1.7.6.1 Create a New Terms of Use Document

Create a new terms of use document in the administration console.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Application & Resources*, choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. Choose the *+Add* button on the left-hand panel in order to add a new terms of use document to the list.
4. Specify a name for the document.

   > ⓘ Note
   >
   > The name can contain only Latin letters, numbers or the underscore character, or a combination of them. The lowercase letters are converted to uppercase letters.
5. Save your selection

   Once the document has been created, the system displays the message `Terms of use document <name of document> created`.

Task overview: Configuring Terms of Use [page 2273]

Next task: Add New Language of a Terms of Use Document [page 2276]

1.7.6.2 Add New Language of a Terms of Use Document

To add a new language of a terms of use document, you must upload a UTF-8 encoded plain text file containing the terms of use statement.

Prerequisites

You have created a terms of use document in the administration console. For more information, seeCreate a New Terms of Use Document [page 2275] .

Context

You can add one or more languages of the document.

> **Note**
>
> If there is only one language for the document, it is recommended to be *English (United States)*.
>
> If the languages are more than one, one of them must be *English (United States)*.

The plain text document can include the following tags: `<a>`, `<strong>`, and `<em>`.

> **Example**
>
> - `See <a href="https://www.example.com">Subscription conditions</a>`
> - `<strong>Additional requirements</strong>`
> - `<em>Important:</em>`

To open the link from the document in the preview in the admin console, right-click the link and open it in a new tab.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.

3. To add a language to a terms of use document, choose that document from the list on the left.

> → Tip
>
> Type the name of the document in the search field to filter the list items.

4. Choose the *Add* button in the details view on the top right-hand corner.
   a. Choose the *Active Language Version* radio button.
   b. Select the language from the drop-down.
   c. Specify the plain text file for the language.

   > ⓘ Note
   >
   > Use a file with an extension `.txt`.

   d. Choose *Add* to save your selection

      Once the file has been uploaded, the system displays the message `Terms of use file uploaded`.

Task overview: Configuring Terms of Use [page 2273]

Previous task: Create a New Terms of Use Document [page 2275]

Next task: Add New Version of a Terms of Use Document [page 2277]

1.7.6.3 Add New Version of a Terms of Use Document

Add a new version of a terms of use document and make it active.

Context

To update an existing terms of use document you must add a new version for each language of this document by uploading a UTF-8 encoded plain text file containing the updated terms of use statement. Once the new version is uploaded it is in a status draft. You must activate it to replace the current active version. To make a draft version active, you must have draft versions for all the languages that the current active version has.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. To add a new language version to a terms of use document, choose that document from the list on the left.

> → Tip
>
> Type the name of the document in the search field to filter the list items.

4. Choose the *Add* button in the details view on the top right-hand corner.
   a. Choose the *Draft Language Version* radio button.
   b. Select the language from the drop-down for that version.
   c. Specify the plain text file for the language.

      > ⓘ Note
      >
      > Use a file with an extension `.txt`.

   d. Choose *Add* to save your selection

      Once the file has been uploaded, the system displays the message `Terms of use file uploaded`.
5. Repeat the procedure for all languages that have active versions.
6. **Optional:** To make the draft version active, choose *Activate* in the details view on the top right-hand corner.

Task overview: Configuring Terms of Use [page 2273]

Previous task: Add New Language of a Terms of Use Document [page 2276]

Next task: Define a Terms of Use Document for an Application [page 2278]

1.7.6.4 Define a Terms of Use Document for an Application

Context

The terms of use document is displayed on the registration form, which form appears when the user chooses the *Register Now* link on the logon page. It is also shown to the user when the registration information has been upgraded. By default, the application is set not to use a terms of use document on the registration and upgrade forms. To change this configuration, you have to update the *None* setting in the administration console.

If you have the authorization, you can create a custom terms of use document. This document is used once you have set it for the respective application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *POLICIES*, choose *Terms of Use*.
6. Select the radio button for the Terms of Use.
7. Save your selection.

Task overview: Configuring Terms of Use [page 2273]

Previous task: Add New Version of a Terms of Use Document [page 2277]

Next task: (Optional) View and Edit a Terms of Use Document [page 2279]

Related Information

Create a New Application [page 1922]

1.7.6.5 (Optional) View and Edit a Terms of Use Document

Tenant administrators can view terms of use documents uploaded in the administration console for SAP Cloud Identity Services and optionally edit the draft versions of those documents.

Context

The content of the terms of use documents are visualised in the administration console

Task overview: Configuring Terms of Use [page 2273]

Previous task: Define a Terms of Use Document for an Application [page 2278]

Next task: (Optional) Delete a Terms of Use Document [page 2281]

View a Terms of Use Document

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. Choose the document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose the version and language from the drop down.

   The content is displayed on the screen.

   To view another terms of use document, repeat the procedure.

Edit a Draft Version

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. Choose the document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose the draft version from the drop down.
5. Choose a language for the draft version from the drop down.
6. Choose *Edit* in the details view on the top right-hand corner.
7. Upload the edited document.
8. Choose *Edit* in the popup to confirm your changes.

1.7.6.6 (Optional) Delete a Terms of Use Document

Delete a terms of use document set or a version of a terms of use document.

Context

You can delete a specific language version or the entire set of terms of use documents. Deleting the entire set of terms of use documents, you delete all language versions for this set. The terms of use document set is removed from the list of the document sets in the administration console for SAP Cloud Identity Services, when you delete it.

The documents will be deleted no matter if they are accepted or not by any users.

> ⓘ Note
>
> You can delete only documents that are not defined for applications. To delete a document version or entire document sett that is defined for an application, you first you must set another terms of use for the applications. For more information, see Define a Terms of Use Document for an Application [page 2278].

Task overview: Configuring Terms of Use [page 2273]

Previous task: (Optional) View and Edit a Terms of Use Document [page 2279]

Delete Entire Documents Set

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. To delete the entire terms of use document set, choose that set from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.
4. Choose *Delete Set* button and confirm the operation in the pop-up that appears.

   If a document is defined for an application, define a new terms of use document for that application and repeat the step.

   If the document set is deleted, the system displays the message `Terms of Use document set deleted`.

Delete a Language Version

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Terms of Use Documents* tile.

   This operation opens a list of the terms of use documents.
3. To delete a language version to a terms of use document, choose that document from the list on the left.

   > → Tip
   >
   > Type the name of the document in the search field to filter the list items.

   a. Select the version from the drop-down that you want to delete.
   b. Select the language from the drop-down for that version that you want to delete.
   c. Choose *Delete* button and confirm the operation in the pop-up that appears.

      If the document is defined for an application, define a new terms of use document for that application and repeat the step.

   If the document version is deleted, the system displays the message `Terms of Use document deleted`.

1.7.7 Configuring Email Templates

Tenant administrators can use the default or a custom email template set for the application processes.

Overview

The email template set is a semantic grouping of different email templates. Each email template from the set is used for the respective application process, such as self-registration, for example. When a user makes a registration for an application, Identity Authentication uses the email template for self-registration from the template set to communicate with that user.

The administration console for SAP Cloud Identity Services provides the possibility to use a default email template set with English templates only. The default set is named *Default*.

You can also configure your own templates in a custom template set. There you can customize the texts and branding according to your needs.

You can define a set of email templates with different language versions for the following processes:

Email Template	Request Flow	Description
Self-Registration	User	This email template is used when a user registers via the Registration page. The user then receives an email with instructions about how to activate his or her account. The name of the email template used for this process is *Self-Registration*.
On-Behalf Registration	System	This email template is used when somebody else registers the user on his or her behalf via the import user option for Identity Authentication. In this case, the registered user receives an email with instructions about how to activate his or her account. The name of the email template used for this process is *On-Behalf Registration*.
Invitation	System	This email template is used when a user invites another user for registration via the Invitation REST API. In this case, the invitee receives an email with instructions about how to register. The name of the email template used for this process is *Invitation*.
Forgot Password	• User • System	This email template is used when: • a user wants to change his or her password by going through the Forgot Password page. In this case, the user receives an email with instructions about how to change his or her password. The name of the email template used for this process is *Forgot Password*. • an administrator sends a reset password email via the administration console. For more information, see Send Reset Password Email [page 2381].

Email Template	Request Flow	Description
Locked Password	System	This email template is used when a user locks his or her password by exceeding the allowed number of logon attempts. In this case, the user receives an email with instructions about how to log on. The name of the email template used for this process is *Locked Password*.
Reset Password	System	This email template is used when: a user has to reset his or her password. In this case, the user receives an email with instructions about how to reset his or her password. The name of the email template used for this process is *Reset Password*. The email template for *Reset Password* process are used when the process is triggered from the system, based on the password policy (for example, the user's password length is not enough according to the password policy requirements) and the user receive reset password notification email.
Deactivate TOTP Device	User	This email-template is used when a user has requested to receive a passcode via email. The passcode is used to deactivate the devices used to generate passcodes for TOTP Two-Factor Authentication. The name of the email template used for this process is *Deactivate TOTP Device*.
Email OTP Code	User	This email-template is used when a user has requested to receive an 8-digit code via email. The user needs the code for two-factor authentication.

Email Template	Request Flow	Description
Send Security Alert	System	This email-template is used when the user's password is set, changed, or reset, the email, or login name is changed, or when TOTP or Web TFA devices are activated or deactivated. The name of the email template used for this process is *Send Security Alert*. **Note** The sending of security alert emails is switched off by default. For more information, see Send Security Alert Emails [page 2209].

To activate a user registration or to reset a password, users choose links sent to them in the emails. For these cases, you can use placeholders. For more information about which placeholders can be used, see Edit or Add an Email Template Set [page 2289].

Restriction

If you select a corporate identity provider, the option to configure email templates is not possible. In this case you can access only some of the custom configurations for the applications. The configurations under the *Authentication and Access* and *Branding and Layout* tabs are partially visible. For more information, see Choose Default Identity Provider for an Application [page 2067].

You can also define which languages each email template uses, and you can set custom versions for each language. You can set the following languages:

Arabic, Azerbaijani, Bulgarian, Catalan, Chinese (PRC), Chinese (Taiwan), Croatian, Czech, Danish, Dutch, English (United Kingdom), English (United States), Estonian, Finnish, French (Standard), French (Canada), German (Standard), Greek, Hebrew, Hungarian, Italian, Japanese, Korean, Latvian, Malay, Norwegian, Polish, Portuguese (Portugal), Romanian, Russian, Serbian, Slovak, Slovenian, Spanish (Standard), Spanish (Mexico), Swedish, Thai, Turkish, Ukrainian, Vietnamese, Welsh.

The language for the email template sets is set according to the following order of priorities:

User request flow - when the user requests a process, for example Forgot Password, the emails use the language that the user's browser is set to.

- If the language isn't in the list of supported languages, the emails use *English*.
- If the language is in the list of supported languages, but there isn't a template for that language, the emails use English.
- If the language is in the list of supported languages, and there is a template for that language, the emails use this language.

System request flow - for example when the administrator chooses the Reset Password option in the administration console, the emails use the language set in the profile of the user. If there isn't a template for that language, the emails use *English* instead.

If you want to use a custom email template you should create one if it doesn't exist. Add or edit the email template set, if necessary, and then define that email template set for the application. To add or edit the email template, first you must open the uploaded email templates, and then save a copy. Optionally you can delete an email template set or a language version for a specific application process.

You can perform the following steps:

Create a New Email Template Set [page 2287]
: Tenant administrators can create a new set of email templates so that each template in the set can have a custom language version.

View Email Template Document [page 2288]
: Tenant administrators can view language email templates in the template set uploaded in the administration console for SAP Cloud Identity Services.

Edit or Add an Email Template Set [page 2289]
: Tenant administrators can configure language versions of each template in the template set. They can also set a custom template for each language, and change the name of each template set.

Define an Email Template Set for an Application [page 2295]
: Tenant administrators can define the email template set that the application uses.

Delete an Email Template Set [page 2297]
: Tenant administrators can delete an email template set or a language version for a specific application process.

Allowed Placeholders per Email Template [page 2298]
: This document describes which placeholders can be used in each email template.

1.7.7.1 Create a New Email Template Set

Tenant administrators can create a new set of email templates so that each template in the set can have a custom language version.

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

To create an email template, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Application & Resources*, choose the *Email Template Sets* tile.

   This operation opens a list of the template sets.
3. Press the *Add* button on the left-hand panel to add a new template set to the list.
4. Specify a name for the set.
5. Save your selection

   Once template has been created, the system displays the message `Template set <name of set> created`.

Allowed Placeholders per Email Template [page 2298]

1.7.7.2 View Email Template Document

Tenant administrators can view language email templates in the template set uploaded in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have added the plain text and HTML template files in the email template set. For more information, see Edit or Add an Email Template Set [page 2289].

> **Note**
>
> Both the TXT and HTML formats are included in the emails sent to a user. What the user sees, depends on the settings of his or her email client.

Context

You can view both the TXT and HTML formats of the emails sent to a user.

To view an email template, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Email Template Sets* tile.

   This operation opens a list of the template sets.
3. Choose the list item of the template set you want to view.
4. Select the tab signifying the process, whose template you want to view.
5. View the file:
   - To view the plain text file, choose the plain text file icon next to the respective language version.
   - To view the HTML file, choose the HTML file icon next to the respective language version.

   The file opens in a new tab.

   To view another template, repeat the procedure.

Allowed Placeholders per Email Template [page 2298]

1.7.7.3 Edit or Add an Email Template Set

Tenant administrators can configure language versions of each template in the template set. They can also set a custom template for each language, and change the name of each template set.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have prepared the plain text (TXT) and HTML template files that will be added in the email template set.
  For that purpose, you need to open the default template set for the respective application process in the administration console. After that, copy and paste the texts in a new file, edit the texts according to your needs, and save a copy of your versions of the documents. For more information how to open the default templates, see View Email Template Document [page 2288].

  > → Remember
  >
  > .Both, the TXT and HTML template files, must be saved with UTF-8 encoding.

  If you want to use a custom template set in another language, first you need to open the template set for the respective application process in the administration console. After that, copy and paste the texts in a new file, edit the texts in the respective language, and again save a copy of your versions of the documents. For more information how to open the default templates, see View Email Template Document [page 2288]

  > ⚠ Caution
  >
  > You should use only the placeholders used in the template documents. If you use other placeholders, even if they are in comments, emails for the respective process will not be sent. For more information, see Allowed Placeholders per Email Template [page 2298].
  >
  > When you edit texts in languages written in Right-To-Left (RTL) direction check that the placeholders are situated in the right place.

→ Remember

If you do not specify a version for a custom template of a specific process, users will receive the email from the default template set for this process. If you do not set an email template for the self-registration process for example, users will receive the default activation email when they complete the registration.

If you do not specify a language version for a custom template of a specific process, users will receive the email from the default template set for this process.

ⓘ Note

Both the HTML and TXT formats are included in the emails sent to a user. What the user sees, depends on the settings of his or her email client.

Context

To edit or add an email template, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Email Template Sets* tile.

   This operation opens a list of the template sets.
3. Choose the list item of the template set you want to edit.
4. **Optional:** To change the name of the template set, choose it.
5. Select the tab signifying the process, which you want to add or change the template for.
6. Add another language version by choosing the *+Add Language* button or edit an existing language version by selecting the respective list item.
   a. Choose language from the dropdown.

      ⓘ Note

      The dropdown is grayed out when you are editing an existing language version.

   b. Specify the subject.

      This is the subject of the email that the user receives for the respective process. You are allowed to include placeholders in the subject's text.

      ⓘ Note

      The subject must contain at least one non-space character.

   c. Upload the plain text template file that you have prepared.

The text file can contain placeholders and HTML tags. For more information about the allowed placeholders, see Allowed Placeholders per Email Template [page 2298].

> **→ Remember**
>
> The *${other.securityAlertText}* is mandatory for the *Send Security Alert* template. The *${other.securityAlertText}* is customizable. For more information, see Change Tenant Texts REST API [page 2826]. The key-value pairs that should be changed are `security.alert.<name of the flow>`.
>
> The *${other.totpResetPasscode}* is mandatory for the *Deactivate TOTP Device* template.

See examples for the *Deactivate TOTP Device* and *Email OTP Code* templates below:

Deactivate TOTP Device

> **Example**
>
> Dear ${user.firstName} ${user.lastName},
>
> The passcode to deactivate your Two-Factor Authentication device is ${other.totpResetPasscode}.
>
> Best regards,
>
> Your System Administrator
>
> This email may contain trade secrets or privileged, undisclosed, or otherwise confidential information. If you have received this email in error, you are hereby notified that any review, copying, or distribution of it is strictly prohibited. Please inform us immediately and destroy the original transmittal. Thank you for your cooperation.

Email OTP Code Template

> **Example**
>
> Dear ${user.firstName} ${user.lastName},
>
> The code for Email Two-Factor Authentication is ${other.emailOtpCode}.
>
> Best regards,
>
> Your System Administrator
>
> This email may contain trade secrets or privileged, undisclosed, or otherwise confidential information. If you have received this email in error, you are hereby notified that any review, copying, or distribution of it is strictly prohibited. Please inform us immediately and destroy the original transmittal. Thank you for your cooperation.

d. Upload the HTML template file that you have prepared.

The content of the HTML file must comply with the HTML markup requirements, and the file can contain placeholders. For more information about the allowed placeholders, see Allowed Placeholders per Email Template [page 2298].

> **→ Remember**
>
> The *${other.securityAlertText}* is mandatory for the *Send Security Alert* template. The *${other.securityAlertText}* is customizable. For more information, see Change Tenant Texts REST

API [page 2826]. The key-value pairs that should be changed are `security.alert.<name of the flow>`.

The *${other.totpResetPasscode}* is mandatory for the *Deactivate TOTP Device* template.

See examples for the *Deactivate TOTP Device* and *Email OTP Code* templates below:

