... };
    ```

  - Policy name specified using a delimited identifier in a `POLICY` statement:

    Sample Code

    ```
    POLICY "read All"  { ... };
    ```

  - Action name specified using a regular identifier:

    Sample Code

    ```
    GRANT read ON * ;
    ```

  - Action name specified using a delimited identifier:

    Sample Code

    ```
    GRANT "read" ON * ;
    ```

- The maximum length of an authorization policy is 127 characters.
- A name can't be identical to another object of Authorization Management with the same type. For example: there is only one authorization policy with name `Admin`.

String values of attributes are always quoted with `'` (single quotes). This is also valid for identifiers.

Sample Code

```
POLICY salesOrders {
    GRANT read ON SalesOrders, SalesOrderItems WHERE Country = 'DE'
}
```

1.7.5.5.2.2 Input Parameters for Authorization Policies

In authorization policies, you define rules with conditions using attribute constraints like `IS RESTRICTED` and `IS NOT RESTRICTED`, allowing for flexible user permissions based on attributes while restricting actions and resources.

In an authorization policy, you can define rules with conditions that contain the attribute constraint `IS NOT RESTRICTED`. If you assign such a policy to a user, it means that this user is fully authorized based on the attributes. Only the actions and resources are restricted.

In contrast, a condition containing the attribute constraint `IS RESTRICTED` means that this user's attribute-based authorization is restricted. This condition can be refined in a `USE` clause.

See the difference between `IS RESTRICTED` and `IS NOT RESTRICTED` in the example below. It shows how user authorizations only differ if no condition is given. In that case, `IS RESTRICTED` defaults to false, and `IS NOT RESTRICTED` defaults to true. However, if a condition is given (`CountryCode = 'IT'` in the example below), a specified restriction replaces either the general restriction or `IS NOT RESTRICTED`.

Example

Sample Code

```
POLICY readAll {
    GRANT read ON * WHERE CountryCode IS RESTRICTED;
    GRANT write ON * WHERE CountryCode IS NOT RESTRICTED;
}
POLICY readAllNoCondition {
    USE readAll;
}
POLICY readAllItaly {
    USE readAll RESTRICT CountryCode = 'IT';
}
TEST readAll {
    // Policy assigned directly
    EXPECT DENY FOR read ON * POLICY readAll; // If the policy is assigned
directly, IS RESTRICTED evaluates to false
    EXPECT GRANT FOR write ON * POLICY readAll; // If the policy is
assigned directly, IS NOT RESTRICTED evaluates to true
    // Policy USEd, but no condition for CountryCode is given
    EXPECT DENY FOR read ON * POLICY readAllNoCondition; // If the policy
is USEd, but no condition for CountryCode is given, IS RESTRICTED evaluates
to false
    EXPECT GRANT FOR write ON * POLICY readAllNoCondition; // If the policy
is USEd, but no condition for CountryCode is given, IS NOT RESTRICTED
evaluates to true

    // Policy USEd, and a condition for CountryCode is given
    EXPECT GRANT FOR read, write ON * POLICY readAllItaly INPUT
{CountryCode: 'IT'}; // If the policy is USEd and a condition for
CountryCode is given, both IS RESTRICTED and IS NOT RESTRICTED behave the
same way
```

```
    EXPECT DENY FOR read, write ON * POLICY readAllItaly INPUT
{CountryCode: 'DE'} // The same applies if the condition is not met
}
```

In the example below, the user is assigned to the `salesOrders` policy and is thus allowed to read all `SalesOrders`.

Example

Sample Code

```
POLICY salesOrders {
    GRANT read ON SalesOrders WHERE ( Country IS NOT RESTRICTED AND SalesID
IS NOT RESTRICTED )
                                  OR ( Country IS NOT RESTRICTED AND Name IS
NOT RESTRICTED);
}
```

With the assignment to the `salesOrdersWinter` policy, users can read all `SalesOrders`, which include the string '`Winter`' in their name.

Example

Sample Code

```
POLICY salesOrdersWinter {
    GRANT read ON SalesOrders WHERE ( Country IS NOT RESTRICTED
                                      AND SalesID IS NOT RESTRICTED AND
Name IS NOT RESTRICTED )
                                  OR ( Country IS NOT RESTRICTED AND Name
LIKE '%Winter%' );
}
```

These policy parameters can be filled while another policy is used. Here, the assignment of `use_salesOrders` allows users to read `salesOrders` in the countries DE, FR, or IT and with `SalesID 200`, or read `salesOrders` in the countries DE, FR, or IT and with a name that contains the string '`Winter`'.