Deactivate TOTP Device Template

            </td>
        </tr>
    </table>
</body>
</html>
```

7. Save your selection.

   Once the email template has been updated, the system displays the message `Email template <name of template> updated`.

Results

When you edit a previous version of a template in the template set, the changes are applied immediately. The email that is sent contains the latest changes.

When you create a new template set, you must assign the new template set to the application. If you do not assign it, the application will use the currently assigned template.

1.7.7.4 Define an Email Template Set for an Application

Tenant administrators can define the email template set that the application uses.

Context

Initially, the application uses a default template set with an English language version for all the templates in the set. This template set is named *Default*. If you want to use another email template set, assign it to the respective application.

> **Note**
>
> Both the HTML and TXT formats are included in the emails sent to a user. What the user sees, depends on the settings of his or her email client.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Branding and Layout* tab.
5. Under *EMAIL CONFIGURATIONS*, choose *Email Template Set*.
6. Select the radio button of the email template set the application will use.
7. Save your selection.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Next Steps

(Optional) Configure custom mail server. To use own mail server for the emails sent for the different application processes, you should configure your mail server in the administration console for SAP Cloud Identity Services.

For more information, see Configure Mail Server for Application Processes [page 2195].

1.7.7.5 Delete an Email Template Set

Tenant administrators can delete an email template set or a language version for a specific application process.

Context

You can delete only email template sets that aren't assigned to applications. If you want to delete an email template that is assigned to an application, first you must choose another email template set for the applications.

You can't delete the default template set.

If you delete a language version for specific application process, users receive the email from the default template set for this process. If you delete the email template for the self-registration process, for example, users receive the default activation email when they complete the registration.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Email Template Sets* tile.

   This operation opens a list of the template sets.
3. Choose the list item of the template set you want to edit.

Option	Result
Select the tab signifying the process, and delete the respective language version of the template. Repeat the operation as many times as necessary.	Deletes a language version for specific application process.
Choose the *Delete* button at the lower right corner of the screen.	Deletes the entire email template set

1.7.7.6 Allowed Placeholders per Email Template

This document describes which placeholders can be used in each email template.

The allowed placeholders are marked with *Yes* in the table:

Placeholders per Email Template

Placeholder/ Email Template	Self-Registration	On-Behalf Registration	Invitation	Forgot Password	Locked Password	Reset Password	Send Security Alert	Deactivate TOTP Device	Email OTP Code
`${user.sp_name}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.activate_account_link}`	Yes	Yes	Yes	No	No	No	No	No	No
`${user.firstName}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.lastName}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.mail}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.uid}`	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes
`${user.ids_home_link}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.loginName}`	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes
`${user.company_logo}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Placeholder/ Email Template	Self-Registration	On-Behalf Registration	Invitation	Forgot Password	Locked Password	Reset Password	Send Security Alert	Deactivate TOTP Device	Email OTP Code
`${user.sap_mailing_logo}`	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
`${user.target_url}`	No	Yes	Yes	No	No	No	No	No	No
`${user.reset_password_link}`	No	No	No	Yes	No	Yes	No	No	No
`${user.set_locked_password_link}`	No	No	No	No	Yes	No	No	No	No
`${other.securityAlertText}`	No	No	No	No	No	No	Yes/ Mandatory	No	No
`${other.totpResetPasscode}`	No	No	No	No	No	No	No	Yes	No
${other.emailOtpCode}	No	No	No	No	No	No	No	No	Yes
`${user.inviter_name}`	No	No	Yes	No	No	No	No	No	No
`${user.footer}`	No	No	Yes	No	No	No	No	No	No

Placeholder/ Email Template	Self-Registration	On-Behalf Registration	Invitation	Forgot Password	Locked Password	Reset Password	Send Security Alert	Deactivate TOTP Device	Email OTP Code
`${user.header}`	No	No	Yes	No	No	No	No	No	No

Placeholder	Notes
`${user.sp_name}`	The name of the application for which the email is sent.
`${user.activate_account_link}`	The account activation link sent to the user in the email.
`${user.firstName}`	The first name of the user.
`${user.lastName}`	The last name of the user.
`${user.mail}`	The email of the user.
`${user.uid}`	The user universal unique identifier (Global User ID) number.
`${user.ids_home_link}`	
`${user.loginName}`	The login name of the user.
`${user.company_logo}`	The application logo shown on the logon page and in the emails sent to users.
`${user.sap_mailing_logo}`	
`${user.target_url}`	The URL that the user is redirected to after registration.
`${user.reset_password_link}`	The link provided in the email to reset the password.
`${user.set_locked_password_link}`	The link provided in the email to set a new password,
`${other.securityAlertText}`	The text for the specific security alert.
`${other.totpResetPasscode}`	
${other.emailOtpCode}	
`${user.inviter_name}`	
`${user.footer}`	
`${user.header}`	

→ Remember

The *${other.securityAlertText}* is mandatory for the *Send Security Alert* template. The *${other.securityAlertText}* is customizable. For more information, see Change Tenant Texts REST API [page 2826]. The key-value pairs that should be changed are `security.alert.<name of the flow>`.

The *${other.totpResetPasscode}* is mandatory for the *Deactivate TOTP Device* template.

See example for the *Deactivate TOTP Device* template below:

1.7.8 Managing Administrators

This section describes how, as a tenant administrator, you can list all administrators in the administration console for SAP Cloud Identity Services, add new administrators, and edit the administrator authorizations. You can also remove administrators.

List Administrators [page 2302]
As a tenant administrator, you can list the administrators and their authorizations in the administration console for SAP Cloud Identity Services.

Add Administrators [page 2303]
As a tenant administrator, you can add new administrators in the administration console for SAP Cloud Identity Services.

Edit Administrator Authorizations [page 2309]
As a tenant administrator, you can edit both your own authorizations and other administrators' authorizations in the administration console for SAP Cloud Identity Services. By editing the administrator authorizations you can also delete an administrator.

Configure Authorizations Based on Policies [page 2311]
Enable admin authorizations based on policies to configure a granular access control for the administrators of SAP Cloud Identity Services.

1.7.8.1 List Administrators

As a tenant administrator, you can list the administrators and their authorizations in the administration console for SAP Cloud Identity Services.

Context

To list all administrators, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Administrators* tile.

   This operation opens a list of all administrators in alphabetical order.

   > ⓘ Note
   >
   > The list also includes the SAP BTP system, which by default has authorizations to set up the trust with Identity Authentication.

3. Choose the name from the list item to view the profile details, such as user ID and email, and the authorizations assigned to the administrator.

   > → Tip
   >
   > Type the name of the administrator in the search field to filter the list items.

4. **Optional:** To change the name of the system as administrator choose the `Rename` button and enter the new display name.

> → Remember
>
> You can change only the name of the system.

1.7.8.2 Add Administrators

As a tenant administrator, you can add new administrators in the administration console for SAP Cloud Identity Services.

Prerequisites

To add new tenant administrators, you must be assigned the Manage Tenant Configuration role.

Context

You can add both a person and a system in the administration console to act as administrators. The system can receive the same roles and can perform the same actions as the human administrator.

Add Administrators via SAP for Me

1.7.8.2.1 Add User as Administrator

Context

> → Tip
>
> If you are not a tenant administrator, or you don't have the Manage Tenant Configuration role, as an alternative, you can view the tenant administrators of the tenants that are assigned to you and add new administrators in SAP Cloud Identity Services via the SAP for Me portal. For more information see Cloud Identity Services Administrators Card.

To add a person as a new tenant administrator, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Administrators* tile.

   This operation opens a list of all administrators in alphabetical order.

   > ⓘ Note
   >
   > The list also includes the SAP BTP system, which by default has authorizations to set up the trust with Identity Authentication.

3. On the left-hand panel press *Add* > *User*.
4. Make the appropriate entries in the *Identifier*, *First Name*, and *Last Name* fields for the user you want to add as an administrator.

   The *Identifier* field can take user `email` or `login name`:

   - If `email` is used, it must be unique for the tenant.
   - If `login name` is used, an existing user with that login name must exist.

   > → Remember
   >
   > Once the administrator is created, the *First Name*, *Last Name*, and *Identifier* fields are not editable from the administrator section. If you want to change the information you must go to the *User Management* section. For more information about how to edit the user information, see List and Edit User Details [page 2361].

5. Assign the required administrator roles for the user.

   To be a tenant administrator, a user must be assigned at least one of the following roles.

Administrator Roles

Authorization	Description
Manage Applications	This role gives the tenant administrator permission to configure applications and their authorization policies via the administration console.
Manage Corporate Identity Providers	This role gives the tenant administrator permission to configure the identity providers via the administration console.
Manage Users	This role gives the tenant administrator permission to manage, import, and export users via the administration console.
Read Users	This role gives the tenant administrator permission to retrieve user data and export users via the administration console and the SCIM REST API of Identity Authentication.
Manage Groups	This role gives the tenant administrator permission to create, edit, and delete groups via the administration console. The tenant administrator can also assign authorization policies to users.
Manage Tenant Configuration	This role gives the tenant administrator permission to manage tenant configuration and authorization assignment to users. Tenant administrators with that role can add additional roles to themselves or to other administrators.
Manage Identity Provisioning	This role gives the tenant administrator permission to configure identity provisioning. The tenant administrator is granted the main IPS_ADMIN role.

6. Save your changes.

1.7.8.2.2 Add System as Administrator

Context

To add a system as a new tenant administrator, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Administrators* tile.

   This operation opens a list of all administrators in alphabetical order.

> ### Note
>
> The list also includes the SAP BTP system, which by default has authorizations to set up the trust with Identity Authentication.

3. On the left-hand panel press *Add* > *System* .
4. Enter a name for the system in the provided field.

> ### Caution
>
> Be careful when you choose a name for your system as administrator. Once created, the name cannot be changed.

5. Assign the required administrator roles for the system and save your changes.

   To be a tenant administrator, a user must be assigned at least one of the following roles.

   Administrator Roles

Authorization	Description
Manage Applications	This role gives the tenant administrator permission to configure the applications via the administration console.
Manage Corporate Identity Providers	This role gives the tenant administrator permission to configure the identity providers via the administration console.This role gives the tenant administrator permission to configure the applications via the administration console.
Manage Users	This role gives the tenant administrator permission to manage, import, and export users via the administration console.
Read Users	This role gives the tenant administrator permission to retrieve user data and import users via the administration console and the SCIM REST API of Identity Authentication.
Manage Groups	This role gives the tenant administrator permission to create, edit, and delete user groups via the administration console. The tenant administrator can also assign authorization policies.
Manage Tenant Configuration	This role gives the tenant administrator permission to manage tenant configuration and authorization assignment to users. Tenant administrators with that role can add additional roles to themselves or to other administrators.

Authorization	Description
Access Proxy System API	This role gives the tenant administrator permission to access API for provisioning identities via proxy systems. This role is needed for provisioning scenarios where proxy systems in the Identity Provisioning admin console are configured for synchronizing user data to and from central identity management solutions (such as, the on-premise SAP Identity Management). In this case, you use the credentials of the admin user with *Access Proxy System API* role assigned for setting up the technical user in the identity management solution for communicating with Identity Provisioning.
Access Real-Time Provisioning API	This role gives the tenant administrator permission to access API for real-time provisioning of identities. This role is needed for provisioning scenarios where user data is provisioned real-time without running jobs (manual or scheduled ones) in Identity Provisioning. In this case, you use the credentials of the admin user with *Access Real-Time Provisioning API* role assigned for setting up the authentication mechanism of the provisioning system defined on the *Real-Time Provisioning* tile of the administration console for SAP Cloud Identity Services.
Access Identity Provisioning Tenant Admin API	This role gives the tenant administrator permission to access tenant API for running provisioning jobs. This role is needed for running provisioning jobs from an API client. The API is available on the SAP Business Accelerator Hub: SAP Cloud Identity Services *Identity Provisioning Service* *API Reference* *Jobs*. The URL for accessing the Tenant Admin API follows the pattern: `https://<IPS tenant host>/ips/publicapi/v1/startJob/{SourceSystemId}/jobs/{JobType}`.

6. Configure the method for authentication when the system is used. You can choose from the following two options:

   - *Certificate*
     You can upload a certificate, generate a new one, or insert it as a text.
     You must provide a Common Name (CN) and password to generate the certificate. Once the certificate is generated, it is saved as a *.p12* file. The system populates the *Insert as Text* field with it, and provides the certificate attributes in the Subject DN. The common name (CN) in the generated certificate is in the format `<common name>` (`<admin user ID>`), where common name is the CN provided

by the administrator, and admin user ID is the administrator's user id. The maximum length of the combination of `<common name>` (`<admin user ID>`) is 64 characters.

> **→ Tip**
>
> Identity Authentication, by default, supports the following as trusted certificate authorities (CA): SAP Passport CA G2, SAP SSO CA G2, SAP Cloud Root CA, SAP Global Root CA, DigiCert TLS RSA SHA256 2020 CA1, DigiCert Global Root CA, SAP Cloud Platform Client CA, ConnectivityCA.

> **⚠ Restriction**
>
> You can't use one and the same certificate for application and system as administrator authentication.

> **ⓘ Note**
>
> For real-time provisioning scenarios, you need to upload the certificate generated from the source application that initiated the immediate sync. If Identity Authentication acts as the source application, simply upload the certificate generated in the *Authentication Mechanism* screen under *Users & Authorizations* > *Real-Time Provisioning* > *Add Target System*.

- *Secrets*

> **ⓘ Note**
>
> You need a *Client ID* and *Secret* for system authentication. It is generated automatically with the creation of the system. The client ID is in the universally unique identifier (UUID) format. For example, `1ab7c243-5de5-4530-8d14-1234a26373ab`.

Choose the *+Add* button in the *Secrets* section, provide the required info in the pop-up, and save your entries.

Field	Info
Description	This field is optional.
Expire in	You can choose from three options: • 1 year • 2 years • Never

Make sure you save your client secret. You won't be able to retrieve it from the system later.
Once your secret is generated you can see a table with your secrets and information about them. You can generate up to 2 secrets per system.

1.7.8.3 Edit Administrator Authorizations

As a tenant administrator, you can edit both your own authorizations and other administrators' authorizations in the administration console for SAP Cloud Identity Services. By editing the administrator authorizations you can also delete an administrator.

Prerequisites

To edit tenant administrators' authorizations, you must be assigned the Manage Tenant Configuration role.

Context

To edit an administrator's authorizations, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Administrators* tile.

   This operation opens a list of all administrators in alphabetical order.

   > ⓘ Note
   >
   > The list also includes the SAP BTP system, which by default has authorizations to set up the trust with Identity Authentication.

3. Choose the administrator name whose authorizations you want to edit.

   > → Tip
   >
   > Type the name of the administrator in the search field to filter the list items.

4. Edit the administrator authorizations as required.

   > ⓘ Note
   >
   > To be a tenant administrator, a user must be assigned one or more of the following roles:
   >
   > Administrator Roles

Authorization	Description
Manage Applications	This role gives the tenant administrator permission to configure applications and their authorization policies via the administration console.

Authorization	Description
Manage Corporate Identity Providers	This role gives the tenant administrator permission to configure the identity providers via the administration console.
Manage Users	This role gives the tenant administrator permission to manage, import, and export users via the administration console.
Read Users	This role gives the tenant administrator permission to retrieve user data and export users via the administration console and the SCIM REST API of Identity Authentication.
Manage Groups	This role gives the tenant administrator permission to create, edit, and delete groups via the administration console. The tenant administrator can also assign authorization policies to users.
Manage Tenant Configuration	This role gives the tenant administrator permission to manage tenant configuration and authorization assignment to users. Tenant administrators with that role can add additional roles to themselves or to other administrators.
Manage Identity Provisioning	This role gives the tenant administrator permission to configure identity provisioning. The tenant administrator is granted the main IPS_ADMIN role.

> → Tip
>
> **Remove Administrator**
>
> If you remove all authorizations, the user or system will no longer be an administrator, and the name will be removed from the list on the left. However, removing all authorizations does not delete the user from the user data base of Identity Authentication.

You cannot remove the *Manage Tenant Configuration* role from your own user.

5. Save your changes.

   If the operation is successful, the system displays the message `Tenant administrator <name of tenant administrator> updated`.

1.7.8.4 Configure Authorizations Based on Policies

Enable admin authorizations based on policies to configure a granular access control for the administrators of SAP Cloud Identity Services.

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

To be able to configure authorizations based on policies, you must enable the feature via the admin console for SAP Cloud Identity Services. Once it's enabled, it may take up to 60 seconds before the administrator can see the *Authorization Policies* tab when accessing the administration console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Tenant Settings*.
3. Under *General*, choose *Policy-Based Authorizations*.
4. Enable the policy-based authorizations.

1.7.8.4.1 Configure User Authorizations

Configure a granular access control based on policies for the administrators of SAP Cloud Identity Services.

Prerequisites

You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Sometimes the administrator authorizations that are predefined in the tenant of SAP Cloud Identity Services aren't enough. The predefined administrator authorizations give unlimited data access. However, you may need to define authorization models with more complex instance restrictions for data access, as is the so-called attribute-based access control (ABAC). Administrators define authorization policies with user attributes and assign these policies to other administrators. Thus, one administrator can have access to a subset of the users in the tenant or to a subset of the attributes of the user.

Once it's enabled, it may take up to 60 seconds before the administrator can see the *Authorization Policies* tab when accessing the administration console application. Initially, only the base

policies are visible: `CREATE_USERS` , `DELETE_USERS`, `MANAGE_USERS`, `READ_USERS`, `UPDATE_USERS`, `CREATE_SCIM_SCHEMAS`, `DELETE_SCIM_SCHEMAS`, `MANAGE_SCIM_SCHEMAS`, `READ_SCIM_SCHEMAS`, `CREATE_GROUPS`, `DELETE_GROUPS`, `MANAGE_GROUPS`, `READ_GROUPS`, and `UPDATE_GROUPS`. You can create new authorization policies on the base of these policies and assign them to administrators.

> ### → Remember
>
> As of February 11, 2025, the `MANAGE_USERS` policy does not contain the read applications permission. You must add the `READ_APPLICATIONS` policy to the user or users if they need to see the *Import Users* tile in the administration console.

> ### ⓘ Note
>
> The Read Users authorization overrides the READ_USERS authorization policy, while the Manage Users authorization overrides all user authorization policies. For example, if administrator users are assigned the Read Users authorizations, they can read all users even if the same administrator users are configured in the authorization policy with a READ_USERS restriction.

When you create a new policy, you can restrict the users on the basis of the following attributes: `user.name`, `user.addresses.country`, `user.costCenter`, `user.division`, `user.department`, `user.organization`, and `user.type`. The subsets of the user attributes are configured via the `user.attributes`.

User Attributes

Attributes	Value
`user.userName`	The *Login Name* of the user as defined in the administration console.
`user.addresses.country`	The value must match the predefined master data one. See Countries.properties [page 2873]. The addresses must be marked as primary via the Identity Directory SCIM REST API. Users who don't have a primary address are excluded even if the `user.addresses.country` attribute matches the address of the user. **→ Tip** Use the key from the key-value pair for the value of the `user.country` attribute. For example, you must use `DE` from the key-value pair `DE=Germany`.
`user.costCenter`	The *Cost Center* of the user as defined in the administration console.
`user.division`	The *Division* of the user as defined in the administration console.
`user.department`	The value must match the predefined master data one. See Departments.properties [page 2868]

Attributes	Value
`user.organization`	The *Company* of the user as defined in the administration console.
`user.type`	The *User Type* as defined in the administration console. The allowed values are `public`, `partner`, `customer`, `external`, `onboardee`, `employee` or `alumni`.
`user.attributes`	The policy allows you to see the attributes that are defined in the value field. The attributes' value format must be according to the SCIM notation. The supported attributes that can be defined in the policy are listed in the **Supported Attributes** section below this table. **Note** If the `user.attributes` is used with the "=" operator, it supports only one attribute. For more attributes, use the "IN" operator adding each attribute separately. **Note** If you use the `password` attribute, you must also add the following two attributes: • `active` • `urn:ietf:params:scim:schemas:extension:sap:2.0:User:status` Enter the attributes separated by comma without using a space. **Example** `active,urn:ietf:params:scim:schemas:extension:sap:2.0:User:status`

Attributes	Value
Deprecated `user.excludedAttributes`	**Note** The `user.excludedAttributes` attribute is deprecated. If you have a policy configured with the `user.excludedAttributes` attribute exchange the `user.excludedAttributes` with the `user.attributes` attribute in combination with the "NOT IN" operator. If the policy is configured with the `user.attributes` attribute used with the "=" operator, it supports only one attribute. For more attributes, use the "IN" operator adding each attribute separately.

Restriction

The "NOT IN" operator can be used only with the `user.attributes` attribute. Do not use "NOT IN" in combination with other attributes or groups.

Expand the **Supported Attributes** section below to see the user attributes that can be configured in the authorization policy:

Supported Attributes

Core Schema

- `name.givenName`
- `name.familyName`
- `userName`
- `displayName`
- `addresses.country`
- `addresses.streetAddress`
- `addresses.streetAddress2`
- `phoneNumbers.value`
- `phoneNumbers.verified`
- `emails.value`
- `emails.verified`
- `password`

Note

For the attributes defined in the core schema, the Schema URI notation `[urn:ietf:params:scim:schemas:core:2.0:User]` is not needed, for all the other attributes, schema URI and the attribute name is required. For example: `user.attributes IN displayName,addresses.country,emails.value;`

EnterpriseUuser Resource Schema

- `costCenter`
- `organization`
- `division`
- `department`

> ⓘ Note
>
> All Enterprise user resource schema attributes require the schema URI urn:ietf:params:scim:schemas:extension:enterprise:2.0:User and the attribute name.
>
> For example: `user.attributes IN urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:costCenter, urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:organization;`

SAP extension schema

- `userUuid`
- `validFrom`
- `validTo`

> ⓘ Note
>
> All SAP extension schema attributes require the schema URI urn:ietf:params:scim:schemas:extension:sap:2.0:User and the attribute name. For example: user.excludedAttributes=urn:ietf:params:`scim:schemas:extension:sap:2.0:User:userUuid, urn:ietf:params:scim:schemas:extension:sap:2.0:User:validFrom;`

Custom Defined Schema

All custom schema defined attributes require a fully qualified attribute name. For example: `user.attributes=urn:sap:cloud:scim:schemas:extension:custom:2.0:MyCustomSchema:CustomString`

Groups of type `Authorization Policy` with names containing the names of the authorization policies are also created in the administration console. You can't delete these groups via the *Groups* section. The groups are related to the authorization policies, and when you delete a policy, the respective group is also removed.

> ⚠ Restriction
>
> You need both read and update access rights to be able to update a field in the administration console. If you can't see a field because of a policy restriction, this field remains also disabled for editing even if update rights are granted to you.

> → Remember
>
> To edit a custom schema custom attribute via the administration console, `users.MANAGE_USERS` without restriction is needed. If the policy has a restriction on the `users.MANAGE_USERS` base policy, you won't be able to edit the custom schema custom attribute.

> ### Example
>
> Michael Adams is an administrator at retail company A. He is located at the company's head office in Germany and as chief administrator of the company he has all the authorizations in the administration console for SAP Cloud Identity Services. Dona Moore is also an administrator at company A. She is responsible for the branch office in the USA. As such she needs to have access only to the users in the USA. Michael Adams creates an authorization policy for read-users access and assigns Dona Moore to that policy. He also removes the *Read Users* and *Manage Users* authorizations that Dona has as an administrator. As a result, now, when Dona accesses the *User Management* section of the administration console, she sees only the users that are located in the USA. All the other users are hidden.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the list item for the administration console.
4. Under the tab *Authorization Policies*, select a custom authorization policy.

   > ### Note
   >
   > Type the name or package in the search field, filter the names or packages, or choose the policy from the list.
   >
   > If you don't have a created authorization policy in your list, you can create one. For more information, see Create an Authorization Policy [page 2247].

5. Choose the *Edit* button.
   a. To customize the rules of the authorization policy, choose the *Rules*.
   b. To assign administrator or administrators to this policy, choose the *Assignments* tab.
6. Save your changes.

1.7.8.4.2 Configure Technical User Authorizations

Configure granular access control for the technical users in the SAP Cloud Identity Services administration console.

Prerequisites

You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Tenant administrators can assign specific authorizations to end users or administrators, allowing them to create, read, update, delete technical users, or a combination of these operations in the administration console of SAP Cloud Identity Services. The distribution of responsibilities enables the authorized users (not necessarily administrators) within your organization to concentrate on their specific areas of access and expertise.

The following authorization policies related to technical users are available in the administration console application under the package name *technical_users*. These policies are non-editable, meaning you can't add or delete rules (i.e., restrictions). You can only assign users to the authorization policy.

Authorization Policy	Description
`CREATE_TECHNICAL_USERS`	Allows users only to create technical users.
`READ_TECHNICAL_USERS`	Allows users only to view the technical users and the information about them. The user with this policy can see the tile *Technical Users* in the administration console for SAP Cloud Identity Services.
`UPDATE_TECHNICAL_USERS`	Allows users only to update the technical users.
`DELETE_TECHNICAL_USERS`	Allows users only to delete the technical users.
`MANAGE_TECHNICAL_USERS`	Allows users to manage the technical users. The `MANAGE_TECHNICAL_USERS` policy

Authorization Policy	Description
	combines the authorizations from the other policies: `CREATE_TECHNICAL_USERS`, `READ_TECHNICAL_USERS`, `UPDATE_TECHNICAL_USERS`, and `DELETE_TECHNICAL_USERS`

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the *Administration Console*.
4. Under the *Authorization Policies* tab, search for the authorization policy and select it.

   You can type the policy name or package in the search field, filter the policy by package type, or choose it directly from the list.

   The policy names follow this convention: `<action>_<functionality>_<resource>`, for example: *MANAGE_TECHNICAL_USERS*
5. Under the *Assignments* tab, choose *Add* and add a user.

   To assign a user to multiple authorization policies, repeat steps 4 and 5 as necessary. Alternatively, you can combine multiple policies by creating a new policy of type *Customer Package* and assign the user to all included policies at once. For more information, see Combine Authorization Policies [page 2249].

Results

When an authorization policy is assigned to a user, a user group named after the policy is also assigned to that user. For example, if a user is assigned the `MANAGE_TECHNICAL_USERS` policy, they become members of the following user group: `technical_users - MANAGE_TECHNICAL_USERS`

Next Steps

Administrators with assigned technical user authorizations can create and manage the technical users. See Managing Technical Users [page 2329].

1.7.8.4.3 Configure Group Authorizations

Configure granular access and control over the groups in the administration console of SAP Cloud Identity Services.

Prerequisites

You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Once it's enabled, it may take up to 60 seconds before the administrator can see the *Authorization Policies* tab when accessing the administration console application. Under the "groups" package the following base policies are visible: `CREATE_GROUPS` , `DELETE_GROUPS`, `MANAGE_GROUPS`, `READ_GROUPS`, and `UPDATE_GROUPS`. You can add users to these policies so that they can have the rights these policies give.

> ⓘ Note
>
> The Manage Groups authorization overrides all "groups" package policies. If you want to configure access to the groups based on policies, you must remove the Manage Groups authorization. For more information, see Edit Administrator Authorizations [page 2309].

You can restrict access on the basis of the base policies or you can use a custom policy, restricting the groups on the basis of the `group.name`, `group.displayName`, `group.type`, or `group.applicationId` attributes.

Group Attributes

Attributes	Value
`group.name`	The name of the group.
`group.displayName`	The display name of the group.
`group.type`	The type of the group. The supported values are: • `userGroup` • `authorization` • `deepLinkActivationPermission`
`group.applicationId`	The ID of the application which is the unique identifier of that application configured in Cloud Identity Services.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the list item for the administration console.
4. Under the tab *Authorization Policies*, you can choose the following options:

Use base policy	1. Filter the policies by the "groups" package. **Note** This limits the policies to the following: *CREATE_GROUPS* , *DELETE_GROUPS*, *MANAGE_GROUPS*, *READ_GROUPS*, and *UPDATE_GROUPS*. 2. Select a policy from the list. 3. Choose the *Add* button. 4. Select the user or users and choose Add.
Use custom policy	1. Select a custom authorization policy. **Note** If you don't have an authorization policy in your list, you can create a restriction policy using the `groups.DELETE_GROUPS`, `groups.READ_GROUPS`, `groups.UPDATE_GROUPS` parameters. For more information about how to create a custom authorization policy, see Create an Authorization Policy [page 2247]. 2. Choose the *Edit* button.

3. To customize the rules of the authorization policy, choose *Rules*.
    1. For each **USE** statement of the selected authorization policy, add a **RESTRICT** condition with `Value`, choose one of the available attributes, an operation, and enter a value.
    2. Save your changes.
4. To assign user to this policy, choose the *Assignments* tab and add users from the list.

    > **Restriction**
    >
    > If the user is a tenant administrator you must remove the *Manage Groups* role from that user, otherwise they won't be able to see and have control (read, update or delete) over the groups for this policy.

5. Save your changes.

    > **Note**
    >
    > Now the assigned users can see and have control over the groups with that are specified in the custom policy.

Task overview: Configure Authorizations Based on Policies [page 2311]

1.7.8.4.4 Configure Policy Authorizations

Configure granular access and control over the authorization policies in the administration console of SAP Cloud Identity Services.

Prerequisites

- You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].
- You need the following authorization policies to fully use Authorization Management in the *Authorization Policies* tab. See Assign Authorization Policies [page 2363].

Authorization Policies	Description
`READ_POLICIES`	Read the authorization policies
`READ_GROUPS`	Read the policy assignments
`READ_USERS`	Display users on the *Assignments* tab
`READ_APPLICATION`	Read the application

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Once it's enabled, it may take up to 60 seconds before the administrator can see the *Authorization Policies* tab when accessing the administration console application. Under the *policies* package the following base policies are visible: `CREATE_POLICIES` , `DELETE_POLICIES`, `MANAGE_POLICIES`, `READ_POLICIES`, and `UPDATE_POLICIES`. You can add users to these policies so that they can have the rights these policies give.

You can restrict access on the basis of the base policies or you can use a custom policy, restricting the authorization policies on the basis of the `policy.name` and `policy.applicationId` attributes.

Policy Attributes

Attributes	Value
`policy.name`	The name of the authorization policy.
`policy.applicationId`	The ID of the application which is the unique identifier of that application configured in SAP Cloud Identity Services.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the list item for the administration console.
4. Under the tab *Authorization Policies*, select an authorization policy with the *policy* package.

   > ⓘ Note
   >
   > Type the name or package in the search field, filter the names or packages, or choose the authorization policy from the list.
   >
   > If you don't have a created authorization policy in your list, you can create one. For more information, see Create an Authorization Policy [page 2247].

5. Expand the authorization policy you want to assign to an administrator.
6. Choose *Add* on the *Assignments* tab.
7. Select the user you want to assign and choose *Add*.

Task overview: Configure Authorizations Based on Policies [page 2311]

1.7.8.4.5 Configure Application Authorizations

Configure granular access and control over the applications in the administration console of SAP Cloud Identity Services.

Prerequisites

You have enabled the authorizations based on policies option in the admin console for SAP Cloud Identity Services. See Configure Authorizations Based on Policies [page 2311].

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Once it's enabled, it may take up to 60 seconds before the administrator can see the *Authorization Policies* tab when accessing the administration console application. Under the "applications" package the following base policies are visible: `CREATE_APPLICATIONS` , `DELETE_APPLICATIONS`, `MANAGE_APPLICATIONS`, `READ_APPLICATIONS`, and `UPDATE_APPLICATIONS`. You can add users to these policies so that they can have the rights these policies give.

> ⓘ Note
>
> The Manage Applications authorization overrides all "applications" package policies, while the Manage Users authorization overrides the `READ_APPLICATIONS` policy only. If you want to configure access to the applications based on policies, you must remove the Manage Applications and Manage Users authorizations. For more information, see Edit Administrator Authorizations [page 2309].

You can restrict access on the basis of the base policies or you can use a custom policy, restricting the applications on the basis of the `application.organization` attribute.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the list item for the administration console.

4. Under the tab *Authorization Policies*, you can choose the following options:

Use base policy	1. Filter the policies by the "applications" package. **Note** This limits the policies to the following: *CREATE_APPLICATIONS* , *DELETE_APPLICATIONS*, *MANAGE_APPLICATIONS*, *READ_APPLICATIONS*, and *UPDATE_APPLICATIONS*. 2. Select a policy from the list. 3. Choose the *Add* button. 4. Select the user or users and choose Add.
Use custom policy	1. Select a custom authorization policy. **Note** If you don't have a custom authorization policy in your list, you can create a restriction policy using the `applications.CREATE_APPLICATIONS`, `applications.MANAGE_APPLICATIONS`, `applications.DELETE_APPLICATIONS`, `applications.READ_APPLICATIONS`, `applications.UPDATE_APPLICATIONS` parameters. For more information about how to create a custom authorization policy, see Create an Authorization Policy [page 2247]. 2. Choose the *Edit* button. 3. To customize the rules of the authorization policy, choose *Rules*. 4. To assign user to this policy, choose the *Assignments* tab and add users from the list. **Restriction** If the user is a tenant administrator you must remove the *Manage Applications* and *Manage Users* roles from that user, otherwise they won't be able to see and have control (read, update or delete) over the applications for this policy. 5. Save your changes. **Note** Now the assigned users can see and have control over applications with *Organization ID* specified in the custom policy.

Next Steps

View or edit the *Organization ID* of the application. By default, all applications are in the *global* organization. For more information, see Edit Applications [page 1929]

Task overview: Configure Authorizations Based on Policies [page 2311]

1.7.8.4.6 Configure Provisioning Authorizations

Configure granular access control for the Identity Provisioning systems and logs in the SAP Cloud Identity Services administration console.

Prerequisites

- You have enabled the *Policy-Based Authorizations* option in the SAP Cloud Identity Services admin console. See Configure Authorizations Based on Policies [page 2311].
- Your tenant administrator has the following authorizations: *Manage Application*, *Manage Groups* and *Read Users*.

Context

> ⚠ Restriction
>
> This feature is relevant only for the Administration Console application.

> → Remember
>
> If your tenant has been migrated to a new region, you need to configure your authorizations based on policies again.

Tenant administrators can assign specific authorizations to users, allowing them to access only source systems, target systems, proxy systems, provisioning logs, or any combination of these. The distribution of responsibilities enables authorized users (not necessarily administrators) within your organization to concentrate on their specific areas of access and expertise.

The following authorization policies related to provisioning are available in the Administration Console application under the package name *provisioning*. These policies are non-editable, meaning you cannot add or delete rules (i.e., restrictions). You can only assign users to the authorization policy.

Authorization Policy	Description
MANAGE_PROVISIONING_SOURCES	Allows users to manage source systems only. This includes creating systems, managing properties, transformations and certificates, as well as running and scheduling provisioning jobs and viewing notifications.
MANAGE_PROVISIONING_TARGETS	Allows users to manage target systems only. This includes creating systems, managing properties, transformations and certificates, as well as viewing notifications.
MANAGE_PROVISIONING_PROXIES	Allows users to manage proxy systems only. This includes creating systems, managing properties, transformations and certificates, as well as viewing notifications.
MANAGE_PROVISIONING_LOGS	Allows users to manage provisioning job logs and real-time provisioning logs, as well as viewing notifications.

> **Note**
>
> The *Manage Identity Provisioning* role, provides full access to all configurations and functionalities of the service. After the implementation of the granular access control on December 3, 2024, users assigned to this role will retain their full access, regardless of any policies assigned.

To assign users to one or more authorization policies, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose *Applications*.
3. Under *System Applications*, choose the *Administration Console*.
4. Under the *Authorization Policies* tab, search for the authorization policy and select it.

   You can type the policy name or package in the search field, filter the policy by package type, or choose it directly from the list.

   The policy names follow this convention: `<action>_<functionality>_<resource>`, for example: *MANAGE_PROVISIONING_LOGS*
5. Under the *Assignments* tab, choose *Add* and add a user.

To assign a user to multiple authorization policies, repeat steps 4 and 5 as necessary. Alternatively, you can combine multiple policies by creating a new policy of type *Customer Package* and assign the user to all included policies at once. For more information, see Combine Authorization Policies [page 2249].

Results

When an authorization policy is assigned to a user, a user group named after the policy is also assigned to that user. For example, if a user is assigned the MANAGE_PROVISIONING_LOGS policy, they will become members of the following user group: MANAGE_PROVISIONING_LOGS - provisioning - Administration Console.

Upon logging in at either `https://<tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin`, the user will have access specifically to the provisioning logs in the SAP Cloud Identity Services administration console and no other areas.

1.7.9 Managing Technical Users

As a user with assigned special policy authorizations, you can manage the technical users in the administration console for SAP Cloud Identity Services.

Prerequisites

- The authorizations based on policies option in the admin console for SAP Cloud Identity Services is enabled. See Configure Authorizations Based on Policies [page 2311].
- You are assigned with the respective technical user authorizations. For more information, see Configure Technical User Authorizations [page 2318].

Context

Technical users in SAP Cloud Identity Services are non-human identities that enable automated system-to-system communication and integration. These users are created and managed in the administration console via the *Technical Users* tile that appears under *Users & Authorizations*.

1.7.9.1 Create a Technical User

As a user with assigned special policy authorizations, you can create a technical user in the administration console for SAP Cloud Identity Services.

Prerequisites

- The authorizations based on policies option in the admin console for SAP Cloud Identity Services is enabled. See Configure Authorizations Based on Policies [page 2311].
- You are assigned with a `MANAGE_TECHNICAL_USERS` or `CREATE_TECHNICAL_USERS` authorization policy. For more information, see Configure Technical User Authorizations [page 2318].

Context

You create the new technical user with a *Display Name* as a minimal requirement. The owner's first name, last name, and email are optional and can be added or edited later. The technical user automatically receives an email address, and a SCIM ID that can't be edited.

Later, if you are assigned with the required authorization policy you can edit the technical user attributes, or delete it. For more information, see Configure Technical User Authorizations [page 2318].

To create a technical user, use the following procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose *Users & Authorizations* > *Technical User*.
3. Press *Create*.
4. Fill in the required fields in the dialog box.

Field	Required
Display Name	Yes
Owner First Name	No
Owner Last Name	No
Owner Email	No

5. Press *Create*

Results

If the operation is successful, the system displays the message: `Technical user created`.

Users [page 509]

1.7.9.2 Manage Technical User Details

As a user with assigned special policy authorizations, you can manage the technical user details and in the administration console for SAP Cloud Identity Services.

Prerequisites

- The authorizations based on policies option in the admin console for SAP Cloud Identity Services is enabled. See Configure Authorizations Based on Policies [page 2311].
- You are assigned with the respective technical user authorizations, depending on the tasks you need to perform. For more information, see Configure Technical User Authorizations [page 2318].
- There is an existing technical user in the tenant of SAP Cloud Identity Services.

Context

You can view or edit the technical user details, configure authentication, or delete the technical user.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose *Users & Authorizations* > *Technical User*.
3. Select the technical user from the list on the left whose details you want to edit.
4. **Optional:** Under *Details tab* > *General Information* > *Edit* > *choose , change or add new information in the fields* > *Save*.

5. **Optional:** Under *Details tab* > *Client ID*, view and manage the *Client ID* information and status. The *Client ID Lock* option is disabled by default. When enabled, the client ID locks after 5 failed logon attempts using secrets. We recommend you to enable this feature in cases when the client ID secrets are automatically generated.
6. **Optional:** Under *Details tab* > *Configure Authentication*, manage the *Certificates* or *Secrets* that are used for authenticating the client and for API authentication.
7. **Optional:** Under the *Groups tab* > *Assign* > *assign a group from the list* > *Assign*.

1.7.10 Managing Agents

Agent identities automatically appear in SAP Cloud Identity Services after you deploy agents. You can use SAP Cloud Identity Services to review and manage access to these agents.

> ⚠ Caution
>
> This page is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available to users outside of this program.

When you deploy an agent in your SAP landscape, the system automatically registers it in SAP Cloud Identity Services. The agent appears in the *Users & Authorizations* area of the administration console. Assistants, higher-level AI entities that orchestrate one or more agents, also appear in this area and are managed in the same way. From there, you can control which users or groups can invoke the agent. You can't create or delete agent or assistant registrations manually. Nor can you change the agent's authorized API scope. The agent's authorizations are defined by its developer and are read-only for administrators.

Assistants and the agents they invoke are separate registered identities. If an assistant invokes one or more agents, assigning a user to the assistant does not automatically grant them access to those agents. You must assign the user to the assistant and to each agent it invokes separately. If any assignment is missing, the user receives an authorization error when the assistant attempts to invoke the unassigned agent, even if the user has access to all the other entities. When planning access for a user, identify the full chain of entities they need to reach and assign them to each one.

Controlling access to an agent has direct downstream consequences. When you assign a user or group to an agent, you grant those users the right to invoke it. After invocation, the agent acts within the bounds of both its own scoped authorization policies and the invoking user's authorizations in the connected back-end systems. The agent can only call the APIs it was designed to use, and those calls are further limited by what the user is permitted to do in the target application. A user can't use an agent to perform an action that their authorizations wouldn't otherwise allow, and the agent can't access APIs beyond its defined scope regardless

of the user's permissions. Assigning access to an agent is a security decision. It determines not only who can use the feature, but also who can trigger actions in downstream systems through it.

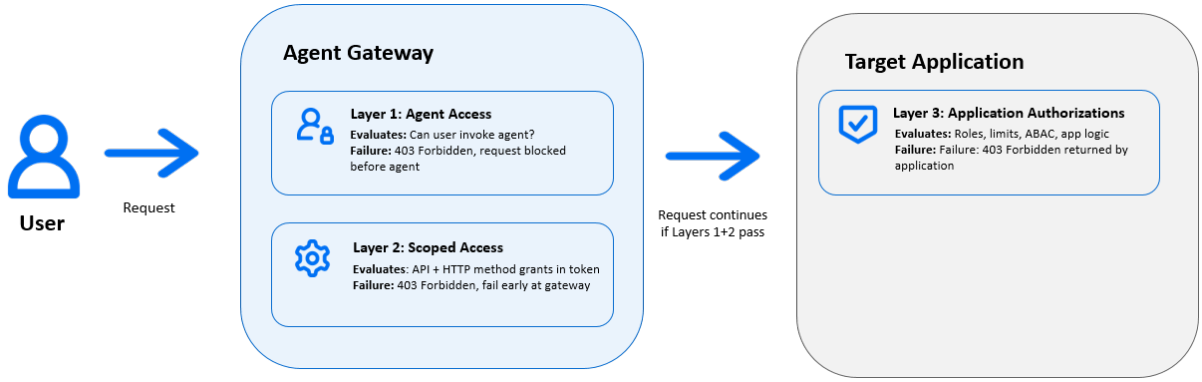
Agent Authorization Policies

Three layers of authorization govern access to and through an agent. The system enforces each layer at a different point in the request path.

The layers are:

1. **Agent access**: whether the requesting user has permission to invoke the agent at all. The system performs this check at the agent gateway on every request. The system automatically generates the policy when you deploy the agent, based on its metadata. The policy appears under the *Authorization Policies* tab of the agent's application entry in the administration console. You can restrict or extend this policy by deciding which users and groups can use the agent.
2. **Scoped access**: whether the agent has permission to call a specific API with a specific HTTP method. The system also enforces this check at the agent gateway, based on grant permissions defined in the agent's authorization token. This check ensures the agent is limited to the API surface it was designed to use, regardless of the invoking user's broader permissions.
3. **Application authorizations**: whether the specific action is permitted by the target application's own authorization logic, for example, ABAP role checks, instance limits, or attribute-based controls in SAP S/4HANA. The target application itself performs this check and returns a 403 response if the action is not permitted. This layer is not configurable in SAP Cloud Identity Services.

The system automatically generates baseline policies for layers one and two from the agent's metadata at deployment time. You can review and adjust these policies in the *Authorization Policies* tab of the agent's application entry. The target application always controls layer three.

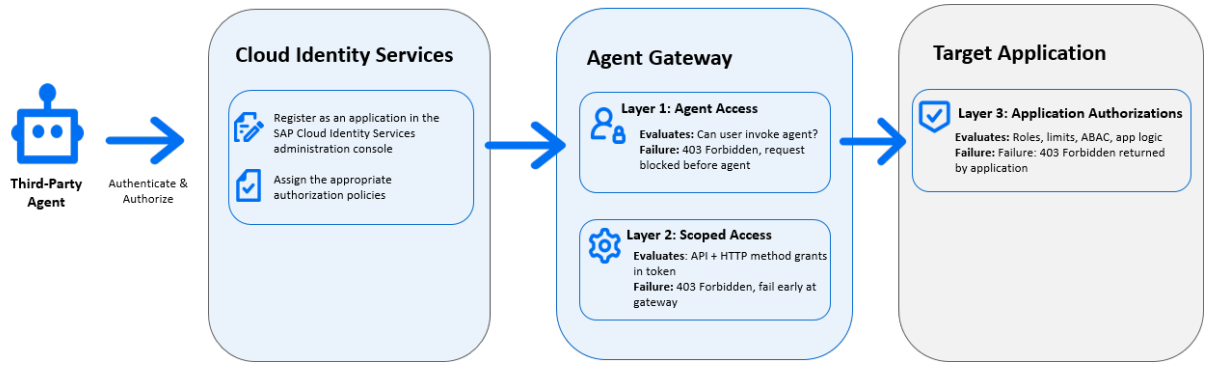


Three Layer Authorization

Agent Identity for Third-Party Tools

Third-party AI tools (external agents not built or deployed by SAP) can also access SAP systems through the agent gateway. To connect a third-party agent, register it as an application in the SAP Cloud Identity Services administration console and assign the appropriate authorization policies. The same three-layer access model applies. The agent must be permitted at the gateway, must have scoped access to the APIs it requires, and its actions remain subject to the target application's own authorization checks.

After you register a third-party agent, it authenticates to the agent gateway using the credentials configured in its application entry in SAP Cloud Identity Services. You can then assign access policies to control which users can invoke the third-party agent and which API operations it is authorized to perform.



Third-Party Agent Authorization Architecture

Review Agent Authorizations [page 2336]
: After agents are deployed, they arrive in your system with the authorizations the developer created for them. Before you enable access to the agent, review its authorizations and decide whether the agent conforms to your authorization policies.

Enable Users to Access Agents [page 2338]
: Assign users to agents to grant users the right to invoke them. You can assign individual users or multiple users with user groups.

Enable Access to Agents for the SAP Early Adopter Care Program [page 2341]
: For the SAP Early Adopter Care (EAC) program, the SAP-managed provisioning jobs create application groups for the Joule agents. Assign these groups to users to enable them to use these agents.

1.7.10.1 Review Agent Authorizations

After agents are deployed, they arrive in your system with the authorizations the developer created for them. Before you enable access to the agent, review its authorizations and decide whether the agent conforms to your authorization policies.

Context

> ⚠ Caution
>
> This page is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available to users outside of this program.

Each agent arrives in your system with a fixed authorization scope, that is, the APIs it is permitted to call at the agent gateway, and whether the permission for each is read or write. This scope is defined by the agent's developer and is read-only for administrators. You can't modify it in SAP Cloud Identity Services. Your role is to evaluate whether the scope is acceptable before you assign any users to the agent. Even if the scope appears broad, actions are also constrained at runtime by the invoking user's own permissions in the target application. That constraint isn't visible here and should not be relied on as a substitute for a careful scope review.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Agents* tile.

   The system displays a list of the agents in the tenant.
3. Choose an agent from the list on the left to view its details.
4. Choose the *Authorizations* tab.
5. Review the authorizations of the agent.

   The *Authorizations* tab shows the agent's scoped access as a list of policies, grouped by target application. Each row names an API by its technical identifier and shows whether the permission is Read or Write.

Because the API names are technical identifiers, you may need to look up what each API does before you can evaluate the scope meaningfully. Use the following questions to guide your evaluation.

Review Guidance

Question	Guidance
Does the scope match the agent's purpose?	An agent designed for read-only reporting should not require write access. A scope broader than the agent's stated function warrants further investigation before you proceed.
Does the scope include write access?	Write access can create or modify data in the target system. Confirm that these operations are necessary for the agent's function and that the risk is acceptable in your environment.
Do the APIs cover sensitive data or critical processes?	Even read-only access to APIs that expose personal data, financial records, or privileged configuration may require additional justification before you grant access.
Is the API surface proportionate?	A scope covering many unrelated APIs may indicate the agent was provisioned with more access than it needs. Apply the principle of least privilege when assessing whether to proceed.
Does the scope cover multiple target systems?	The authorization list may include entries from more than one target application. Review each application group independently. Write access in one application doesn't justify write access in another.

Next Steps

Use the authorization information to determine which users should have access to this agent. The agent can only call the APIs defined in its authorization scope, and the user's own authorizations in the target application further limit what the agent can do on their behalf. The Agent Gateway also monitors agents and their requests. If the agent's authorization scope is broader than you want to allow in your environment, consider these options:

- Don't assign any users to the agent. As long as no user is assigned, no one can invoke the agent, regardless of how the landscape is configured. This gives you as the IAM administrator full control.
- For line-of-business agents, consider reducing the authorizations assigned to the users in the target system. Discuss the situation with the landscape administrator in your organization. The landscape administrator enables the agent for your tenant in SAP for Me. They can determine to which systems the agent has access.
- For custom agents, discuss the situation with the developer of the agent within your organization. Then assign users to the agent only after reviewing and accepting its authorization scope.

If this agent is invoked by an assistant, repeat this review for the assistant and every other agent in the chain before assigning any users. Access assignments are not inherited across the chain. For more information about how the chain works and how to plan assignments, see Managing Agents [page 2333].

Task overview: Managing Agents [page 2333]

Related Information

Enable Access to Agents for the SAP Early Adopter Care Program [page 2341]
Identity and Access Management for Joule [page 580]
Agents [page 511]

1.7.10.2 Enable Users to Access Agents

Assign users to agents to grant users the right to invoke them. You can assign individual users or multiple users with user groups.

Prerequisites

> ⚠ Caution
>
> This page is still work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program are not available to users outside of this program.
>
> See also Enable Access to Agents for the SAP Early Adopter Care Program [page 2341].

Before you begin, ensure the following are in place:

- The agent is deployed and registered in SAP Cloud Identity Services. Agents appear automatically in the *Users & Authorizations* area after deployment. You can't register them manually.
- The users or user groups you want to assign already exist in SAP Cloud Identity Services. You can't create users or user groups from within this procedure.
  For more information, see Managing Users [page 2342] or Managing Groups [page 2393].
- You're assigned an administrator role with the *Manage Users* or *Manage Groups* authorizations in the SAP Cloud Identity Services administration console.
  For more information, see Add Administrators [page 2303].

Context

This task configures the first of three authorization layers that govern agent access: whether a user can invoke the agent. The agent gateway enforces this check on each incoming request before the agent runs. For an overview of all three layers and how they interact, see Managing Agents [page 2333].

Assigning a user or user group to an agent does not expand that user's permissions in the connected back-end systems. After invocation, the agent acts strictly within the bounds of the invoking user's authorizations. A user can't use an agent to perform an action that their authorizations wouldn't otherwise allow.

Access assignments are not inherited. If an assistant invokes one or more agents, assigning a user to the assistant does not automatically grant them access to those agents. You must assign the user to the assistant and to each agent it invokes separately. If any assignment is missing, the user receives an authorization error when the assistant attempts to call the agent.

You can assign access to individual users or to user groups. Assigning user groups is the recommended approach for most scenarios. Group-based access remains consistent as your user base changes: adding or removing a user from the user group automatically updates their agent access without any change to the agent's configuration. Assign access to individual users only when access is specific to one person and isn't expected to extend to others.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Agents* tile.
3. Choose an agent from the list on the left.

   The system displays a list of the agents in the tenant.
4. Choose the *Access* tab.
5. Choose the *Users* or *Groups* tab and then choose *Manage Access*.
6. Add users or user groups to the agent. You have the following options:
   - Select users or groups from the list.
   - Search for users or groups.
     - *Starts With*: (default) Returns only entities that start with the entered value.
     - *Contains*: Returns all entities that contain the entered value. This option may take longer to process.
7. Choose *Review Changes*.
8. Save your changes.

Results

The selected users and members of the selected user groups can now invoke the agent. The change takes effect the next time the user gets a token.

Example: Granting a Team Access to a Joule Assistant and Its Agents

Donna Moore's organization has deployed a Joule assistant for financial analysts in SAP S/4HANA. The assistant invokes two agents: a report generation agent and a data retrieval agent. She wants to grant the entire finance team access to all three.

Before she starts, she confirms that a user group for the finance team already exists in SAP Cloud Identity Services. For example, `Joule_Finance_Analysts`. If the user group doesn't yet exist, she creates it first.

Because access is not inherited, Donna must perform this procedure once for each entity: the assistant and each of its agents. She performs the following steps three times, selecting a different entity each time.

To assign the user group to the agent:

1. In the administration console, Donna goes to *Users & Authorizations* and chooses the *Agents* tile.
2. She selects the financial reporting agent from the list.
3. She chooses the *Access* tab, then the *Groups* tab, and then chooses *Manage Access*.
4. She searches for `Joule_Finance_Analysts`, selects it, chooses *Review Changes*, and then saves.

After Donna completes all three assignments, members of `Joule_Finance_Analysts` can invoke the assistant and the agents it calls. If Donna assigns the group to the assistant but omits one of the agents, users will receive an authorization error when the assistant attempts to call that agent.

When a new analyst joins the team, Donna adds them to the user group `Joule_Finance_Analysts` in SAP Cloud Identity Services. Donna doesn't need to modify the access configuration of the assistant or either agent. When an analyst transfers to another department, removing them from the group revokes their access to all three entities at once.

Each analyst can use the assistant and agents only to perform actions that their own SAP S/4HANA authorizations permit. Assigning the group doesn't grant any additional permissions in the back-end system.

Identity and Access Management for Joule [page 580]
Agents [page 511]

1.7.10.3 Enable Access to Agents for the SAP Early Adopter Care Program

For the SAP Early Adopter Care (EAC) program, the SAP-managed provisioning jobs create application groups for the Joule agents. Assign these groups to users to enable them to use these agents.

Prerequisites

> ⚠ Caution
>
> This page is still a work in progress. This page contains information about product features that are part of an SAP Early Adopter Care (EAC) program. Products or features that are part of an EAC program aren't available to users outside of this program.

Before you begin, ensure the following are in place:

- SAP-managed provisioning jobs have completed successfully and agent authorization groups are available in SAP Cloud Identity Services.
  See also Set Up Identity and Access Management.
- The users you want to assign already exist in SAP Cloud Identity Services.
- You are assigned an administrator role with the *Manage Users* or *Manage Groups* authorizations in the SAP Cloud Identity Services administration console.

Context

After SAP-managed provisioning jobs create authorization groups for Joule agents in SAP Cloud Identity Services, you must assign users to these groups to grant them access to specific agents. This task is part of Stage 2 deployment, where users with real identities in SAP Cloud Identity Services can be authorized to use agents alongside the conversational Joule assistant.

Each agent has its own authorization group. Users must be members of an agent's group to see and interact with that agent. Without group membership, users can still access conversational Joule functions but can't use agents.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Groups* tile.
3. Choose a group from the list on the left.

   Agent authorization groups are created by SAP-managed provisioning jobs. You can sort the list by group type to find the correct authorization group.

4. Choose + *Add*.
5. Add users to the group.
6. Save your changes.

Results

Users assigned to the agent authorization group can now access and interact with the agent. The changes take effect immediately. Users may need to refresh their browser session to see newly available agents.

Next Steps

If users can't access the agent after being assigned to its authorization group:

- Verify that the user has a real identity in SAP Cloud Identity Services with a global user ID assigned.
- Confirm that the user has logged in at least once to the connected line-of-business application using SAP Cloud Identity Services as the identity provider.
- Ask the user to sign out and sign back in to refresh their session.

1.7.11 Managing Users

Tenant administrators can manage user accounts via the administration console for SAP Cloud Identity Services, and via APIs.

The user management enables you to create, modify, and delete users and their attributes, and manage the user accounts in the user store of Identity Authentication.

> **Note**
>
> For more information about the users that are authenticated with their corporate credentials from the corporate user store, see Corporate User Store (Neo Environment) [page 2531].

→ Remember

To perform user management operations, you must be assigned an administrator role or roles that include the relevant authorizations for the operation. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

With user management, you can perform the following activities:

Activity	Description	Procedure
Create users	Provision users	Centralized Provisioning with Identity Directory [page 554]
	Integrate your identity and access management solution with Cloud Identity Services API	Identity Directory API
	Create users via a CSV file import in the administration console	Import or Update Users for a Specific Application [page 2348]
	Manually create users via the *Add* option in the administration console (not recommended for mass user creation)	Create a New User [page 2357]
Search users	Search users in the administration console	Search Users [page 2359]
	Search users via API	Identity Directory API
List and edit user details	List a specific user and edit the information about that user via the administration console	List and Edit User Details [page 2361]
	List and update user details via API	Identity Directory API
	Update user details via a CSV file import	Import or Update Users for a Specific Application [page 2348]
	Manage user password via the administration console	• Unlock User Password [page 2380] • Send Reset Password Email [page 2381] • Reset Counter for Email Sending [page 2383] • Set Initial Password [page 2384]
Delete users	Delete users via the administration console	Delete Users [page 2367]
	Delete users programmatically via API	Identity Directory API

Activity	Description	Procedure
Manage the user group assignment	Assign and unassign groups via the administration console	• Assign Groups to a User [page 2409] • Unassign Groups from a User [page 2410]

1.7.11.1 Import CSV File with Full User Profile

As a tenant administrator, you can create new users or update existing ones with all user data, including attributes from a custom schema, via a CSV file upload.

Prerequisites

- You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

With the CSV file, you can import up to 25000 users to create new users or to update existing users. This is the recommended approach for importing user.

> → Remember
>
> The `SCIM ID` serves as the primary identifier if it is found in the CSV file. The users will only be updated, but not created if there are users with a new `SCIM ID`. This process works within the same tenant because the SCIM IDs differ across tenants.
>
> If the `SCIM ID` doesn't exist in the CSV file, the create and update functionality will function as expected, but the administrator won't be able to modify the `username` or `email`.

The attributes can take one of the following types:

Attribute Type	Column Name (Example)	Value (Example)
`multivalued complex`	emails[0].value	michael.adams@example.com
`complex`	name.familyName	Adams
`single value`	displayName	Michael Adams
`multivalue`	urn:sap:cloud:scim:schemas:extension:custom:2.0:CustomSchema:arrayOfStringsAttr	test1;test2

The following attributes must be a valid master data text:

Attribute	Where to find it
`locale`	• administration console - *Master Data Texts tile* > *Language tab* • API - GET `https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_MD_LANGUAGES&locale=en`
`addresses[0].country`	• administration console - *Master Data Texts tile* > *Countries tab* • API - GET `https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_MD_COUNTRIES&locale=en`

Attribute	Where to find it
`urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:department`	• administration console - *Master Data Texts tile* > *Departments tab* • API - GET `https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_MD_DEPARTMENTS&locale=en`
`name.honorificPrefix`	• administration console - *Master Data Texts tile* > *Salutations tab* • API - GET `https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_MD_SALUTATIONS&locale=en`

→ Remember

The CSV file must contain at least the following three columns:

- `userName` or `loginName`
- `emails[0].value` or `mail`
- `name.familyName` or `lastName`

→ Remember

If there is a column with the name of a certain attribute, and you provide a value for that column, the attribute will be updated.

If there is a column with the name of a certain attribute, and you don't provide a value for that column, the attribute will be deleted.

If there is no column with the name of a certain attribute, the value of the attribute remains unchanged.

If the names of the columns are not from the core schema, they must be written with the `urn:attribute name`.

→ Tip

To update the `emails` or `userName` attribute you must provide the `SCIM ID` for the users that you want to update.

ⓘ Note

The user import doesn't assign any special rights or roles to the created or updated users for the specific application.

The CSV file can contain only columns with no spaces between them, with all the attributes whose names are compliant with SCIM specification, plus the attributes from a custom schema that exist in the tenant of Identity Authentication. If you include columns with other attributes, their values in the table are ignored.

If you enter the data in the CSV file as text, you must separate the entries with commas. Beware not to put any spaces before or after the comas. If you enter more than one value in a single entry, separate the values within the entry with semicolons.

Values shouldn't contain semicolons. If there is a semicolon, in the import the value will be split by that semicolon and more than one attribute value will be added.

Depending on your *Logon Alias* configuration in the administration console, you must consider the following:

- If *Email* is required and unique, in the csv file at least one `emails[0].value` must be present and unique.
- If *Login Name* is required and unique, in the csv file at least one `userName` must be present and unique.
- If *Display Name* is required and unique, in the csv file at least one `displayName` must be present unique.

⚠ Restriction

The user import doesn't support the `groups` and `spCustomAttribute1`

You can view all of the supported schemas attributes and their definitions in the administration console of Identity Authentication under schemas. For more information, see Manage Custom Schemas via Administration Console [page 2388].

Example

Sample CSV file:

Sample Code