Note

Include all conditions for a combination of resource and action in a single policy. This way, it's easy for administrators to decide which policy to use. It also ensures that the authorizations remain understandable.

Example

Sample Code

```
POLICY use_salesOrders {
    USE salesOrders RESTRICT Country IN ('DE','FR','IT'), SalesID = 200,
Name LIKE '%WINTER%';
}
```

You can repeat the `RESTRICT` section of a policy multiple times and thus define a list of tuples.

Example

Sample Code

```
POLICY salesOrders{
    GRANT read ON SalesOrders WHERE Country IS NOT RESTRICTED AND SalesID
IS NOT RESTRICTED ;
}
POLICY use_salesOrders {
    USE salesOrders RESTRICT Country = 'DE', SalesID = 300
                    RESTRICT Country = 'FR', SalesID = 200
                    RESTRICT Country = 'IT', SalesID = 100;
}
```

The previous definition is not equivalent to the following since it allows any combination of `Country` and `SalesID` (9 combinations in contrast to 3 combinations).

Example

Sample Code

```
POLICY use_salesOrders {
    USE salesOrders RESTRICT Country IN ('DE','FR','IT'), SalesID IN
(300,200,100);
}
```

The `WHERE` clause is deprecated for `USE` statements.

Caution

The correct syntax is `USE <basePolicy> RESTRICT <condition_for_attribute(s)>`. Don't use `WHERE` in a `USE` statement..

1.7.5.5.2.3 Condition Operators

Condition operators provide a set of tools for evaluating data, including equality, range, and pattern matching.

Condition Operators

Operators	Description
=	Equal
<	Less than
>	Greater than

Operators	Description
<=	Less than or equal
>=	Greater than or equal
<>	Not equal
IN	To specify multiple possible values
BETWEEN lower AND upper	Between a certain range, including upper and lower
LIKE pattern	Search for a string pattern (% any number of characters, _ any single character)
LIKE pattern ESCAPE escape-char	Allows searching for % and _ if they are prefixed and `escape-char.escape-char` is a string constant with exactly one character.
NOT IN	To specify multiple values which are not possible
NOT BETWEEN	Values, which aren't within a certain range
NOT LIKE	Values, which don't match the pattern
IS NULL	Attribute value is empty

LIKE Operators

The LIKE operator matches a given value with a pattern. This pattern can contain % for a sequence of 0 to n arbitrary characters and _ for exactly one character.

The escape clause allows specifying a single character, that escapes the pattern characters and hereby allows searching for this character in the input.

LIKE Operators

Pattern	Escape	Input	Matches	Comment
'AB'		'AB'	true	
		'ABC'	false	
'AB%'		'AB'	true	Implements "Starts with"
		'ABC'	true	
		'XABC'	false	

Pattern	Escape	Input	Matches	Comment
'%AB'		'AB'	true	Implements "Ends with"
		'ABC'	false	
		'XAB'	true	
'%AB%'		'AB'	true	
		'ABCD'	true	
		'XABC'	true	
		'A-B'	false	
'_'		'A'	true	
		'AB'	false	
		'ABC'	false	
'AB'	'!'	'AB'	true	Same as if no pattern were specified
		'ABCD'	false	
'AB!%'	'!'	'AB'	false	
		'ABC'	false	
		'AB%'	true	
'A!B'	'!'	'AB'	false	
		'A!B'	true	
'%%AB'	'%'	'AB'	false	
		'XAB'	false	
		'%AB'	true	

Compatibility of Operators and Data Types

Some combinations of operators and data types aren't allowed in DCL as shown in the table below. The compiler enforces these rules.

Compatibility of Operators and Data Types

Operator	String	Number	Boolean	Array (String[], Number[], Boolean[])	Structure
`a = b`	✓	✓	✓	×	×
`a < b`	✓	✓	✓	×	×
`a > b`	✓	✓	✓	×	×
`a <= b`	✓	✓	✓	×	×
`a >= b`	✓	✓	✓	×	×
`a <> b`	✓	✓	✓	×	×
`a [NOT] IN b`	✓ (for `a`)	✓ (for `a`)	✓ (for `a`)	✓ (for `b`)	×
`a [NOT] BETWEEN b AND a`	✓	✓	×	×	×
`a [NOT] LIKE` pattern	✓	×	×	×	×

1.7.5.5.2.4 Attribute Constraints

Use attribute constraints in authorization policy definitions to define conditions for accessing data, such as `IS NULL` and `IS RESTRICTED`.