```
emails[0].value,emails[0].primary,emails[0].type,name.familyName,name.given

To import users into the user store of Identity Authentication, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Press the *Import* button.
4. Choose the *Browse...* button and specify the location of the CSV file.

   > ⓘ Note
   >
   > Use a UTF-8 encoded file with up to 25000 users and an extension `.csv`. If your file contains more than 25000 users, you have to import the user information in iterations within the user number limit.
5. Choose the *Save* button.

   If the operation is successful, the system displays a message with the number of imported and updated users.

Related Information

SCIM Common Attributes

1.7.11.2 Import or Update Users for a Specific Application

As a tenant administrator, you can import new users or update existing ones for a specific application with a CSV file. You can also send activation emails to the users that have not received activation emails for that application so far.

Prerequisites

- You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have uploaded the service provider's metadata or entered the information manually. For more information see, Configure Trust [page 1941].

  > ⓘ Note
  >
  > You need the metadata to configure the trust between the service provider and Identity Authentication, which is in the role of identity provider.

Context

> **Note**
>
> The recommended approach to import users is via a CSV file upload. For more information, see Import CSV File with Full User Profile [page 2344].

By importing new users with a CSV file, you create user profiles without passwords in Identity Authentication. As a result, the users receive emails with instructions how to activate their accounts. After the users set their passwords, they can log on to the application for which they were imported. Based on the user access configuration of the application, the users can log on to other applications connected with the tenant in Identity Authentication.

In addition to the new user import, you can specify existing users in the imported CSV file. You thus define the users to be updated in Identity Authentication.

By specifying existing users in the imported CSV file you can also restrict the access to a specific application via the *Private* options. For more information, see Configure User Access to the Application [page 2025].

> **Note**
>
> The user import does not assign any special rights or roles to the created or updated users for the specific application.

The CSV file can contain only columns with no spaces between them, with the following attributes. If you include columns with other attributes, their values in the table are ignored.

> **Note**
>
> If you enter the data in the CSV file as text, you must separate the entries with commas. Beware not to put any spaces before or after the commas. If you enter more than one value in a single entry, separate the values within the entry with commas and enclose the entry in quotation marks.

CSV Files Attributes

Attributes	Mandatory	Unique	Valid Values	Notes
`status`	Yes	No	• `active` • `inactive`	The *status* column defines whether the user is still active in the system and is able to work with any tenant applications. When a user is deleted, it's rendered inactive. **Note** When a user's password is not set, if you pass a `status` with value `active`, the status of the user will not change to `active`. It will be set to `new`.
`loginName`	No	Yes		Must be a string value of up to 64 characters. You cannot change the email of an existing user.

Attributes	Mandatory	Unique	Valid Values	Notes
`mail`	Yes	Yes		→ Tip For users without valid email addresses or for testing purposes use the `sap-test.de` domain, for example `<username>@sap-test.de`. Do not use any other existing or non-existing domains. Must be a string value of up to 64 characters. Values that are part of the respective exclude list can't be used. For more information, see Restrict User Attributes Values via Exclude Lists [page 2385].
`firstName`	No	No		Must be a string value of up to 64 characters. Values that are part of the respective exclude list can't be used. For more information, see Restrict User Attributes Values via Exclude Lists [page 2385].
`lastName`	Yes	No		Must be a string value of up to 64 characters. Values that are part of the respective exclude list can't be used. For more information, see Restrict User Attributes Values via Exclude Lists [page 2385].

Attributes	Mandatory	Unique	Valid Values	Notes
`language`	No	No		Must be a string value specified by a two or four-letter code in one of the following formats: XX. Otherwise, the activation email is in English.
`validTo`	No	No		Must be a string value in the Zulu format yyyyMMddHHmmss'Z' . The information in the *validFrom* and *validTo* columns can be processed by the service provider to limit user access. It would affect the authentication of the user, though.
`validFrom`	No	No		Must be a string value in the Zulu format yyyyMMddHHmmss'Z' . The information in the *validFrom* and *validTo* columns can be processed by the service provider to limit user access. It would affect the authentication of the user, though.
`userType`	No	No	• public • employee • customer • partner • external • onboardee • alumni	

Attributes	Mandatory	Unique	Valid Values	Notes
`urn:ietf:params:scim:schemas:extension:sap:2.0:User:mailVerified`	No	No	• true • false - the default value	
`spCustomAttribute1`	No	No		
`spCustomAttribute2`	No	No		
`spCustomAttribute3`	No	No		
`spCustomAttribute4`	No	No		
`spCustomAttribute5`	No	No		
`groups`	No	No	The `name` attribute defined in the Group schema (`urn:sap:cloud:scim:schemas:extension:custom:2.0:Group`)	The groups in the *groups* column must be existing. You can't add a user to a user group that is not existing.

Examples

Example

A tenant administrator decides to import three new users (Michael, Julie, Donna) and to update two others (John and Denise) that will use the company's applications. Michael is a member of three groups, namely *Employees*, *Managers*, and *HR*. John and Denise were inactive users that now use tenant's applications. The administrator would also like to update another user (Richard) who currently does not work for the company. To do this, the administrator uploads a CSV file with the following information:

Sample Code

```
status,loginName,mail,firstName,lastName,language,validFrom,validTo,spCustomAttribute1,groups
active,EID00001,michael.adams@example.com,Michael,Adams,en,20110901120000Z,20150901120000Z,Industry,"Managers, Employees, HR"
active,EID00002,julie.armstrong@example.com,Julie,Armstrong,en,20110901120000Z,20150901120000Z,Department,Employees
active,EID00003,donna.moore@example.com,Donna,Moore,de,20110901120000Z,20160901120000Z,Shift,HR
active,EID00004,john.miller@example.com,John,Miller,en,20110901120000Z,20180901120000Z,Unit,IT
active,EID00005,denise.smith@example.com,Denise,Smith,en,20110901120000Z,20140901120000Z,,Administrators
inactive,EID00006,richard.wilson@example.com,Richard,Wilson,en,20110901120000Z,20160901120000Z,,All
```

The administrator receives the following message: `3 users will be created. 3 users will be updated because they already exist. Do you want to continue?`

The users that have not received activation emails will receive such emails, and then can activate their accounts and log on.

Example

A sales company has employed two new people (Michael Adams and Julie Armstrong) in the HR department. The tenant administrator has to import these two new employees that will use the company's applications. Michael and Julie are members of the groups **Employees** and **HR**. To do this, the administrator uploads a CSV file with the following information:

Sample Code

```
status,mail,firstName,lastName,groups
active,michael.adams@example.com,Michael,Adams,"Employees, HR"
active,julie.armstrong@example.com,Julie,Armstrong,"Employees, HR"
```

Six months later, Julie is promoted as HR Manager, while Michael moves to the Sales department. The tenant administrator has to update the profiles of Michael and Julie to represent the changes. Julie remains in the current groups and has to be included in the **Managers** group. Michael has to be removed from the **HR** group, and to be included in the **Sales** group. To do this, the administrator uploads a CSV file with the following information:

Sample Code

```
status,mail,firstName,lastName,groups
active,michael.adams@example.com,Michael,Adams,"Employees, Sales"
active,julie.armstrong@example.com,Julie,Armstrong,"Employees, HR,
Management"
```

→ Remember

When tenant administrators must update a user via a CSV file, they must include the new information, and repeat the information that remains unchanged.

If you, as a tenant administrator, include only the new information, the information that is not repeated will be deleted.

In this example, the administrator imports Michael with the **Employees** group, and Julie with the **Employees** and **HR** groups in the new table.

To import users for an application into Identity Authentication, and to send activation emails, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Choose the *Import Users* tile.

   This operation opens the *Import Users* page.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Under *Upload CSV File*, choose the *Browse...* button and specify the location of the CSV file.

> ### Note
>
> Use a file smaller than 100 KB and with an extension `.csv`. If your file is 100 KB or larger, you have to import the user information in iterations with smaller size files.

5. Choose the *Import* button.

   If the operation is successful, the system displays the message `Users imported or updated`.
6. Choose the one of the following options:

Option	Description
Do nothing	The users are imported or updated for the selected application, but they will not receive activation emails. The activation emails will be sent when you choose *Send Emails* > *Send*.
Repeat steps 1 to 5	The users are imported or updated for the selected application, but they will not receive activation emails. The activation emails will be sent when you choose the *Send* button.
Under *Send Emails* choose the *Send* button	This will send activation emails to all users that are imported for the selected application, but have not received activation emails so far. **Note** The *Send* button is inactive if *Home URL* or SAML 2.0 configuration of the application is missing. You can only import users, but you cannot send activation emails. You need the *Home URL* configured for the specific application to be able to send the activation emails to the imported new users. For more information, see Configure an Application's Home URL [page 1937]. To access the application, the users have to activate their accounts by following the link they receive in the emails.

Related Information

Configure an Application's Home URL [page 1937]
Configure User Access to the Application [page 2025]
List and Edit Groups [page 2400]

Create a Group [page 2398]
Edit Administrator Authorizations [page 2309]
Export Existing Users of a Tenant of Identity Authentication [page 2356]

1.7.11.3 Export Existing Users of a Tenant of Identity Authentication

Prerequisites

- You are assigned the *Manage Users* or *Read Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- (For administrators assigned to a custom authorization policy) You are assigned to `READ_USERS` and `READ_SCIM_SCHEMAS` authorization policies. Otherwise, you won't be able to see and access the *Export Users* tile.

Context

You can export a CSV file containing information of all tenant users in Identity Authentication including the tenant administrators. The CSV file can contain columns with all user supported SCIM attributes. You can filter the user attributes that you want to include in the exported file. The default columns are: *active*, *userName*, *userType*, *emails[0].display*, *emails[0].primary*, *emails[0].type*, and *emails[0].value*.

If the values for the *validTo* and *validFrom* attributes for a specific user aren't in the correct Zulu format yyyyMMddHHmmss'Z', Identity Authentication returns empty values for these attributes in the CSV file.

> → Remember
>
> The `SCIM ID` serves as the primary identifier if it is found in the CSV file. The users will only be updated, but not created if there are users with a new `SCIM ID`. This process works within the same tenant because the `SCIM ID`s differ across tenants.
>
> If the `SCIM ID` doesn't exist in the CSV file, the create and update functionality will function as expected, but the administrator won't be able to modify the username or email.

> ⚠ Restriction
>
> Each multivalued attribute is limited to 3 fixed values, and each custom attribute is limited to 10 values.
>
> For example, if a user in the administration console has more than 3 emails, the export functionality will export only 3 emails. On the other hand, if a user has only one email, then the csv file will show 3 emails, but two of them will be empty.
>
> If you need to export multivalued attributes with more than 3 values, or custom attributes with more than 10 values, you can use the Identity Provisioning service. For more information, see Real-Time Provisioning from Identity Authentication or Provisioning from Source to Target Systems.

> **Note**
>
> If the *active* attribute of a user is FALSE, he or she can't perform any operations on the tenant.

> **Example**
>
> A tenant administrator exports a CSV file with the current users in the system and only the following attributes: *active*, *userName*, *userType*, and *emails[0].value*. As a result, the administrator receives the following information:

active	userName	userType	emails[0].value
TRUE	EID00001	public	michael.adams@example.com
TRUE	EID00002	employee	julie.armstrong@example.com
TRUE	EID00003	partner	donna.moore@example.com
FALSE	EID00004	customer	john.miller@example.com

To export tenant users from Identity Authentication, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Export Users* tile.

   This operation opens the *Export Users* page.
3. Choose the attributes that you want to include in the CSV file.

   The default choice is: *active*, *userName*, *userType*, *emails[0].display*, *emails[0].primary*, *emails[0].type*, and *emails[0].value*.
4. Choose the *Export* button.

1.7.11.4 Create a New User

As a tenant administrator, you can create a new user in the administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

The tenant administrator creates the new user with a minimum set of attributes and can set an initial password.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Press *Add*.
4. Fill in the required fields in the dialog box.

   > ⓘ Note
   >
   > By default the *User Type* field is *Employee*. To change the default setting, choose user type from the drop-down list. The available user types are: *Customer*, *Employee*, *Partner*, *Public*, *External*, *Onboardee*, and *Alumni*.

   Email field can be skipped when *Set initial password* or *Set status active* is selected, and *Email* is configured as not required in the *Logon Alias* view.

   Values for *Email*, *First Name* and *Last Name* that are part of the respective exclude list can't be used. For more information, see Restrict User Attributes Values via Exclude Lists [page 2385].

   > → Tip
   >
   > If email is mandatory, for users without valid email addresses or for testing purposes use the `sap-test.de` domain, for example `<username>@sap-test.de`. Do not use any other existing or nonexisting domains.
5. Select one of the following options:
   - Send activation email - The tenant administrator creates a user with status `New`. The user receives an email with instructions how to activate the user account. After activating the account, the user status changes to `Active`.
   - Set initial password - The tenant administrator creates a user with status `Active` and sets the password for the user.

     > ⚠ Restriction
     >
     > The initial password can be valid between 1 and 365 days depending on the configuration made by the administrator. The default value is 14 days. The user is prompted to reset the password during the first authentication. After the validity of the initial password expires, the user can't log on to the application and must contact an administrator. For more information for more information about how to configure the initial password validity, see Configure Initial Password and Email Link Validity [page 2168].

- Set status active - The tenant administrator creates a user with status `Active`. The tenant administrator does not set an initial password for the user, and the user does not receive an email with instructions how to activate the user account.
  This option can be used in the following scenarios:
  - Identity Authentication acting as identity provider (IdP) proxy
  - certificate authentication

6. Save your entries.

Results

If the operation is successful, the system displays the message: `User added`. Identity Authentication creates the new user and assigns `User ID` (P user) and `Global User ID` (universally unique identifier (UUID) format). The `User ID` field is unique and not editable. The `Global User ID`, on the other hand, is unique, but editable. You can change it via the user management field in the administration console.

Related Information

Configure User Identifier Attributes [page 2149]
Restrict User Attributes Values via Exclude Lists [page 2385]
List and Edit User Details [page 2361]

1.7.11.5 Search Users

As a tenant administrator, you can search for a specific user or users in the administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

You can list all users in the tenant for Identity Authentication or filter your search by *User ID*, *Global User ID*, *Scim ID*, *First Name*, *Last Name*, *Email*, or *Login Name*.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. **Optional:** You can choose one of the following:

   Search Options

List All Users Press *More*	This will expand the list by 20 users. **Note** This option is available only if there are more than 20 users in the tenant.
Unfiltered Search • (default mode) Type your search criteria string in the search field and press the *Enter* key • (when in *Filtered Search* mode) Press *Hide Filters*, type your search criteria string in the search field, and press the *Enter* key	Once the search is completed, the system will list the users whose *User ID*, *Global User ID*, *SCIM ID*, *Email*, or *Login Name* match your search criteria string. In this case the system doesn't include the *First Name* and *Last Name* fields in the search. If you aren't satisfied with the search result, edit your search criteria and repeat the step again.
Filtered Search Press *Show Filters*, type your search criteria strings in at least one of the search fields, and press the *Enter* key	The system checks the search fields simultaneously. Once the search is completed, it will list the users that match the search criteria from all the fields.

4. **Optional:** To configure the user details columns, choose the *Settings* icon and select the columns that you want to see.

Related Information

Edit Administrator Authorizations [page 2309]

1.7.11.6 List and Edit User Details

As a tenant administrator, you can view detailed information about the users in the administration console for SAP Cloud Identity Services. Optionally you can edit this information.

Context

User ID (P user) and *Global User ID* (universally unique identifier (UUID) format) are automatically generated by Identity Authentication at user creation. The `User ID` field is unique and not editable. The *Global User ID*, on the other hand, is unique, and editable. Thus you can use the generated one, or change it with your own one. You can also reuse previous versions of the *Global User ID* for one and the same user.

By default the *User Type* field is *Employee*. The available user types are: *Customer*, *Employee*, *Partner*, *Public*, *External*, *Onboardee*, and *Alumni*.

Last Name and *Email* fields are mandatory.

Vaues for *Email*, *First Name* and *Last Name* that are part of the respective exclude list can't be used. For more information, see Restrict User Attributes Values via Exclude Lists [page 2385].

Display Name can be configured to be mandatory or not. For more information see Configure User Identifier Attributes [page 2149].

Email and *Login Name* can be used as unique identifiers. Be sure to enter unique values if you edit these two fields.

Only administrators with *Manage Tenant Configuration* role can edit the *Email* attribute.

Display Name can be configured to be unique or not. For more information see Configure User Identifier Attributes [page 2149].

If the check box below the *Email* is selected, the `email` of the user is verified. For more information about how to require email verification of the user, see, Enable Email Verification [page 2026].

If the check box below the *Telephone Verified* is selected, the phone of the user is verified. The tenant administrator can select it manually, to mark the phone as verified.

> ⚠ Caution
>
> Be careful when there is no Sinch configuration for the tenant and you manually verify the phone via the administration console. In this case users can't change their phones via the profile page. Make sure to inform the users how to change the phone on the profile page.

User ID, and *Manager Display Name* fields cannot be edited. They are filled automatically by the system.

The *Valid From* and *Valid To* fields are empty if no validity dates are set for the user.

> → Remember
>
> When the *Display Name* is set as unique:
>
> - If the user is created via the User Registration service of the User Management Rest API, and after successful activation of the user, the display name is generated in the following way: *Display Name* is `first_name last_name`.

- If there is already another user with the same display name, the *Display Name* is `first_name last_name user_profile_id`.

The display name can be changed also by the user via the user profile page.

Attributes from Custom Schema

The attributes assigned from custom schema are visible at the bottom of the *Details* tab under a section with the name of the custom schema.

You can also update an attribute by calling the PATCH method of Resource Management API of SAP Cloud Identity Services.

Procedure

1. Find the user whose details you want to view or edit.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Click the user to view his or her details.

   This operation opens the *Details* view.
3. **Optional:** Choose the *Details* tab.
   a. Press the *Edit* button at the top of the page.
   b. Edit the information in the relevant fields and save your changes.

      If the operation is successful, the system displays the message `User <user ID> updated`.

   > ### Note
   >
   > To exit edit mode, press the *Cancel* button.
4. **Optional:** Choose the *Applications* tab, to view details specific for the applications that the user has logged on, and the applications that the user was imported to via a CSV file import.

   > ### Note
   >
   > The tab does not appear if the user hasn't logged on, or wasn't imported to an application via a CSV file import. The tab *Applications* is replaced by *Administration Console* if the user is admin and the only application that they have logged on is the administration console.
5. **Optional:** Choose the *Legal* tab to view audit information about the user, such as the policies accepted, the last log on, and password related information.

   > ### → Remember
   >
   > The *Last Log On* and *Password Login Time* fields are updated once per 24 hours.

   > ### Note
   >
   > The tenant administrators can view a history of the signed **Terms of Use** and **Privacy Policy** documents of the users in the administration console. The information is in the format *<document name><document version><time stamp>*.

> The information about when the user has accepted a particular document is available for documents accepted after May 16, 2018.

6. **Optional:** Choose the *Authentication* tab to manage the two-factor authentication for the user. You have the following options:

Option	Additional Information
User Status	Unblock a User [page 2369]
Authentication > *Password Details*	• Unlock user password. For more information, see Unlock User Password [page 2380]. • Send reset password email. For more information, see Send Reset Password Email [page 2381]. • Reset counter for email sending. For more information, see Reset Counter for Email Sending [page 2383]. • Set initial password to the user. For more information, see Set Initial Password [page 2384]. **Note** Only administrators with *Manage Tenant Configuration* role can set initial password of other administrators.
Authentication > *Multi-Factor Authentication*	If the user has enabled two-factor authentication, you can do the following: • Deactivate the user devices. For more information, see Deactivate User Devices for TOTP Two-Factor Authentication [page 2371]. • Unlock User TOTP Passcode [page 2372].

7. **Optional:** Choose the *User Groups* tab to manage the group assignments of the user.

   You can see the user groups assigned to the user. You have two options:

   - Assign groups. For more information, see Assign Groups to a User [page 2409].
   - Unassign one or more groups that are assigned to the user Unassign Groups from a User [page 2410].

1.7.11.7 Assign Authorization Policies

As an administrator, you can assign authorizations to users.

Prerequisites

- Your application supports authorization policies. Refer to the documentation of your application.
- Your user has administrative permissions in Identity Authentication with the the following authorizations:
  - *Manage Applications*

- *Manage Groups*

  For more information, see Edit Administrator Authorizations [page 2309].
- You have a subscription to SAP Cloud Identity Services. For more information, see SAP Cloud Identity Services.

> **Note**
>
> If your application doesn't have an *Authorization Policies* tab, it doesn't support authorization management.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose the *Applications* tile.
3. Choose your application that supports authorization management. For more information, see the documentation of the application.

   The details page of your application has an *Authorization Policies* tab.
4. Choose the *Authorization Policies* tab.
5. Choose an authorization policy that you want to assign. The administration console opens the *Assignments* pane.
6. Choose *Add*.
7. Select the users that you want to add to the authorization policy and choose *Add*.

   You have added the selected users to an authorization policy. These users are authorized to access and use the resources with the rules and restrictions defined in the authorization policy.

Related Information

Configuring Authorization Policies [page 2244]

1.7.11.7.1 Manage Authorization Policies for a Reuse Service Across Multiple Applications

The authorization data for a reuse service is shared among multiple business applications in the same tenant, ensuring consistent authorization policies across different applications for users logged on to these applications.

Context

A reuse service is consumed by multiple business applications, for example application 1 and application 2. All applications and reuse services can have their own set of authorization policies that are always tied to the application or to the reuse service. For easy maintenance, it is possible to manage the authorization policies of the reuse service in the *Authorization Policies* tab of the application that consumes the reuse services.

When an administrator assigns a user to an authorization policy of the reuse service, the reuse grants this permission regardless of the authorization context of the business application. That means, if the user logs on to application 1 or application 2, the permissions for the reuse service are the same, meaning the authorization policies of the reuse service.

The same is reflected on the administration side. Users assigned to authorization policies of the reuse service can always consume the same content. It doesn't matter whether they have logged on to application 1 or application 2.

If you assign the authorization policies of the reuse service to users of application 1 or 2, you enable these users to access the reuse service. They can simply log on to application 1 or 2 and immediately use the reuse service.

To assign authorization policies of the reuse service to users, take the following steps.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications & Resources*, choose the *Applications* tile.
3. Choose the application that supports authorization management and authorization policies for the reuse service.
4. Choose the *Authorization Policies* tab. You see the list of the authorization policies of your application. Next to the table title, there's a dropdown list where you can select the reuse service. Currently, it displays the name of your application.

   > ⓘ Note
   >
   > If the consuming application doesn't have its own policies, the administration console directly displays the policies of the reuse service instead.

5. Open the drowdown list.
6. Select the reuse service. The table displays the list of the policies that belong to the reuse service.

7. Choose an authorization policy you want to assign. The *Assignments* pane opens.
8. Choose *Add*.
9. Select the users that you want to add to the authorization policy and choose *Add*.

   You have added the selected users to an authorization policy. These users are now authorized to access and use the reuse service with the rules and restrictions defined in the authorization policy.

1.7.11.8 Block or Delete Users Due to Inactivity

Tenant administrator can configure specific user types to be blocked and deleted, or only blocked, or only deleted after a certain period of inactivity.

Context

The users for which blocking can be enabled are of the type:

- *Public*
- *Customers*
- *Partners*
- *Employees*

You can enable the chosen user type or types to be only blocked, or only deleted, or both blocked and deleted after a certain period of inactivity. The period spans from 14 up to 2000 days.

To enable blocking and or deletion, you must choose at least one user type and set at least one period.

After a user has exceeded the set period of inactivity, they will be blocked and their status will be updated on the next sign-in attempt.

You can also configure when the deletion script starts.

> ⓘ Note
>
> If you configure both *Block after* and *Delete after* periods, the *Delete after* period must be longer than the *Block after* period.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Blocking and Deletion* list item.
4. Choose *Edit*.

5. Select a user type.
6. Enable the options under *Inactivity Periods*. By default the options are disabled. At least one of the status fields *Block after* or *Delete after* must be enabled.

Option	Description
Blocking status	When enabled, configure the *Block after* period. The *Block after* period can be between 14 and 2000 days.
Deletion status	When enabled, configure the *Delete after* period. The *Delete after* period can be between 14 and 2000 days. → Remember If you configure both *Block after* and *Delete after* periods, the *Delete after* period must be longer than the *Block after* period.
Deletion script start date	This status is optional and it appears only after the *Deletion status* is enabled. Configure the date after which the deletion script starts. The automatic configuration is based on the current date plus the days specified in the *Delete after* period. The deletion process starts from the chosen date and is runs nightly at 04:00 UTC.
Creation grace period status	This status is optional and it can be configured only after the *Deletion status* is enabled. When enabled, configure when users who have been created but never logged in will be deleted. The grace period can be between 2 and 30 days. → Remember If the status is disabled, users that are created before the start of the deletion script, but have never logged in, they will be deleted even if the period of their inactivity is less than the delete after period that is configured in the administration console.

7. Save your changes.

Next Steps

To unblock users, follow the procedure in Unblock a User [page 2369]

1.7.11.9 Delete Users

As a tenant administrator, you can delete users in the administration console.

Context

→ Remember

You are not allowed to delete your own user profile.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Select the checkbox next to the user or users that you want to delete.

   > → Tip
   >
   > If you don't see the user or users that you want to delete, you can expand the list or use the search field. For more information, see Search Users [page 2359].
4. Press *Delete*.
5. Confirm the operation.

   > ⚠ Caution
   >
   > If the user you delete is also an administrator, he or she will be removed from the administrator list too. For more information about how to remove and administrator, without deleting it from the user data base, see Edit Administrator Authorizations [page 2309].

1.7.11.10 Deactivate Users

As a tenant administrator, you can deactivate users in the administration console for SAP Cloud Identity Services.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Find the user that you want to deactivate.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
4. Select the user that you want to deactivate.

   This operation opens the *Details* view.
5. **Optional:** Choose the *Details* tab.
   a. Expand the *Personal Information*
   b. Press the *Edit* button at the top of the screen.
   c. Select *Inactive* from the dropdown next to the *Status* field.
6. Save your changes.

   If the operation is successful, the system displays the message `User <user ID> updated`.

Results

When a user with status `Inactive` tries to log on to an application the following message appears: `Sorry, we could not authenticate you. Try again.`

When a user is with a status `Inactive`, all actions in the *Password Details* page under the *Authentication* tab of *User Management* are disabled.

> ⓘ Note
>
> To active a user again, set the *Status* to `Active`.

1.7.11.11 Unblock a User

Unblock a user that has been blocked due to inactivity.

Context

The inactivity period is configurable and can be between 14 days and 2000 days. For more information, see Block or Delete Users Due to Inactivity [page 2366].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Find and select the user that you want to unblock.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].

   This operation opens the *Details* view.
4. Choose *Authentication* > *User Status* > *Unblock*.

1.7.11.12 Multi-Factor Authentication

This section provides information about how to manage the multi-factor authentication user settings in the administration console for SAP Cloud Identity Services.

Deactivate Two-Factor Authentication [page 2370]

You can deactivate the second factor (passcode or security key) if the user has activated it via the profile page.

Deactivate User Devices for TOTP Two-Factor Authentication [page 2371]
This document shows you how to deactivate the mobile devices used by a user to generate passcodes for access to applications requiring time-based one-time (TOTP) as two-factor authentication. You deactivate the user mobile devices from the administration console for SAP Cloud Identity Services.

Unlock User TOTP Passcode [page 2372]
You can unlock a user passcode when the user must log on to the application before the automatic unlock time of 60 minutes has passed.

Remove User Device for Web Two-Factor Authentication [page 2373]
This document shows you how to remove the registered devices used by a user for access to applications requiring web two-factor authentication (FIDO2 standard).

Unlock User SMS Code [page 2374]
You can unlock a user SMS code when the user must log on to the application before the automatic unlock time of 60 minutes has passed.

Allow Users to Protect Accounts with Second Factor for Authentication [page 2376]
Tenant administrator can allow users to decide whether to protect their own accounts with second factor for authentication or not.

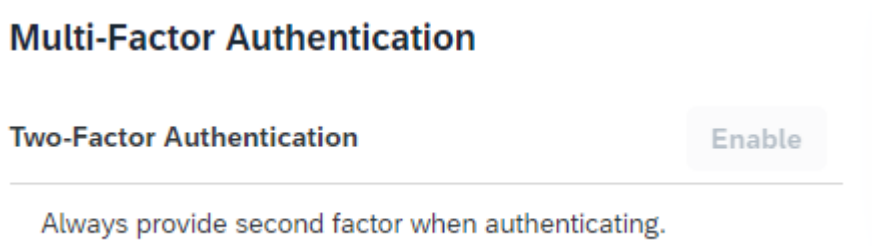
Allow Users To Skip Two-Factor Authentication Setup [page 2378]
You can set the number of days for which the users can postpone the enabling of second factor for authentication.

1.7.11.12.1 Deactivate Two-Factor Authentication

You can deactivate the second factor (passcode or security key) if the user has activated it via the profile page.

Context

When you deactivate the two-factor authentication via the administration console for SAP Cloud Identity Services, the user sees the option disabled on the profile page under the *Multi-Factor Authentication* section:



Once the two factor authentication option is deactivated, the user won't be required to provide a second factor for stronger authentication but the registered devices for access to applications requiring TOTP two-factor or web two-factor authentication (FIDO2 standard) will be preserved in the user's account. Thus, if the two-factor authentication is enabled again, the user will be able to use the already registered devices.

To deactivate the *Two-Factor Authentication* option, proceed as follows:

Procedure

1. Find and select the user whose device you want to remove.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Choose the *Authentication* tab.
3. Choose *Multi-Factor Authentication*.
4. Under *Two-Factor Authentication*, use the slider next to *Status* to deactivate the option.

Task overview: Multi-Factor Authentication [page 2369]

Allow Users To Skip Two-Factor Authentication Setup [page 2378]

1.7.11.12.2 Deactivate User Devices for TOTP Two-Factor Authentication

This document shows you how to deactivate the mobile devices used by a user to generate passcodes for access to applications requiring time-based one-time (TOTP) as two-factor authentication. You deactivate the user mobile devices from the administration console for SAP Cloud Identity Services.

Context

You deactivate all user's mobile devices that generate passcodes if a single device has been lost or stolen. You cannot deactivate a single device.

> **Note**
>
> If you deactivate the mobile devices, the user will no longer be able to log on to applications that require passcodes. To be able to access them again the user has to activate a new mobile device on the user profile page. For more information, see the Related Information.

To deactivate the mobile devices that generate passcodes, proceed as follows:

Procedure

1. Find the user whose device you want to deactivate.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Select the user whose device you want to deactivate.
3. Choose the *Authentication* tab.
4. Choose *Multi-Factor Authentication*.
5. Under *TOTP*, use the slider next to *Status* to deactivate two-factor authentication.

Task overview: Multi-Factor Authentication [page 2369]

Allow Users to Protect Accounts with Second Factor for Authentication [page 2376]
Allow Users To Skip Two-Factor Authentication Setup [page 2378]

1.7.11.12.3 Unlock User TOTP Passcode

You can unlock a user passcode when the user must log on to the application before the automatic unlock time of 60 minutes has passed.

Context

The user locks his or her passcode after submitting five incorrect passcodes when trying to log on to an application that requires time-based one-time (TOTO) two-factor authentication. The passcode is unlocked automatically after 60 minutes.

> **Note**
>
> When the user locks his or her TOTP passcode, he or she will not be able to log on only to applications that require TOTP passcodes. The applications that do not require two-factor authentication will be accessible only with the user password.

To unlock the user TOTP passcode manually, proceed as follows:

Procedure

1. Find the user whose TOTP passcode you want to unlock.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Select the user that you want to unlock.

   > **Note**
   >
   > You can only unlock locked user TOTP passcodes.
3. Choose the *Authentication* tab.
4. Choose *Multi-Factor Authentication*.
5. Press *Unlock* under *Passcode Status*.

   The system displays the message `Account <name of user> unlocked`.

1.7.11.12.4 Remove User Device for Web Two-Factor Authentication

This document shows you how to remove the registered devices used by a user for access to applications requiring web two-factor authentication (FIDO2 standard).

Context

You remove the user's device by deleting it from the administration console for SAP Cloud Identity Services.

> **Note**
>
> When you remove the device, the user will no longer be able to log on to applications that require web authentication. To be able to access them again the user has to activate a new device on the user profile page or when prompted when logging on to an application. For more information, see the Related Information.

To remove the devices registered for web authentication, proceed as follows:

Procedure

1. Find and select the user whose device you want to remove.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Choose the *Authentication* tab.
3. Choose *Multi-Factor Authentication*.
4. Under *Web* delete the device that you want to remove.

Task overview: Multi-Factor Authentication [page 2369]

1.7.11.12.5 Unlock User SMS Code

You can unlock a user SMS code when the user must log on to the application before the automatic unlock time of 60 minutes has passed.

Context

The user locks his or her SMS code after requesting five codes when trying to log on to an application that requires SMS two-factor authentication. The code is unlocked automatically after 60 minutes.

> ⚠ Caution
>
> If the user phone is not verified, the code will not be unlocked after 60 minutes. In this case you should unlock the code via the procedure below.

> ⓘ Note
>
> When the user locks his or her SMS code, he or she will not be able to log on only to applications that require SMS codes. The applications that do not require SMS two-factor authentication will be accessible only with the user password.

To unlock the user SMS code manually, proceed as follows:

Procedure

1. Find the user whose SMS code you want to unlock.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
2. Select the user that you want to unlock.

   > ⓘ Note
   >
   > You can only unlock locked user SMS codes.
3. Choose the *Authentication* tab.
4. Choose the *Authentication* tab.
5. Choose *Multi-Factor Authentication*.
6. Press *Unlock* under *SMS Status*.

   The system displays the message `Account <name of user> unlocked`.

1.7.11.12.6 Allow Users to Protect Accounts with Second Factor for Authentication

Tenant administrator can allow users to decide whether to protect their own accounts with second factor for authentication or not.

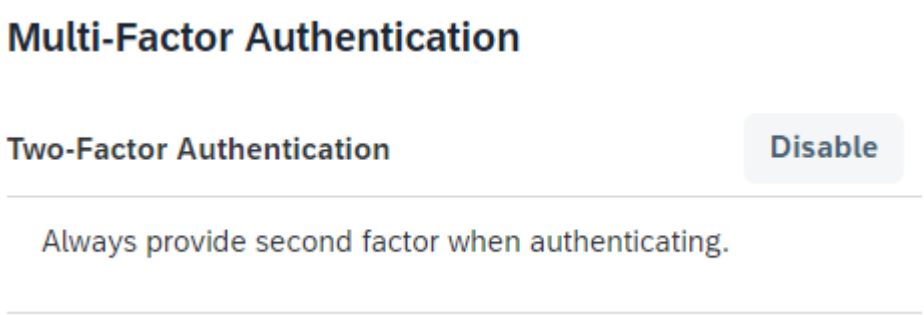
Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

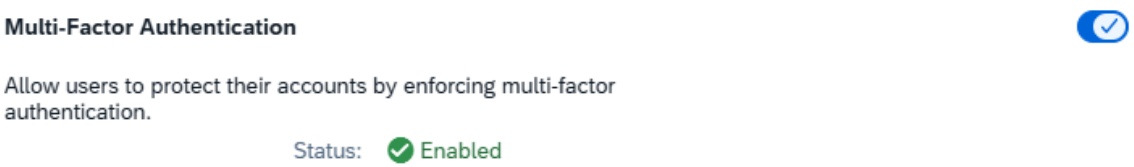
Context

If applications don't require second factor for authentication, or the applications have configured risk-based authentication rules requiring second factor, but the users don't fall into these rules that require second factor for authentication, the users can enhance their security by switching on the *Multi-Factor Authentication* option on the profile page.

> **Note**
>
> The option is switched on by default for all tenants that are created after the February 26, 2026 upgrade of SAP Cloud Identity Services.



This option is visible on the profile page, when it is enabled on the administration console.



When the *Multi-Factor Authentication* option in the administration console is switched on, the users can choose to always provide second factor when authenticating.

If users chose the *Trust this browser* checkbox, the second factor is required only with the first logon. The validity of *Trust this browser* depends on the configuration in the administration console. It can be set between 1 and 14 days. If the additional option for trust this browser is set at *Disabled* the validity of *Trust this browser* is 3 months. But if the administrator sets a validity from 1 to 14 days, the 3-month validity is overridden with the validity set by the tenant administrator.

To enable or disable the *Multi-Factor Authentication* option in the administration console, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Multi-Factor Authentication* list item.
4. Enable or disable the *Multi-Factor Authentication* option.

   If the operation is successful, the system displays the message `Multi-Factor authentication updated`.

Results

Users can choose from the *Multi-Factor Authentication* section on their profile page to protect their accounts with additional forms of authentication.

Task overview: Multi-Factor Authentication [page 2369]

Configure Risk-Based Authentication for an Application [page 2007]
Configure Default Risk-Based Authentication for All Applications in the Tenant [page 2183]

1.7.11.12.7 Allow Users To Skip Two-Factor Authentication Setup

You can set the number of days for which the users can postpone the enabling of second factor for authentication.

Prerequisites

- You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured the application or the tenant to require two-factor authentication. For more information, see Configure Risk-Based Authentication for an Application [page 2007] or Configure Default Risk-Based Authentication for All Applications in the Tenant [page 2183].

Context

The number of days for which users can postpone the enabling of second factor can be set between 1 and 14 days. The configuration is valid for all applications in the tenant. The default setting is 14 days.

> **Note**
>
> The option is switched on by default for all tenants that are created after the February 26, 2026 upgrade of SAP Cloud Identity Services.

If the tenant or application requires two-factor authentication, and the users don't have an enabled two-factor authentication method, or the method that is enabled is not among the ones required by the application, at sign-in users can choose to skip the enabling of two-factor authentication for the period defined by the tenant administrator. The users can sign in without providing a second factor until the grace period expires.