Attribute Constraints

Constraint	Description
`IS RESTRICTED`	Denies access until it's relaxed in a `RESTRICT` clause of the `USE` statement
`IS NOT RESTRICTED`	Authorizes access until it's constrained in a `RESTRICT` clause of the `USE` statement

Sample Code

```
POLICY salesOrders {
    GRANT read, write ON SalesOrderItems WHERE Status IS NULL;
}
```

Sample Code

```
POLICY CreateOrders {
    GRANT create ON orders WHERE order.total IS RESTRICTED AND
product.category IS NOT RESTRICTED;
}
POLICY CreateSmallOrders {
     USE CreateOrders RESTRICT order.total < 50, product.category IS NOT
RESTRICTED;
}
POLICY CreateSmallAccessoryOrders {
     USE CreateOrders RESTRICT order.total < 50, product.category =
'accessory';
}
```

Only use the `IS (NOT) RESTRICTED` attribute constraint for attributes of the data type string, number, and Boolean. It's not allowed for arrays and structures.

1.7.5.5.3 Advanced Features

You find advanced configuration techniques for authorization policies, focusing on annotations, formatting conventions, and internal functions for enterprise-grade authorization policies.

Parent topic: Data Control Language (DCL) [page 2251]

Related Information

Structure of the Data Control Language (DCL) [page 2252]
Grammar and Syntax Rules [page 2261]

1.7.5.5.3.1 Annotations

Use annotations, for example, to insert a description of the authorization policy.

@description

Use a `@description` annotation to define a description of the policy.

```
@description: '<policy_description'
POLICY <policy_name> {
    GRANT <action> ON <resource1>, <resource2> WHERE <attribute_name> =
'<attribute_value>'
```

```
}
```

- Sample Code

```
@description: 'Policy for reading sales orders for USA'
POLICY salesOrders {
    GRANT read ON salesGroup, salesGroupItems WHERE Country = 'US'
}
```

@label

Use this annotation to define a policy display name that can be changed by the customer.

Sample Code

```
@label: 'Sales Order Policy'
POLICY salesOrders {
    GRANT read ON salesOrders, salesOrderItems WHERE Country = 'US'
}
```

1.7.5.5.3.2 Formats

Here you find rules for creating valid identifiers in DCL, such as how to quote and how to separate packages. Identifiers are basically similar to Java identifiers.

Identifier Format

1. An unquoted identifier must begin with a Unicode character
   - Uppercase letter
   - Lowercase letter
   - Title case letter
   - Modifier letter
   - Other letter
   - Letter number
   - Currency symbol
   - Connector punctuation
2. Next, you can use the following characters.
   - A start character from above
   - Digit

> ### Note
>
> Don't use the following characters.

- Surrogate
- Formatting character
- Modifier symbol
- Modifier letter

Identifiers are basically similar to Java identifiers.

> ### Example
>
> `µSeconds`, `PublicTransport`

Enclose an identifier by the double quotes (`" ... "`) if you use dots or blank spaces. Remember that this also applies for keywords like `POLICY`.

A quoted identifier can contain any character that isn't a surrogate.

> ### Example
>
> `/value$to`

In a quoted identifier, the character `"` (double quote) must be escaped. See escaping rules.

Identifiers are case-sensitive. For example, `CUSTOMER` and `Customer` are not the same identifiers.

An unquoted identifier is equal to the same text in double quotes.

String Constant Format

A string constant must begin and end with a single quote (`'`).

> ### Sample Code
>
> ```
> POLICY salesOrdersProduct {
>     GRANT read ON product WHERE Country = 'US';
> }
> ```

Keywords

> ### Note
>
> Keywords are case insensitive. This means that `KEYWORD`, `keyword`, `Keyword`, or `KeyWoRd` are all valid notations for the same.

Escaping Rules

The following escape sequences are defined within string constants and quoted identifiers.