Users can be notified for their choice, if the security alert notification is switched on. They receive a security alert email after they first skip the enabling of two-factor. For more information about how to configure the e-mail alerts, see Send Security Alert Emails [page 2209].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Choose the *Multi-Factor Authentication* list item.
4. Under *Additional Settings for Multi-Factor Authentication*, choose *Edit*.

5. Under *Second Factor Activation Postponement*, choose *Enabled*.
6. Manually configure the number of days for which users can postpone the enabling of second factor.
7. Save your changes.

   If the operation is successful, the system displays the message `Additional Multi-Factor Authentication Settings updated`.

1.7.11.13 Manage User Passwords

This section provides information about how to unlock user passwords, trigger email reset, manage email sending limits, and set initial password.

Unlock User Password [page 2380]
: You can unlock a user password when the user must log on to the application before the automatic unlock time of 60 minutes has passed, or if the *Password Locked Period* in the password policy is set at *unlimited*.

Send Reset Password Email [page 2381]
: You can trigger the sending of an email to the user with reset password information.

Reset Counter for Email Sending [page 2383]
: You can reset the counter for the number of emails that can be sent to the user.

Set Initial Password [page 2384]
: You can set initial password for a user that has already activated his or her account.

1.7.11.13.1 Unlock User Password

You can unlock a user password when the user must log on to the application before the automatic unlock time of 60 minutes has passed, or if the *Password Locked Period* in the password policy is set at *unlimited*.

Context

The user locks the password after submitting five incorrect passwords when trying to log on to the account. The user receives a notification email that the password log on to the account has been disabled for 60 minutes. The user can either choose the link provided in the email to set a new password, or wait for 60 minutes and then log on with his or her current password.

If the *Password Locked Period* in the password policy is set at *unlimited*, the password can be unlocked only by the tenant administrator. When a user locks the password and then tries to reset it, they get the following message : "Your password is locked. Please contact your system administrator to unlock it." In this case the email template set must also be changed. Otherwise, the user will receive an email stating that password logon to the account was disabled for - 1 hour. For more information, see Configuring Email Templates [page 2282].

> → Remember
>
> Identity Authentication can send to the user up to three emails (forgot password, reset password, locked password, email verification) per 24 hours.
>
> If the user must receive more than three emails, the administrator must reset the counter for email sending first. For more information, see Reset Counter for Email Sending [page 2383].

The tenant administrator can unlock the logon to the user account via the administration console.

> ⚠ Restriction
>
> When a user is with a status `Inactive`, unlocking the user password is disabled. For more information, see Deactivate Users [page 2368].

To unlock the user password manually, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Choose the user whose password you want to unlock.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
4. Choose *Password Details* under the *Authentication* tab.
5. Choose *Unlock*.

> → Remember
>
> You can only unlock locked user passwords.

Results

The password is unlocked. The user can now access his or her account after providing the correct credentials.

Task overview: Manage User Passwords [page 2379]

Related Information

Send Reset Password Email [page 2381]
Reset Counter for Email Sending [page 2383]
Set Initial Password [page 2384]
Send Reset Password Email [page 2381]

1.7.11.13.2 Send Reset Password Email

You can trigger the sending of an email to the user with reset password information.

Context

Tenant administrator can trigger the sending of an email to the user with reset password information. When the user follows the link provided in the email, the reset password screen appears and the user is prompted to set a new password.

> ⓘ Note
>
> In this scenario, the email that is sent uses the Forgot Password template set that is defined for the User Prfile application. For more information, see View Email Template Document [page 2288].

Identity Authentication can send to the user up to three emails (forgot password, reset password, email verification) per 24 hours. This counter includes also the emails sent with passcode for TOTP deactivation. If you send three emails within 24 hours, the user will not be able to request a passcode for TOTP deactivation via the profile page during these 24 hours.

If the user must receive more than three emails, the administrator must reset the counter for email sending first. For more information, see Reset Counter for Email Sending [page 2383].

→ Tip

Configure SAML 2.0 Service Provider [page 1941].

⚠ Restriction

When a user is with a status `Inactive`, sending reset password email to that user is disabled. For more information, see Deactivate Users [page 2368].

To send a reset password email, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Choose the user whose password needs to be reset.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].

   → Remember

   The maximum number of emails that can be sent to a user within 24 hours is three. This counter includes also the emails sent with passcode for TOTP deactivation. If you send three emails within 24 hours, the user will not be able to request a passcode for TOTP deactivation via the profile page during these 24 hours.

   If you need to send more emails, first reset the password counter. For more information, see Reset Counter for Email Sending [page 2383].
4. Choose *Password Details* under the *Authentication* tab.
5. Press *Send Email*.

Results

The user receives an email with information how to reset his or her password. After resetting the password, he or she is able to log on to the account.

Task overview: Manage User Passwords [page 2379]

Related Information

1.7.11.13.3 Reset Counter for Email Sending

You can reset the counter for the number of emails that can be sent to the user.

Context

By default, Identity Authentication sends up to three emails per 24 hours. If three emails are sent, but it is necessary to send a new email, the tenant administrator must first reset the counter for email sending.

> ⚠ Restriction
>
> When a user is with a status `Inactive`, resetting the counter for that user is disabled. For more information, see Deactivate Users [page 2368].

To reset the counter for email sending, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Choose the user whose email counter needs to be reset.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
4. Choose *Password Details* under the *Authentication* tab.
5. Press *Reset Counter*.

Results

The counter for the number of emails that can be sent to the user is reset to zero.

Task overview: Manage User Passwords [page 2379]

1.7.11.13.4 Set Initial Password

You can set initial password for a user that has already activated his or her account.

Prerequisites

You are assigned the *Manage Tenant Configuration* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

Tenant administrator can set an initial password for a user that has already activated the account. When the user logs on with the new password, he or she is prompted to change the password with a new one.

> ⚠ Restriction
>
> The initial password can be valid between 1 and 365 days depending on the configuration made by the administrator. The default value is 14 days. The user is prompted to reset the password during the first authentication. After the validity of the initial password expires, the user can't log on to the application and must contact an administrator. For more information for more information about how to configure the initial password validity, see Configure Initial Password and Email Link Validity [page 2168].

> → Tip
>
> Configure SAML 2.0 Service Provider [page 1941].

> ⚠ Restriction
>
> When a user is with a status `Inactive`, setting initial password to that user is disabled. For more information, see Deactivate Users [page 2368].

To set an initial password, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Choose the user who needs an initial password.

   For more information about how to find a user in Identity Authentication, see Search Users [page 2359].
4. Choose *Password Details* under the *Authentication* tab.
5. Press *Set Initial*.

Results

The user logs on to the application with the new password set by the tenant administrator. He or she is prompted to change the password with a new one. After changing the password, the user is able to log on to the application.

1.7.11.14 Restrict User Attributes Values via Exclude Lists

You can restrict the values that can be set on the email, first and last name attributes of the user.

Context

The configured exclude lists for email, first and last name attributes are considered in the user creation and user update via the Identity Authentication SCIM API, Identity Directory SCIM API, the administration console for SAP Cloud Identity Services, and user import.

If the exclude lists are empty, you can create and update a user with any value for email, first and last name attributes.

To create exclude lists for email, first and last name attributes, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Exclude Lists* tile.
3. Choose the tab for the attribute that you want to restrict:
   - First Name
   - Last Name
   - Email
4. Choose *Create* and enter the exclude terms as free text in the field.

   For multiple values, use comma between them.
5. Confirm your changes by choosing *Create*.

1.7.11.15 Restrict User Security Keys for Web Two-Factor Authentication

This document shows you how to restrict the security keys used by users of type employee for access to applications requiring web two-factor authentication (FIDO2 standard).

Context

You restrict the employee user's security key by creating a list of security keys that are allowed for authentication. All other security keys that aren't in the allow list are forbidden for usage by the users.

→ Remember

The allow list is valid only for users of the type employee. The other user types aren't affected by the creation of a security key allow list.

When you include a security key in the list, the users will be able to log on to applications that require web authentication only with the security keys are in the list. To be able to access the applications with other security keys, the employee user has to activate a new one on the user profile page or when prompted when logging on to an application. For more information, see the Related Information.

When the allow list is empty, all security keys are permitted for usage by the user.

When you add security keys in the administration console, you can choose from a predefined list, or you can add custom security keys. The AaGuid of the security keys must be in the format `XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX`.

✤ Example

Michael Adams is an administrator at retail company A. He would like to restrict the access to the company's internal portal page only to employees using security keys controlled by the company.

✤ Example

In the administration console, Michael creates the following rule:

Default Authentication Rule

Action	IP Range	Group	Authentication Method	User Type
Web Two-Factor Authentication	Any	Any	Any	Employee

Default Authentication Rule

Default Action: `Deny`

Michael Adams restricts also the Web Two-Factor Authentication to only the company's custom security key by providing `ab1c23de-4f56-7890-1g23-4h56a7869012` for the AaGuid.

Dona Moore is working at Company A and as such her user type is `Employee`. As an employee she has a company's security key. She has registered it at her profile page. So when she logs on to the portal page she provides her user name and password, and then she proves her identity with the company's security key.

Julie Armstrong is also an employee at company A, but she does't have a custom security key like Dona. When she is prompted to prove her identity, she tries another security key, but the authentication fails.

Richard Wilson is a supplier to Company A. His user type is `Partner`. When he tries to log on to the portal page with his user name and password, his authentication fails.

To create an allow list of the security keys, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.
3. Under *Authentication*, choose *Multi-Factor Authentication* > *WebAuthn Security Keys*.
4. Choose the *Add* button.
5. Provide the required information in the input fields.
6. Confirm the information with the *Add* button.
7. Repeat the procedure for all security keys that you want to put into the allow list.

1.7.11.16 Manage Custom Schemas via Administration Console

You can view and define your custom schema via the administration console for SAP Cloud Identity Services.

Context

The administration console shows information about all existing schemas, predefined, and custom, in the tenant.

If you need your own custom attributes for users you can define your own custom schema, and once the schema is defined, the custom attributes that it defines can be used.

To be used, the custom attributes must be assigned to the user first. For more information, see Configuring Attributes Based on Flexible Expressions [page 1979].

> **Note**
>
> When the attributes are assigned to a user, they can be sent to the application. For more information, see Configuring User Attributes from the Identity Directory [page 1973].

You can define a schema either by importing a JSON file, which must comply with the SCIM standard, or by creating it manually via the administration console.

You can check the available schemas in the tenant, and use one of the predefined schemas. You can also import, or manually create your custom schema. The maximum number of all custom schemas, imported and manually created, per tenant is 20. Each schema can have up to 20 attributes. Each multivalued attribute of type `complex` can have up to 20 subattributes.

You can also download a schema template or any of the already existing schemas. You can use the template to define your own schema extensions.

> ⚠ Caution
>
> The schemas in the administration console are read-only. To edit a custom schema, you must delete it and import a new one with the necessary changes. If you delete a schema this will also delete the attributes and subattributes in this schema and their values, and remove all already assigned attributes to users from this schema.
>
> You can delete only custom schemas.

> ⓘ Note
>
> For more information about the SCIM Core Schema, see 7. Schema Definition .

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Schemas* tile.

   This operation opens the *Schemas* page with all the schemas in the tenant, predefined, and custom.
3. Choose *Actions* button, then choose one of the options:
   - *Template* - Download a schema template. You can use the template to define your own schema extensions.

     > ⓘ Note
     >
     > To download an existing scema, select the schema in the list on the left and choose the *Export* button in the right top corner.

   - *Import* - Upload the JSON file with your SCIM-compliant schema.
     The following singular and multivalued attributes are defined:

     Singular Attributes

Attributes	Notes
`id`	Required Example: `"id": "urn:sap:cloud:scim:schemas:extension:custom:2.0:MyCustomSchema",`

Attributes	Notes
`name`	Optional **Note** If present, it's validated against the `id`, and must match it. Example: `"name": "MyCustomSchema",`
`description`	Optional Example: `"description": "Custom schema description",`

Multi-Valued Attributes

Attribute	Subattributes	Notes
`attributes`		Required. A set of schema attribute objects which contains the attribute qualifications.
	`name`	Required
	`type`	Required Values: "string", "boolean", "decimal", "integer", "dateTime", "reference", and "complex". **→ Remember** "type=complex" fits only to attribute. If an attribute is marked as "type=complex" and "multiValued = true" this attribute must have at least one subattribute.
	`subAttributes`	Optional. **→ Remember** Required, when main attribute is of type "complex". "subAttributes" has the same schema qualification settings as "attributes".

Attribute	Subattributes	Notes
	`multiValued`	Required Boolean → Remember When attribute is marked as "multiValued=true", the type can only be "complex". If an attribute is marked as "type=complex" and "multiValued = true" this attribute must have at least one subattribute.
	`description`	Optional
	`required`	Required Boolean
	`canonicalValues`	Optional A set of supported values for the attribute.
	`caseExact`	Required Boolean
	`mutability`	Required Values: "readOnly", "readWrite", "immutable", and "writeOnly".
	`returned`	Required Valid key words: "always", "default", "never", and "request".
	`uniqueness`	Required Valid key words: "none", "server", and "global".

Attribute	Subattributes	Notes
	`referenceTypes`	Optional Valid values: • A SCIM resource type (for example "User" or "Group") • "external" - indicating that the resource is an external resource • "uri" - indicating that the reference is to a service endpoint or an identifier

- *Create* - Manually create a custom schema. Fill in the required information and add the attributes. The following singular and multivalued attributes are defined:

Attribute Name	Provide a name for the attribute. Each attribute must be unique within the schema.
Parent Attribute	Choose a parent for the attribute from the existing attributes of type complex. **Note** A parent attribute is a previously configured "multiValued" attribute of type "complex".
Type	Select a value from the drop-down: • "string" (default value) • "boolean" • "decimal" • "integer" • "dateTime" • "reference" • "complex" **→ Remember** If an attribute is marked as "Type=complex" and "Multi-Valued = true" this attribute must have at least one subattribute.
Mutable	Select a value from the drop-down: • "readOnly" (default value) • "readWrite" • "immutable" • "writeOnly"

Returned	Select a value from the drop-down: • "always" (default value) • "default" • "never" • "request"
Unique	Select a value from the drop-down: • "none" (default value) • "server" • "global"
Description	Optional.
Canonical	Optional.
Required	Boolean. When checkbox is selected, the value is "true". Default value is "false".
Case Exact	Boolean. When checkbox is selected, the value is "true". Default value is "false".
Multi-Valued	Boolean. When checkbox is selected, the value is "true". Default value is "false".

Results

The newly created schemas appear in the list on the left. The schemas are listed in alphabetical order.

1.7.12 Managing Groups

Tenant administrators can create groups, and assign and unassign these groups to users via the administration console for SAP Cloud Identity Services.

A group is a collection of users. Groups serve to create sets of users who have something in common. For example, users who work in the same department or users who have similar tasks in a company.

Import Groups via CSV File [page 2395]

As a tenant administrator, you can create new groups or update existing ones with the assigned users, via a CSV file upload.

Create a Group [page 2398]
: As a tenant administrator you can create groups in the tenant to organize users based on common characteristics, authorization, or application via the administration console for SAP Cloud Identity Services.

List and Edit Groups [page 2400]
: As a tenant administrator, you can list and edit information about the groups in a tenant in the administration console for SAP Cloud Identity Services.

Enable or Disable Central Store-Based Provisioning [page 2401]
: You can enable or disable the *Central Store-Based Provisioning* option in the administration console for SAP Cloud Identity Services.

Manage Application-Specific Groups by Identity Provisioning [page 2402]
: By running provisioning jobs, you can create application-specific groups in the Identity Directory of your SAP Cloud Identity Services tenant or Identity Authentication (SCIM API version 2) target system and provision them afterward to target systems of your choice.

List and Search Users in Groups [page 2405]
: As a tenant administrator, you can list and view information about the users in a group in a tenant in the administration console for SAP Cloud Identity Services.

Add Users to a Group [page 2406]
: As a tenant administrator, you can add one or more users created for a specific tenant to a group via the administration console for SAP Cloud Identity Services.

Remove Users from a Group [page 2408]
: As a tenant administrator, you can remove one, more than one, or all users added to a group via the administration console for SAP Cloud Identity Services.

Assign Groups to a User [page 2409]
: As a tenant administrator, you can assign one or more groups created for a specific tenant to a user via the administration console for SAP Cloud Identity Services.

Unassign Groups from a User [page 2410]
: As a tenant administrator, you can unassign one or more groups that are assigned to a user via the administration console for SAP Cloud Identity Services.

Delete Groups [page 2411]
: As a tenant administrator, you can delete one or more groups in administration console for SAP Cloud Identity Services.

1.7.12.1 Import Groups via CSV File

As a tenant administrator, you can create new groups or update existing ones with the assigned users, via a CSV file upload.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

With the CSV file, you can import up to 25000 groups to create new groups or to update existing ones with their user assignments.

If the group does not exist in the tenant, and you provide that group in the CSV file, the group will be created. The CSV file must contain the `groups` column. The value of the `groups` column is recorded as `name` and `displayName` in the newly created group. You cant set `description`, or separately provide `name` or `displayName` in the CSV file. No user assignment is required when creating a new group.

You can only add users to the groups via the import groups option, you don't remove users from the groups.

> ⚠ Caution
>
> The supported number of users in a group is 344,000 members. If you exceed this number, the operations with the group might not work properly.

→ Remember

When you create new groups with user assignments, or update existing ones with their user assignments, make sure that the CSV file contains unique users with unique identifiers.

The CSV file must contain the `groups` column and a column with at least one of the following identifiers:

- *Global User ID*
- *Email* - `emails[0].value`

  #### ⓘ Note

  - If the `emails[0].value` is not unique, and there are more than one users with one and the same email, all the users with that email in the CSV will be assigned to the group.
  - If the `emails[0].value` is not unique, and there are more than one users with one and the same email, you can distinguish the users by the `userName` or `userUuid` attribute. If you use the `userUuid` attribute, make sure that the user that you want to assign the group has it.
- *User Name*

If the file contains more than one identifier then the priority will be:

1. Global User ID
2. Email
3. User Name

If the file contains email and user name, a combination of both will be used as identifier. Thus the user will be matched with the email and user name at the same time.

If the CSV file contains one and the same email identifier, then the group will be assigned to all users that has this email.

ⓘ Note

The user import doesn't assign any special rights or roles to the users for the specific application.

The CSV file can contain only columns with no spaces between the values.

If you enter the data in the CSV file as text, you must separate the entries with commas. Beware not to put any spaces before or after the commas. If you enter more than one value in a single entry, separate the values within the entry with semicolons.

✤ Example

{·} Sample Code

```
groups,urn:ietf:params:scim:schemas:extension:sap:2.0:User:userUuid,emails[
0].value
HR,1ab2e307-1c7c-4c37-9bcf-ed0123456789,dona.moore@example.com
Management,1ab2e307-1c7c-4c37-9bcf-ed0123456700,management@example.com
IT,1ab2e307-1c7c-4c37-9bcf-ed0123456712,management@example.com
```

To import groups via CSV file into Identity Authentication, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.
3. Press the *Import* button.
4. Choose the *Browse...* button and specify the location of the CSV file.

   > ⓘ Note
   >
   > Use a UTF-8 encoded file with up to 25000 groups and an extension `.csv`. If your file contains more than 25000 groups, you have to import the groups information in iterations within the group number limit.

   > → Tip
   >
   > If you import groups from one tenant to another, you can first export the users from the first tenant via the export users option, and then use the exported CSV file for the import to the other tenant or tenants. For more information, see Export Existing Users of a Tenant of Identity Authentication [page 2356].

5. Choose the *Save* button.

   If the operation is successful, the system displays a message with the number of imported and updated groups.

Delete Groups [page 2411]

1.7.12.2 Create a Group

As a tenant administrator you can create groups in the tenant to organize users based on common characteristics, authorization, or application via the administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

You can choose whether to create just a user group or a user group that is application-specific. For more information about the different groups in the Identity Directory of Cloud Identity Services, see Groups [page 514].

To create a new user group, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Press the *+ Create* button at the top of the page.
4. In the *General* screen, fill in the required information, and choose *Next Step*.

   You have the following options:

Field	Notes
Name	Required. The name of the group. → Tip To ensure successful group provisioning from SAP Cloud Identity Access Governance, create the groups in Identity Authentication with length of their names within 40 characters.
Display Name	Required. The display name of the group.
Description	Optional. Additional information for the group.

5. **Optional:** In the *Application (Optional)* screen, fill in the information if you want to create an application-specific group.

a. Select an application from the list to create an application-specific group.
b. Choose a group type:
   - *userGroup* - A group of users who have something in common.
   - *authorization* - A group related to authorization of users, groups or applications.
   - *deepLinkActivationPermission* - A group of applications that support deep linking.

   For more information about the group, see Groups [page 514].

   > → Remember
   >
   > At the creation of the group, the *Supported Operations* field is set to `readWrite` and is read-only. For more information about supported operations, refer to the *Application-Specific Groups Supported Operations* table in Groups [page 514].

6. Choose *Next Step* > *Finish*.

Results

If the operation is successful, the system displays the message: `Group "<name of the group>" updated`. Identity Authentication creates the new group and assigns the *Group ID* to it. *Group ID* is in the universally unique identifier (UUID) format. If the group is application-specific the *Application Name* is also assigned to the group.

Task overview: Managing Groups [page 2393]

Groups [page 514]

1.7.12.3 List and Edit Groups

As a tenant administrator, you can list and edit information about the groups in a tenant in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have created groups in your tenant. For more details on how to create groups, see Create a Group [page 2398].

Context

The groups are sorted in alphabetical order of the display name.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Choose a group from the list on the left to view its details.

   > → Tip
   >
   > Type a `Group ID`, `Display Name`, or `Name` of a group in the search field to filter the list items. Choose *Show Filter Bars* for advanced search. You must be assigned to a policy that allows reading applications to view the information for *Application Name*.
4. **Optional:** Press the *Edit* button at the top-right corner of the screen.
   a. Edit the *Display name* or *Description* fields, or both.
   b. Save your changes.

1.7.12.4 Enable or Disable Central Store-Based Provisioning

You can enable or disable the *Central Store-Based Provisioning* option in the administration console for SAP Cloud Identity Services.

Prerequisites

- You have an application specific group in your tenant. For more details on how to create groups, see Create a Group [page 2398].
- You have configured the **Central Store-Based Provisioning** in the administration console for SAP Cloud Identity Services. For more information, see Central Store-Based Provisioning [page 579].

Context

When you enable the *Central Store-Based Provisioning* for a specific application, whenever you update an application-specific group associated with this application, a provisioning of the updates is triggered from the Local Identity Directory to a target system of your choice. There is no need to run manual or scheduled jobs in the Identity Provisioning.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Under the *Provisioning* tab, enable or disable the *Central Store-Based Provisioning* option.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

1.7.12.5 Manage Application-Specific Groups by Identity Provisioning

By running provisioning jobs, you can create application-specific groups in the Identity Directory of your SAP Cloud Identity Services tenant or Identity Authentication (SCIM API version 2) target system and provision them afterward to target systems of your choice.

Prerequisites

You have an existing application in your SAP Cloud Identity Services tenant. For more information, see Create a New Application [page 1922].

Context

The application-specific groups are a special kind of groups which can be created in the Identity Directory of SAP Cloud Identity Services or Identity Authentication (SCIM API version 2) target system by running provisioning jobs, or via the administration console for SAP Cloud Identity Services. For more information, see Create a Group [page 2398].

Operating with application-specific groups by the Identity Provisioning service requires having a source system with set property `ips.application.id`. By running provisioning jobs from such source system you can create, update, and delete application-specific groups in the Identity Directory of your SAP Cloud Identity Services tenant or Identity Authentication (SCIM API version 2) target system, depending on the values of their attributes.