Escaping Rules

Sequence	Value
`\"`	`"`
`\\`	`\`
`\t`	Tabulator
`\uHHHH`	Unicode `HHHH`
`\n`	New line
`\r`	Carriage return
`\f`	Form feed
`\b`	Backspace
`\/`	`/` (compliance for JSON)

Hints for Tools to Generate DCL

- Avoid generating an unquoted identifier format. Always use double-quoted strings and escape at least the characters `"` (double quote) and `\` (backspace).
- When generating string constants, escape at least the characters `'` (single quote) and `\` (backspace).
- It's not necessary to quote package qualifiers like `a.b.c.d` because a package name mustn't contain special characters. However, package segments can be quoted, for example `"a"."b"."c"."d"."Policy Name"` is equal to `a.b.c.d."Policy Name"` in a DCL source file.

1.7.5.5.3.3 Default Authorization Policies

Default authorization policies are special base policies applied at runtime without an explicit assignment to a user. They needn't be passed to the DCN runtime explicitly, similar to internal polices.

Both default and internal policies are special cases of base authorization policies. Base policies are all policies that are defined by the developers of the application and deployed together with the application. They exist in

all tenants. However, custom policies are created specifically for a customer by administrators. Custom policies only exist in the customer's SAP Cloud Identity Services tenants.

You can define an authorization policy as a default authorization policy by using the `DEFAULT` element.

Sample Code

```
DEFAULT POLICY defaultSalesOrders {
    GRANT read ON SalesOrders, SalesOrderItems WHERE salesGroup IN
$user.groups
}
```

The `defaultSalesOrders` default policy can't be assigned to a user because it's automatically evaluated by the runtime.

1.7.5.5.3.4 Internal Policies

Developers can create authorization policies for internal purposes. The policies aren't deployed and don't appear in the administration console.

You can use internal authorization policies and map them to a technical client, for example for app-to-app communication. In this case, the policies are set at runtime and are passed to the decision engine in the client libraries. For more information, see SAP Cloud Identity Services Developer Guide .

You can create internal policies by using the keyword `INTERNAL`.

Effect of Using the INTERNAL Keyword

Element	Description	Effect
Base policy	A USE of such a policy isn't allowed.	Compile error
Tenant-specific policy	Annotation isn't allowed at tenant level.	Compile error

In a downstream tool like Authorization Management, an `INTERNAL` element doesn't show in the user interface. This prevents reuse (not allowed as described above) and policy assignment.

You can't combine an `INTERNAL POLICY` with `DEFAULT`. It should be explicitly set with the DCL runtime client API. You can also mark it with `INTERNAL`.

1.7.6 Configuring Terms of Use

You can configure a custom terms of use document by creating a new document, adding and editing its language versions, and defining the document for an application.

Every time you want to update the terms of use document you add a new language versions for the document.

Each terms of use document can have one draft and one active version. You can view all language version in the administration console. Optionally you can edit the draft version of a document before making it an active version.

Once a terms of use document is created it can't be renamed.

For each language version, you have to upload a text file. You can define a terms of use document in the following languages:

Arabic, Azerbaijani, Bulgarian, Catalan, Chinese (PRC), Chinese (Taiwan), Croatian, Czech, Danish, Dutch, English (United Kingdom), English (United States), Estonian, Finnish, French (Standard), French (Canada), German (Standard), Greek, Hebrew, Hungarian, Italian, Japanese, Korean, Latvian, Malay, Norwegian, Polish, Portuguese (Portugal), Romanian, Russian, Serbian, Slovak, Slovenian, Spanish (Standard), Spanish (Mexico), Swedish, Thai, Turkish, Ukrainian, Vietnamese, Welsh.

The language is defined in the following order of importance:

- By the `locale` parameter in the URL used for accessing the application.

  > **Note**
  >
  > If the SP is configured to support a specific language, only this language is used by the application.

- By the language of the application's browser.

  > **Note**
  >
  > The application takes the browser language only if the SP's language is not selected, and the `locale` parameter isn't set in the URL. The default browser setting is *English*.

> **Note**
>
> If there is only one language for the document, it is recommended to be *English (United States)*.
>
> If the languages are more than one, one of them must be *English (United States)*.

To configure terms of use in the administration console, do the following:

1. Create a New Terms of Use Document [page 2275]
   Create a new terms of use document in the administration console.
2. Add New Language of a Terms of Use Document [page 2276]
   To add a new language of a terms of use document, you must upload a UTF-8 encoded plain text file containing the terms of use statement.
3. Add New Version of a Terms of Use Document [page 2277]