Each application-specific group contains information about the application to which it is associated through the `application ID`. That is how you can distinguish which group comes from which application (or provisioning system in the context of Identity Provisioning) in the Identity Directory or Identity Authentication (SCIM API version 2) target system.

Another specific attribute for these groups is `supportedOperations`. The purpose of this attribute is to specify what are the supported operations by the Identity Provisioning for each application-specific group. For more information, see Groups [page 514].

> **Note**
>
> To find out which connectors support application-specific groups, check the list of systems under *System Types* for the `ips.application.id` property in List of Properties [page 80].

The result from each operation with an application-specific group executed by the Identity Provisioning, depending on the value of its attribute `supportedOperations`, is described below.

Create Application-Specific Groups

By running provisioning jobs from your source system, associated to an application, you can create application-specific groups in the Identity Directory of your SAP Cloud Identity Services tenant or Identity Authentication (SCIM API version 2) target system.

When you configure Local Identity Directory or Identity Authentication (SCIM API version 2) as source system and you try to create a group that already exists in the target system with matching attributes and `supportedOperations` attribute value `userOnlyMembership` or `membership`, its group members are updated. If you try to provision a group with value `readOnly` for the attribute `supportedOperations`, it is displayed as *Skipped* in the job log statistics for the source system. In case the group has value `readWrite` for the attribute `supportedOperations`, it is created in the target system.

Update Application-Specific Groups

If you update a user group assignment or a group itself in the application to which is associated your source system and you run a read or resync job, the Identity Provisioning tries to search and resolve this group in the

Identity Directory of your SAP Cloud Identity Services tenant or the Identity Authentication (SCIM API version 2) target system.

In case such application-specific group is found, depending on the value of the attribute `supportedOperations` this will result in:

- `readOnly` - The group is displayed as *Skipped* in the job log statistics for the source system.
- `readWrite` - The attributes of the group and its members are updated.
- `userOnlyMembership` - The group members that are users are updated.
- `membership` - The group members, both users and groups, are updated.

If such group is not found, the job fails with an exception.

Delete Application-Specific Groups

The deletion of application-specific groups from the local directory after they have been deleted from your source system requires setting the property `ips.delete.existedbefore.entities` = *true* in the target system. The setting of the property must be done **before** the job to delete those groups from the target system is executed. For more information, see List of Properties [page 80].

In case you have set the `ips.delete.existedbefore.entities` property before running the provisioning job, depending on the value of the attribute `supportedOperations`, expect the following results:

- `readOnly` - The group is displayed as *Skipped* in the job log statistics.
- `readWrite` - The group is deleted.
- `userOnlyMembership` - The group members that are users are deleted. The group is displayed as *Deleted* in the job log statistics.
- `membership` - The group members, both users and groups, are deleted. The group is displayed as *Deleted* in the job log statistics.

If the property `ips.delete.existedbefore.entities` is missing or set to *false*, the Identity Provisioning will not attempt to delete the group and no record will be displayed in the job log statistics.

Unassign Groups from a User [page 2410]
Delete Groups [page 2411]

1.7.12.6 List and Search Users in Groups

As a tenant administrator, you can list and view information about the users in a group in a tenant in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have created at least one user group in the tenant. For more details about how to create groups, see Related Information.
- You have assigned at least one user to the selected user group. For more details about how to assign groups to a user, see Related Information.

Context

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Type a `Group ID`, `Display Name`, or `Name` of a group in the search field in order to filter the list items.

   > → Tip
   >
   > Choose *Show Filter Bars* for advanced search. You must be assigned to a policy that allows reading applications to view the information for *Application Name*.
4. Choose a group from the list.

   This will open the groups details (*Group ID*, *Name*, *Display Name*, *Description*, *Type*, and *Application Name*) on the right. The users that are part of the group are listed below the user group details.
5. To search for a specific user, type the *SCIM ID*, *Email*, *Login Name* of the user in the search field and press the *Enter* key.

1.7.12.7 Add Users to a Group

As a tenant administrator, you can add one or more users created for a specific tenant to a group via the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have groups created in your tenant.

Context

> ⚠ Caution
>
> The supported number of users in a group is 344,000 members. If you exceed this number, the operations with the group might not work properly.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Choose a group from the list on the left.

   This will show the group details and the users that are added to that group.
4. Press the *Add* button.

   > **Restriction**
   >
   > The *Add* button is hidden for application-specific groups with `readOnly` supported operations.
5. Add users to the group. You have the following options:
   - Select users from the list.
   - Search for the users.
     - *starts with* - (default/recommended operator) returns only users that start with the entered value.
     - *contains* - returns all the users that contain the entered value. Using the *contains* operator may result in longer processing time.

   > **Note**
   >
   > You can filter your search by *First Name*, *Last Name*, *Scim ID*, *Email*, or *Login Name*.
6. Save your changes.

Next Steps

Configure the attributes that are sent to the application in the assertion. For more information, see Configuring User Attributes from the Identity Directory [page 1973]

Create a Group [page 2398]

1.7.12.8 Remove Users from a Group

As a tenant administrator, you can remove one, more than one, or all users added to a group via the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

> ⚠ Restriction
>
> The removal of users is not possible for application-specific groups with `readOnly` supported operations.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Choose a group from the list on the left.

   This will show the group details and the users that are added to that group.
4. Select the users that you want to remove from the group.

   The selected users are highlighted.
5. Press the *Remove* button and confirm the operation.

Unassign Groups from a User [page 2410]
Delete Groups [page 2411]

1.7.12.9 Assign Groups to a User

As a tenant administrator, you can assign one or more groups created for a specific tenant to a user via the administration console for SAP Cloud Identity Services.

Prerequisites

- You have created user groups in your tenant. For more details how to create user groups, see Related Information.
- You are assigned the *Manage Users* and *Manage Groups* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

> ⚠ Caution
>
> The supported number of users in a group is 344,000 members. If you exceed this number, the operations with the group might not work properly.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.

3. Choose the user that you want to assign to a group or groups.
4. Choose the *Groups* tab.
5. Press the *Assign* button at the top of the page.
6. In the dialog box, select the group or groups that you want to assign to the user.
7. Press *Assign*.

Unassign Groups from a User [page 2410]
Delete Groups [page 2411]

1.7.12.10 Unassign Groups from a User

As a tenant administrator, you can unassign one or more groups that are assigned to a user via the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have created groups in your tenant. For more details how to create groups, see Related Information.
- You have assigned groups to the user. For more details how to assign a group or groups to a user, see Related Information.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. Choose the user whose group assignments you want to edit.
4. Choose *Groups* tab.
5. Select the group or groups that you want to unassign.
6. Press the *Unassign Groups* button at the bottom of the page.
7. Confirm your changes.

Task overview: Managing Groups [page 2393]

Create a Group [page 2398]
Assign Groups to a User [page 2409]

1.7.12.11 Delete Groups

As a tenant administrator, you can delete one or more groups in administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Groups* and *Manage Users* roles. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

> ⚠ Restriction
>
> This document does not apply to:
>
> - groups of type *Authorization* and groups associated with an authorization policy. These groups are related to the authorization policies, and when you delete a policy, the respective group is also removed. For more information, see Delete an Authorization Policy [page 2250].
> - application-specific groups with supported operations: `readOnly`, `userOnlyMembership` and `membership`.

The delete groups operation removes groups and unassigns all users from them.

Follow the procedure below for each group that you want to delete:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Groups* tile.

   This operation opens a list of the groups in the tenant.
3. Select the user group that you want to delete.
4. Press the *Delete* button in the right-hand panel.
5. Confirm the operation in the pop-up dialog.

   If the operation is successful, the system displays the message `Group <group name> deleted.`.

1.7.13 Configuring Provisioning Systems

Configure provisioning systems for synchronizing users and groups between business applications.

Administrators create source, target, and proxy systems, configure properties and transformations when necessary. They manage certificates, update connector versions, schedule and run jobs. Other administrator tasks include enabling or disabling systems as well as exporting and importing them.

For more information about the provisioning systems (connectors) available for use as source, target, and proxy systems, refer to Source Systems [page 585], Target Systems [page 936] and Proxy Systems [page 1343], respectively.

> **Note**
>
> This documentation refers to Identity Provisioning in the SAP Cloud Identity Services infrastructure. To access the service documentation in the Neo environment, go to Identity Provisioning Service in the Neo Environment.

Add New Systems [page 2415]
: You can add source, target, and proxy systems for your provisioning scenarios.

Search and Edit Systems [page 2418]
: You can search and edit source, target, and proxy systems in the Identity Provisioning user interface.

Enable and Disable Systems [page 2419]
: You can enable and disable source and target systems in Identity Provisioning.

Export and Import Systems [page 2421]
: You can export and import source, target and proxy systems in Identity Provisioning.

Delete Systems [page 2423]
: You can delete a source, target, or proxy system from Identity Provisioning.

Update Connector Version [page 2424]
: Update a connector version to allow your provisioning system to use a new API.

Manage Properties [page 2438]
: You can add, delete and modify properties for a system in Identity Provisioning.

Manage Transformations [page 2439]
: You can manage transformations with graphical and JSON text editor. Regardless of which one you choose, the following initial steps are the same.

Manage Certificates [page 2450]
: Identity Provisioning supports certificate-based authentication for secure communication with the provisioning systems (connectors) provided by the service.

Configure Form-Based OAuth Authentication [page 2457]
: Configure Identity Provisioning to use form-based OAuth 2.0 authentication to call SAP Ariba Applications APIs.

Manage Full and Delta Read [page 2459]
: When you set up your systems and start a scheduled provisioning task, the standard behavior of the process reads all the entities from the source system. This mode prevents data loss and always keeps your target system synchronized with the source. However, it may take a long time for every job to be executed.

Manage Deleted Entities [page 2463]

Manage deletion of entities (users or groups) in the target system after they have been deleted from the source system.

Connect to On-Premise Systems [page 2468]
: Set up the connection to on-premise systems when your Identity Provisioning bundle or standalone tenant is running on the infrastructure of SAP Cloud Identity Services.

Start and Stop Provisioning Jobs [page 2472]
: You can start and stop a provisioning job from the Identity Provisioning user interface (UI) or from an API client by using the Identity Provisioning tenant admin API.

Handle Rate Limits [page 2481]
: Identity Provisioning APIs implement rate limits to control the number of incoming requests for a given time.

Handle Failed Operations [page 2482]
: In certain cases, you can set a retry for a failed operation due to an occurred exception.

Reset Identity Provisioning Settings [page 2484]
: Resetting your provisioning settings will delete all provisioning systems configured for your tenant, along with the related job execution logs.

Reset Identity Provisioning System [page 2485]
: Resetting an Identity Provisioning system (source or target) deletes all Identity Provisioning operational data.

1.7.13.1 Add New Systems

You can add source, target, and proxy systems for your provisioning scenarios.

To provision entities (users, groups, roles) from one system to another across your enterprise, you first need to add and configure these systems as source and target connectors in Identity Provisioning.

> **⚠ Restriction**
>
> The maximum number of systems you are allowed to add is:
>
> - **20** sources systems
> - **50** target systems
>
> This restriction is valid for *Customer Managed* systems only. If your business requires using more systems, create an incident for component *BC-IAM-IPS* to request them. Describe your scenarios and provide a reason why you need the additional systems.

When you add a system, it is created with its default properties and transformations. If the system has different versions (based on the APIs it provides), you can specify which one you want to use, so that the system is created with the version specific properties and transformations.

Versioning is supported for Identity Authentication, SAP SuccessFactors, SAP Concur, SAP Analytics Cloud and SAP Sales Cloud and SAP Service Cloud. It is controlled by the `<system prefix>.api.version` property.

To add a system, proceed as follows:

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Choose the *Add* button at the top left corner of your screen.
3. On the *Details* tab, provide the following information:

Field	Description
Type	Select the system type that you want to configure.
System Name	Add a name for your system. Make sure it does not duplicate another system's name in the UI. **ⓘ Note** System names can have a length of up to 100 characters. Only the following characters are allowed: (a-z), (A-Z), (0-9), (-), (_), (.) and spaces.

Field	Description
Destination Name	(Optional) Select a destination. If you have previously created a connectivity destination in SAP BTP cockpit on subaccount level, you can access it from the Identity Provisioning UI. **→ Remember** • When you select a connectivity destination, it must be compliant to the relevant system type. • The destination should specify all the connection settings required for your identity provisioning scenario. • For *SAP Application Server ABAP* systems, creating a destination is **mandatory**. If you skip the *Destination Name* field, you can enter the connection and configuration properties, needed for your scenario, on the *Properties* tab. **ⓘ Note** If you use both a connectivity destination and the *Properties* tab, and one and the same property exists in both places, the value set in the *Properties* tab will be considered with higher priority. If you leave both the *Destination Name* field and the *Properties* tab empty and then run a job, no identity provisioning will be performed.
Description	(Optional) Enter a description. It will help you easily distinguish your systems in the list later on.
Source Systems	This field is displayed only for target systems. Select a source system whose identities you want to read and provision to the target one. You can select multiple source systems. **→ Tip** If you had previously added one or more source systems but some of them were later deleted in your Identity Provisioning UI, an error message will appear. To correct this inconsistency, edit the target system configuration (select active source systems), and save the changes.

4. Decide on the version of the system you want to add.

- Choose *Save*, if the system you add has no version, or it has two or more versions and you want the default one. The new system appears in the left-side panel. The default transformations and properties are displayed under the respective tabs.
- Do not choose *Save*, if the system you add has two or more versions and you want to specify a particular one. In this case, proceed as follows:
  1. From the *Details* tab (without saving your configurations), move to the *Properties* tab and select it.
  2. Add the API version property for your system and a value. For example, if you add SAP SuccessFactors on the *Details* tab, add `sf.api.version` and the desired version **2**.
  3. Now, choose *Save*.

  This creates an SAP SuccessFactors system with specific properties and transformation for version 2, which is based on SAP SuccessFactors Workforce SCIM API. Providing value 1, would result in creating a system with specific properties and transformation for version 1, which is based on SAP SuccessFactors HCM Suite OData API.

  > **Note**
  >
  > Once you save your configuration, switching between versions is possible but requires manual work, mostly adding the version specific properties and transformations. For more information, see Update Connector Version [page 2424].

5. To add connection and configuration properties, choose *Properties* > *Edit*. See List of Properties [page 80]
6. To modify your default system transformation (if needed), choose *Transformations* > *Edit*.
7. Save your changes.

At the end of the Identity Provisioning URL, a dash-separated string appears. This is the automatically generated unique ID of the newly created system.

1.7.13.2 Search and Edit Systems

You can search and edit source, target, and proxy systems in the Identity Provisioning user interface.

Prerequisites

Searching and paging of provisioning systems is supported for tenants running on SAP Cloud Identity infrastructure.

Context

Paging is enabled by default. The number of systems loaded per page is 20. They are sorted by type (*Customer Managed* and *SAP Initiated*) and state (*Enabled* and *Disabled*) in the following order:

1. Customer Managed, enabled systems are displayed alphabetically
2. Customer Managed, disabled systems are displayed alphabetically
3. SAP Initiated, enabled systems are displayed alphabetically
4. SAP Initiated, disabled systems are displayed alphabetically

> **Note**
>
> If you can't find the system you are searching for, choose *More* to expand the list of systems as many times as needed until it is displayed.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. From the list on the left, either directly select a system, or search for it and select it.
3. Select a tab and edit the configurations.
   - *Details*
   - *Transformations*

- *Properties*
- *Outbound Certificates*

4. Choose the *Edit* button and make your changes.
5. Save your changes.

1.7.13.3 Enable and Disable Systems

You can enable and disable source and target systems in Identity Provisioning.

Context

To use a system for provisioning purposes, its status has to be **Enabled**. When you add a new system, it is enabled by default. If one of your added systems is configured and you currently do not need it, but would like to use it later, you can disable it.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. From the list on the left, select a system.
3. At the top right corner of your screen, choose one of the following options:
   - If the system is currently disabled, choose the *Enable* button and confirm the action.
   - If the system is currently enabled, choose the *Disable* button and confirm the action.
4. Save your changes.

1.7.13.4 Export and Import Systems

You can export and import source, target and proxy systems in Identity Provisioning.

Context

If you have added and configured a system, you can export it for further use. The export-import function comes in handy in the following use cases:

- You need to back up your system before updating to a new connector version. See: Update Connector Version [page 2424]
- You need another system of the same type but with slightly different setup, and you don't want to manually enter all data and configuration properties all over again.
- You need to reuse an existing system in the Identity Provisioning UI but for another subaccount.
- You have reached the maximum number of systems you are allowed to add. You need to add one more system, which means you must delete some of the previous ones. However, you don't want to lose their configurations, thus you export these systems.

Handle Rate Limits [page 2481]
Handle Failed Operations [page 2482]
Reset Identity Provisioning Settings [page 2484]
Reset Identity Provisioning System [page 2485]

Procedure

Export a System

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. From the list on the left, select the system you want to export.
3. Choose the *Export* button.
4. The exported system configuration depends on your scenario. If your system is a *source* or a *target* one, it will be exported as a JSON file. If it's a *proxy* one, you have two options:
   - Select *JSON format* – the system configuration will be exported as a *.json* file, which you can later import back in the Identity Provisioning UI.
   - Select *CSV format* – the system configuration will be exported as a *.csv* file, which you can later import in the SAP Identity Management UI as a SCIM repository.
5. Save the file on your local file system.

Import a System

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Choose the *Add* button.
3. In section *Define from File*, choose the *Browse* button.
4. Browse and select the file with system configuration you need on your local file system. You can import files with extension **.json** as well as files with no extension.
5. The system configuration is displayed in the *Details* editor. You can also see the imported transformations and properties of this system in the respective UI tabs.
6. Change the *System Name*, otherwise an error message will appear warning you that a system with this name already exists.
7. The *Properties* tab will prompt you to enter the credentials (like passwords or client secrets). When you export a system, credentials are skipped (not displayed as plain text in the *.json* file). Therefore, when you import it, you have to manually enter the passwords/secrets.
8. Save your changes.
   The imported system appears in the left-side panel. Its ID is different than the one of the "original" system (you can see it in the URL).

> ⚠ Caution
>
> You cannot export a target system and import it back as a source, nor the other way around.

1.7.13.5 Delete Systems

You can delete a source, target, or proxy system from Identity Provisioning.

Context

> **Note**
>
> Before you delete a system, make sure you don't need it anymore. If you think you might need it in future, export it first as a JSON or a CSV file. To learn how, see: Export and Import Systems [page 2421]

To delete a system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. From the list on the left, select a system.
3. At the top right corner of your screen, choose the *Delete* button and confirm the action.
4. Save your changes.

Results

The system disappears from the panel.

1.7.13.6 Update Connector Version

Update a connector version to allow your provisioning system to use a new API.

When an SAP cloud solution or service provides a new API for integrating with Identity Provisioning, you can update your respective connector (provisioning system) to use this API by configuring a version property and replacing its transformations.

For example, SAP Sales Cloud and SAP Service Cloud (formerly known as SAP Cloud for Customer) initially provided two SOAP-based APIs for integrating with Identity Provisioning and later introduced a SCIM-based API. Likewise, Identity Authentication service initially provided a SCIM-based API and later introduced an Identity Directory SCIM API.

Version property set to **`1`** means that your connector is using the initial API. You can continue using it as-is or update your connector to a new version.

> **Note**
>
> Before updating your connector to a new version, it is always a good practice to export the system for backup purposes. See: Export and Import Systems [page 2421]

We recommend proceeding with the update of the connector version after executing successfully a provisioning job in **full read** mode for the existing version of the provisioning system.

To update your connector to use a new API, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. From the list on the left, select a system.
3. On the *Properties* tab, configure the following:
    1. **Version Property** - Add or update the **`<system_prefix>.api.version`** property and set its value accordingly.

Connector	Property	Value
Identity Authentication	`ias.api.version`	• **1** - Identity Authentication SCIM API (in short, SCIM API version 1) **Note** When the property is not defined - Identity Authentication SCIM API is used. • **2** - Identity Directory SCIM API (in short, SCIM API version 2) For more information, see Update Identity Authentication [page 2429].
SAP Concur	`concur.api.version`	• **1** - User v1 API This is the default value for systems created before versioning was introduced on December 8, 2021. • **2** - Identity v4 API This is the default value for systems created between December 8, 2021, and December 1, 2025. • **3** - SCIM v4 API By default, the Identity Provisioning service uses version 3 for all newly created systems starting December 2, 2025, when version 3 was introduced. Systems created earlier continue to follow the previous defaults.
SAP Integrated Business Planning	`ibp.api.version`	• *1* - SAP Integrated Business Planning API: Business User (Version 1) is used. This is the default value. • *2* - Identity v4 API (Version 2) For more information, see Update SAP Integrated Business Planning [page 2432].

Connector	Property	Value
SAP Sales Cloud and SAP Service Cloud	`c4c.api.version`	• **1** - Version 1 (SOAP-based API) > **Note** > The SOAP-based API version 1 is depricated. • **2** - Version 2 (SOAP-based API) • **3** - Version 3 (SCIM 2.0 based API) • **4** - Version 4 (SCIM 2.0 based API) applicable for SAP Sales Cloud Version 2 and SAP Service Cloud Version 2 only
SAP SuccessFactors	`sf.api.version`	• **1** - SAP SuccessFactors HCM Suite OData API (Version 1) > **Note** > When the property is not defined - SAP SuccessFactors HCM Suite OData API is used. • **2** - SAP SuccessFactors Workforce SCIM API (Version 2)
SAP Analytics Cloud	`sac.api.version`	• **1** - SAP Analytics Cloud SCIM API version 1. This is the default value. • **2** - SAP Analytics Cloud SCIM API version 2
SAP S/4HANA Cloud Public Edition	`s4hana.cloud.api.version`	• **1** - SAP S/4HANA Cloud Public Edition API: Business User is used. This is the default value. • **3** - System for Cross-domain Identity Management (SCIM) API is used. For more information, see Update SAP S/4HANA Cloud Public Edition [page 2435].
LDAP Server	`ldap.api.version`	• *1* - LDAP Server API version 1 is used. This is the default value. • *2* - LDAP Server API version 2 is used.

Connector	Property	Value
Microsoft Active Directory	`ldap.api.version`	• *1* - LDAP API version 1 is used. This is the default value. • *2* - LDAP API version 2 is used.

2. **Properties with Version-Specific Values** - Update connector properties which have version-specific values and configure any new properties introduced in the updated version.

Connector	Property	Value
SAP SuccessFactors	`URL`	• Version 1: `https://apitest.successfactors.com/odata/v2` • Version 2: `https://apitest.successfactors.com`
	`sf.user.filter`	• Version 1: **`username eq 'cbraun' status eq 'active'`** • Version 2: **`userName eq "cbraun" active eq true`**
SAP Analytics Cloud	`csrf.token.path`	• Version 1: `/api/v1/scim/Users?count=1` • Version 2: `/api/v1/scim2/Users?count=1`

SAP Integrated Business Planning	`ibp.user.unique.attribute`	• Version 1:
		  • `personExternalID`
		  • `emails[0].value`
		• Version 2:
		  • `userName`
		  • `emails[0].value`
		  • `externalId`

SAP S/4HANA Cloud Public Edition	`s4hana.cloud.user.unique.attribute`	• Version 1:
		  • `personExternalID`
		  • `emails[0].value`
		• Version 3:
		  • `userName`
		  • `emails[0].value`
		  • `externalId`

Connector	Property	Value
SAP Concur	`concur.user.unique.attribute`	Version 1 and 2: • `userName` • `externalId` Version 3: • `userName` • `externalId` • `urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:employeeNumber`
	`concur.user.filter`	Version 1 and 2: • **`userName eq "johnsmith@example.com"`** • **`companyId eq "aa067ada-71a9-4f57-8e98-9300b1c3171d"`** Version 3: • **`userName eq "JohnSmith"`** • **`userName sw "John"`** • **`urn:ietf:params:scim:schemas:extension:enterprise:2.0:employeeNumber eq "00102345"`**

4. On the *Transformations* tab, if you've customized your transformation logic, copy and save it first, and then replace it with the default transformation provided for the respective API version. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.
5. Reset the system [page 2485] to clear the operational data. It is assumed that you have already run provisioning jobs to target systems.
   - If you reset a target system, set the `ips.delete.existedbefore.entities` to **true** in the target system itself. This ensures that, if from now on you delete entities in the source system that is connected to your target system, those entities will be recognized as previously existed entities in the target system and will be deleted there.
   - If you reset a source system, set the `ips.delete.existedbefore.entities` to **true** in every target system connected to the given source system. This ensures that, if from now on you delete entities in the source system that is connected to your target system, those entities will be recognized as previously existed entities in the target system and will be deleted there.
6. Adapt your new transformation, that is, apply the customizations from your previous transformation.
7. Save your changes and run a provisioning job.

1.7.13.6.1 Update Identity Authentication

Update the Identity Authentication connector to a new version.

Following the deprecation of the Identity Authentication SCIM API (SCIM API v1), the API will be decommissioned on **November 30, 2028**. You must migrate to its successor, the Identity Directory SCIM API (SCIM API v2). This migration requires updating all Identity Authentication provisioning systems (source, target, and proxy) from connector version 1 to connector version 2.

> **Note**
>
> Migrate each provisioning system separately and complete one migration before proceeding to the next.

Prerequisites

- When Identity Authentication is the source system (connector version 1) and you want to update its version: Verify that the last provisioning job for the Identity Authentication source system using SCIM API v1 completes successfully before starting the update.
- When Identity Authentication is the target system (connector version 1) and you want to update its version: Verify that the last provisioning job for the source systems completes successfully before starting the update.

> **Note**
>
> The update requires a system reset. If the last provisioning job has failed entities in the source system, resolve them before proceeding. Otherwise, Identity Provisioning will not be able to remove them from the target system after the update, and obsolete users may remain indefinitely.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.

   > **Note**
   >
   > Repeat the steps below for each Identity Authentication source, target, and proxy system.

2. From the list on the left, select your system of type *Identity Authentication*.
3. Select the *Properties* tab and add the following property `ias.api.version`=2.

   > **Note**
   >
   > The property prefix depends on the SCIM API version being used.
   >
   > - For SCIM API v2, property names use the `ias` prefix. For example: `ias.user.unique.attribute`
   > - For SCIM API v1, property names use the `scim` prefix. For example: `scim.user.unique.attribute`

   When migrating from SCIM API v1 to SCIM API v2, ensure that all configuration properties using the `scim` prefix are updated to their corresponding `ias`-prefixed properties.
   In addition, configure the following Identity Provisioning properties:

   - `ips.application.id=<application_ID>`
     The ID of the application created under *Applications & Resources* for the corresponding Identity Authentication provisioning system.
   - `ips.delete.existedbefore.entities=true`
     This property must be set for all Identity Authentication target systems.
   - `ias.support.patch.operation=true`
     This property must be set for all Identity Authentication target systems.
   - `ias.user.automatic.conflict.resolution=true`

This property must be set for all Identity Authentication target systems.

For more information, see List of Properties [page 80].

4. Select the *Transformations* tab and update the user and group attribute mappings that have changed in SCIM API v2 as explained in Attributes Mapping.

Example

Replace the following targetPath:

`$.mailVerified` with `$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']`

In addition to updating existing mappings, review the default transformations delivered for SCIM API v2 and add newly supported attributes that are not present in your current configuration. The Identity Authentication connector documentation provides default transformation mappings for both SCIM API v1 and SCIM API v2.
Compare the mappings and include the additional SCIM API v2 attributes required for your scenario.

Example

Examples of attributes that may need to be added when migrating to SCIM API v2 include:

Code Syntax

```
{

"condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']",

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId']"
      },
      {

"condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
        "sourcePath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']",
        "optional": true,
        "targetPath": "$
['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']"
      },
      {

"condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['supportedOperations']"
      },
      {

"condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
```

```
"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']"
      },
      {

"condition": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",

"sourcePath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalLocation']",
        "optional": true,

"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalLocation']",
        "scope": "createEntity"
      }
```

If your provisioning system uses customized transformations, manually compare them with the SCIM API v2 default transformations to ensure that both updated and newly supported attributes are included after the migration.

For more information on the default transformations, see:

- Identity Authentication source system
- Identity Authentication target system
- Identity Authentication proxy system

5. Reset the system. This is necessary because it is assumed that you have already run provisioning jobs to the target systems.
6. Save your changes and run a provisioning job.

1.7.13.6.2 Update SAP Integrated Business Planning

Update the SAP Integrated Business Planning connector to a new version.

The SAP Integrated Business Planning connector supports two versions, corresponding to the APIs used for integration with Identity Provisioning:

- **Version 1**: Uses the SOAP-based API provided through the communication scenario SAP_COM_0193.
- **Version 2**: Uses the SCIM-based API provided through the communication scenario SAP_COM_0465.

Updating the connector to version 2 depends on your provisioning flow, specifically whether the SAP Integrated Business Planning system is configured as a source or a target system in that flow.

Update Source System

> **Note**
>
> If you have only an SAP Integrated Business Planning source system, or if it is connected in a flow with a target system such as Identity Authentication version 2 or Local Identity Directory, always start the update from the source system.

Proceed as follows:

1. Open your SAP Integrated Business Planning source system and verify that it is configured for version 1. The system is on version 1 if the `ibp.api.version` property is either not set or set to `1`.
2. Select the *Properties* tab and set the following:
   - *ibp.api.version*=2
   - *ips.application.id*=`<The ID of the application that is created under Applications & Resources for the corresponding SAP Integrated Business Planning provisioning system.>`
3. Select the *Transformations* tab and replace the read transformation with the default transformation provided for version 2. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.
4. Reset the source system. This is necessary because it is assumed that you have already run provisioning jobs to the target systems.
   The reset will clear the operational data. After the reset, running subsequent provisioning jobs will update the existing users and groups instead of creating new ones.
5. Open the target system that is connected to your source system (Identity Authentication version 2 or Local Identity Directory). Select the *Transformations* tab and add the mapping for `externalName` if it is missing:

```
{
   "condition":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
   "sourcePath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']",
   "optional":true,
   "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']"
}
```

6. Open the source system and run a provisioning job.
7. Open the target system, select the *Properties* tab and add the properties for handling conflict resolution for the respective target system and the property for deleting entities.
   - *ias.group.unique.attribute*=`['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`
   - *idds.group.unique.attribute*=`['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`
   - *ips.delete.existedbefore.entities*=`true`
     When you reset a source system, this property must be configured in every connected target system. This ensures that if you later delete entities in the source system, those entities are recognized as previously existing in the target system and are deleted there as well.

Result: Following a successful run, it is expected that business roles are provisioned as groups of type `Authorization` for the respective application in SAP Cloud Identity Services, as well as new user groups are successfully created as groups of type `User Group`.

Update Target System

You have an SAP Integrated Business Planning version 1 target system, that is connected with source systems such as Identity Authentication version 2 or Local Identity Directory.

Proceed as follows:

1. Open your source system, respectively Identity Authentication version 2 or Local Identity Directory and ensure that it has the following mapping for `externalName` attribute.

   ```
   {
      "sourcePath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
   ['externalName']",
      "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
   ['externalName']",
      "optional":true
   }
   ```

   > ### Note
   >
   > Groups in Identity Authentication version 2 or Local Identity Directory source systems must have the `externalName` attribute to be provisioned successfully to an SAP Integrated Business Planning version 2 target system.

2. Open the SAP Integrated Business Planning version 1 target system and set the following on the *Properties* tab:
   - *ibp.api.version*=`2`
   - *ibp.group.unique.attribute*=`externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`
   - *ips.application.id*=`<The ID of the application that is created under Applications & Resources for the corresponding SAP Integrated Business Planning provisioning system.>`
   - *ips.delete.existedbefore.entities*=`true`
     When you reset the target system (in step 4), this property will ensure that if you later delete entities in the source system, those entities are recognized as previously existing in the target system and are deleted there as well.
   - Remove unnecessary properties that are valid for SAP Integrated Business Planning version 1.
3. Select the *Transformations* tab and replace the write transformation with the default transformation provided for version 2. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.
4. Reset the target system. This is necessary because it is assumed that you have already run provisioning jobs to the target systems.
   The reset will clear the operational data. After the reset, running subsequent provisioning jobs will update the existing users and groups instead of creating new ones.
5. Open the source system and run a provisioning job.

Update Proxy System

Proceed as follows:

1. Open your SAP Integrated Business Planning proxy system and verify that it is configured for version 1. The system is on version 1 if the `ibp.api.version` property is either not set or set to `1`.
2. Select the *Properties* tab and set the following:
   - *ibp.api.version*=2
   - Remove unnecessary properties that are valid for SAP Integrated Business Planning version 1.
3. Select the *Transformations* tab and replace the proxy read and proxy write transformations with the default transformations provided for version 2. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.

1.7.13.6.3 Update SAP S/4HANA Cloud Public Edition

Update the SAP S/4HANA Cloud Public Edition connector to a new version.

The SAP S/4HANA Cloud Public Edition connector supports two versions, corresponding to the APIs used for integration with Identity Provisioning:

- **Version 1**: Uses the SOAP-based API provided through the communication scenario SAP_COM_0193.
- **Version 3**: Uses the SCIM-based API provided through the communication scenario SAP_COM_0465.

Updating the connector to version 3 depends on your provisioning flow, specifically whether the SAP S/4HANA Cloud Public Edition system is configured as a source or a target system in that flow.

Update Source System

> **Note**
>
> If you have only an SAP S/4HANA Cloud Public Edition source system, or if it is connected in a flow with a target system such as Identity Authentication version 2 or Local Identity Directory, always start the update from the source system.

Proceed as follows:

1. Open your SAP S/4HANA Cloud Public Edition source system and verify that it is configured for version 1. The system is on version 1 if the `ibp.api.version` property is either not set or set to `1`.
2. Select the *Properties* tab and set the following:
   - *s4hana.cloud.api.version*=3
   - *ips.application.id*=`<The ID of the application that is created under Applications & Resources for the corresponding SAP S/4HANA Cloud Public Edition provisioning system>`.
3. Select the *Transformations* tab and replace the read transformation with the default transformation provided for version 3. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.

4. Reset the source system. This is necessary because it is assumed that you have already run provisioning jobs to the target systems.
   The reset will clear the operational data. After the reset, running subsequent provisioning jobs will update the existing users and groups instead of creating new ones.
5. Open the target system that is connected to your source system (Identity Authentication version 2 or Local Identity Directory). Select the *Transformations* tab and add the mapping for `externalName` if it is missing:

```
{
   "condition":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['applicationId'] EMPTY false",
   "sourcePath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']",
   "optional":true,
   "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']"
}
```

6. Open the source system and run a provisioning job.
7. Open the target system, select the *Properties* tab and add the properties for handling conflict resolution for the respective target system and the property for deleting entities.
   - *ias.group.unique.attribute*=`['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`
   - *idds.group.unique.attribute*=`['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['externalName'],['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['applicationId']`
   - *ips.delete.existedbefore.entities*=`true`
     When you reset a source system, this property must be configured in every connected target system. This ensures that if you later delete entities in the source system, those entities are recognized as previously existing in the target system and are deleted there as well.

Result: Following a successful run, it is expected that business roles are provisioned as groups of type `Authorization` for the respective application in SAP Cloud Identity Services, as well as new user groups are successfully created as groups of type `User Group`.

Update Target System

You have an SAP S/4HANA Cloud Public Edition version 1 target system, that is connected with source systems such as Identity Authentication version 2 or Local Identity Directory.

Proceed as follows:

1. Open your source system, respectively Identity Authentication version 2 or Local Identity Directory and ensure that it has the following mapping for `externalName` attribute.

```
{
   "sourcePath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']",
   "targetPath":"$['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']
['externalName']",
   "optional":true
```

```
}
```

> **Note**
>
> Groups in Identity Authentication version 2 or Local Identity Directory source systems must have the `externalName` attribute to be provisioned successfully to an SAP S/4HANA Cloud Public Edition version 2 target system.

2. Open the SAP S/4HANA Cloud Public Edition version 1 target system and set the following on the *Properties* tab:
   - *s4hana.cloud.api.version*=3
   - *s4hana.cloud.group.unique.attribute*=`externalId, ['urn:ietf:params:scim:schemas:extension:sap:2.0:Group']['type']`
   - *ips.application.id*=`<The ID of the application that is created under Applications & Resources for the corresponding SAP S/4HANA Cloud Public Edition provisioning system>`
   - *ips.delete.existedbefore.entities*=`true`
     When you reset the target system (in step 4), this property will ensure that if you later delete entities in the source system, those entities are recognized as previously existing in the target system and are deleted there as well.
   - Remove unnecessary properties that are valid for SAP S/4HANA Cloud Public Edition version 1.
3. Select the *Transformations* tab and replace the write transformation with the default transformation provided for version 3. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.
4. Reset the target system. This is necessary because it is assumed that you have already run provisioning jobs to the target systems.
   The reset will clear the operational data. After the reset, running subsequent provisioning jobs will update the existing users and groups instead of creating new ones.
5. Open the source system and run a provisioning job.

Update Proxy System

Proceed as follows:

1. Open your SAP S/4HANA Cloud Public Edition proxy system and verify that it is configured for version 1. The system is on version 1 if the `s4hana.cloud.api.version` property is either not set or set to `1`.
2. Select the *Properties* tab and set the following:
   - *s4hana.cloud.api.version*=3
   - Remove unnecessary properties that are valid for SAP S/4HANA Cloud Public Edition version 1.
3. Select the *Transformations* tab and replace the proxy read and proxy write transformations with the default transformations provided for version 3. Use the Identity Provisioning connector documentation as a source of information for the transformation you need.

1.7.13.7 Manage Properties

You can add, delete and modify properties for a system in Identity Provisioning.

Prerequisites

You have added a system (source, target, or proxy) in the Identity Provisioning user interface. To learn how, see Add New Systems [page 2415].

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Select a system from the left panel and go to the *Properties* tab.
3. To modify the current properties, choose *Edit* in the bottom right corner.

   > **Note**
   >
   > When you update the URL or the host name of an existing provisioning system, you must re-enter the values of the configured credential properties. The only exception to this are the credential properties of systems that are created with a connectivity destination.

4. Add the properties required by your scenario to make successful connection to the selected system. You can use two types of properties:
   - *Standard*: These are properties, whose values are displayed as numbers or plain text strings. For example: **Type**, **ProxyType**, **URL**, **Authentication**.
   - *Credential*: These are properties whose values contain sensitive information that must not be displayed as plain text. For example: **Password** (standard passwords, private keys, or OAuth client secrets), **ssh.private.key** (relevant to SSH Server).

     > **Note**
     >
     > Properties whose values contain sensitive information can be added only as *Credential* in the Identity Provisioning UI. The values of these properties are stored as encrypted data. They are excluded from the file during system configuration export.

5. Save your changes.

1.7.13.8 Manage Transformations

You can manage transformations with graphical and JSON text editor. Regardless of which one you choose, the following initial steps are the same.

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Select a system from the left panel and go to the *Transformations* tab.
   The graphical editor is displayed by default. You can switch to the JSON editor by choosing the code-bracket icon.
3. Choose *Edit*. You need to work in edit mode to add, modify and delete entities and their configurations.

   > **Note**
   >
   > When editing the transformations, if you add an entity - such as a user, group or role - that is not supported for the given system type, the related configurations may be accepted but will not be applied.

   - Working with the JSON editor allows you to type changes and perform operations like select, cut, copy and paste the transformation code.
   - Working with the graphical editor allows you to graphically model your changes.
4. Save your changes.

1.7.13.8.1 Working with Graphical Editor

You can create, update and delete entities and their attribute mappings with a handy and easy to use graphical editor. It provides typical operations for an editor, like adding new data, editing and deleting existing data and saving changes. And what's more, it brings improved user experience, requires less typing and more choosing from a list of prefilled values.

Basic Operations

> ⓘ Note
>
> The graphical editor is available only for Identity Provisioning tenants running on SAP Cloud Identity infrastructure. It is the default editor.

> **Note**
>
> By default, the transformation opens in the graphical editor. However, the availability of the graphical editor depends on the total number of mappings across all entities. The JSON editor is always available.
>
> - 500 mappings or fewer: Both the graphical and JSON editors are available, and you can switch between them.
> - More than 500 mappings: The transformation can be viewed and edited only in the JSON editor. Switching to the graphical editor is not supported.

Description	Operation
Switch Editor When selecting the *Transformations* tab, the graphical editor is displayed by default. It is represented by a tree icon (in the red rectangle). You can switch to the JSON text editor by choosing the code-bracket icon. Switching between editors is allowed in view and edit mode.	
Description	Operation
Edit Entity > *user/group* > *Ignore Entity* Use this option to ignore the provisioning of an entity. When selected, a check mark appears in front of the option and the entity is greyed out. To enable it again, deselect the option. *Edit Entity* > *user/group* > *Add mapping* Use this option to add attribute mapping for an entity. When selected, the *Add Mapping* dialog appears. For more information, see Add or Edit Attribute Mappings. New mappings are added at the end of the list of mappings for the selected entity. As the order matters, you can move them up and down to define the proper place for processing them. *Edit Entity* > *user/group* > *Add condition* Use this option to add a condition for an entity. When selected, the *Add Condition* dialog appears. You need to provide a value. Conditions defined on an entity level are displayed right under the entity name in orange box. *Edit Entity* > *user/group* > *Add skipOperation* Use this option to add skipOperation for an entity. It is always defined on an entity level and in target system transformations only. When selected, the *Add skipOperation* dialog appears with a dropdown list of prefilled values. *Edit Entity* > *user/group* > *Add scimEntityEndpoint* Use this option to add the entity endpoint which is needed in proxy systems only. *Edit Entity* > *user/group* > *Delete Entity* Use this option to delete an entire entity. Confirmation is required. When an entity is deleted, you cannot restore it. You can only add a new one.	
Description	Operation
Add Entity **Note** The *Add Entity* button is displayed only if an entity has been deleted. When selected, an *Add Entity* dialog appears. You are allowed to select only an entity of the type that has been deleted. The new entity appears in its dedicated colored box and has no content.	Filter The *Filter* icon allows you to search for entity attributes by their scope: create, patch and delete. Filtering is enabled only in view mode, meaning you must not choose *Edit* on the *Transformations* tab. When selected, the *Filter* dialog appears with the default value *(Not Filtered)*. Selecting a filter results in returning all entity attributes with the given scope plus all attributes without any scope. **→ Remember** Attribute mappings with no scope are always returned regardless of the selected filter. Choosing *Reset* returns you to the default value *(Not Filtered)*.	Operations on an attribute mapping level: - *Pencil* icon - Edit an attribute mapping - *Trash* icon - Delete an attribute mapping - *Plus* sign icon - Adds an attribute mapping - *Function* icon - Add or edit a function Functions appear only for attributes on the right side of the editor. - *Pencil* icon - Edit value mappings This icon appears only for attributes with `type` set to `valueMapping`, for example: `businessPartnerRoleCode`, `timezone` and others. - *Up arrow* icon - Move an attribute mapping one level up. - *Down arrow* icon - Move an attribute mapping one level down.	
Add or Edit Attribute Mappings

When you select *Add mapping* for an entity or choose the *Plus* icon next to an attribute, the *Add Mapping* or *Edit Mapping* dialog appears, respectively. Use it to configure the following:

- Add *Mapping Paths* - A mapping path is a name-value pair (that is, source and target path expressions and their values) based on a selected type of value.
  In the *Name* field, you can choose one of the predefined `sourcePath` and `targetPath` expressions, select your *Type* of value: *attribute*, *property* or *value* and finally, provide the value itself.
  Attribute is the default type value.
  If you want to configure a complex attribute, for example **`name.familyName`**, add the **`name`** attribute first and then choose the *Plus* sign icon to add the **`familyName`** subattribute second. You can add as many subattributes as you need.
- Add *Mapping Configurations* - A mapping configuration is a name-value pair (that is, a transformation expression and its value).
  In the *Name* field, you can choose one of the predefined expressions: *condition*, *scope*, *constant*, *ignore*, *correlationAttribute* and others, define the data type by selecting *Type* and provide a value.
  Some expressions have predefined types and values. For example, ignore and optional are always set with Boolean data type and have true or false as predefined values. The skipOperations are always set with String data type and have: create, update and delete as predefined values.
- View your configuration in the *Mapping Representation in JSON* view.

Add or Edit Functions

When you choose the *Function* icon on an attribute mapping level, the *Add Functions* dialog appears. If a function is already configured for a mapping, the *Edit Functions* dialog appears. Use it to configure the following:

- Choose *Add* > *Function* and select one from the list.
  Most functions have predefined parameters, listed in the *Name* field. For example, if you add the `replaceLastString` function, the `regex` and `replacement` parameters are prefilled. You only need to provide a value.
  If no parameters are listed in the *Name* field, choose *Add* next to the selected function to add a name-value pair.
  You can add as many functions as you need. The number of functions you've added is displayed under the title of the dialog.
- Order the functions if needed. As the order of the functions matter, you can choose the arrows to move them up and down to define the proper place for processing them.

1.7.13.8.2 Enabling Group Assignment

When provisioning users from source to target systems, in addition to replicating the user data, you can also assign them to groups in the target system. This works for standard provisioning with or without configured bulk operation on the target, and real-time provisioning.

Prerequisites

- You have one of the following target systems configured:
  - Identity Authentication [page 937]
  - Local Identity Directory [page 957]
  - Microsoft Entra ID [page 1323]
  - SAP Advanced Financial Closing [page 966]
  - SAP Analytics Cloud [page 975]
  - SAP Ariba Applications [page 1003]
  - SAP Ariba Central Invoice Management [page 1016]
  - SAP BTP ABAP environment [page 1021]
  - SAP Build Work Zone, standard edition [page 1062]
  - SAP BTP XS Advanced UAA (Cloud Foundry) [page 1045]
  - SAP Commerce Cloud [page 1079]
  - SAP Concur [page 1085]
  - SAP Data Custodian [page 1113]
  - SAP Enable Now [page 1129]
  - SAP Field Service Management [page 1140]
  - SAP HANA Cloud Database Services [page 1145]
  - SAP Integrated Business Planning [page 1157]
  - SAP Intelligent Agriculture [page 1175]
  - SAP Marketing Cloud [page 1196]
  - SAP Revenue Growth Management [page 1205]
  - SAP Sales Cloud and SAP Service Cloud [page 1211]
  - SAP S/4HANA Cloud Public Edition [page 1234]
  - SAP SuccessFactors Employee Central Payroll [page 1279]
  - SAP SuccessFactors Incentive Management [page 1284]
  - Cloud Foundry UAA Server [page 1295]
  - SCIM System [page 1335]
- The groups that you want to assign exist on the target system.

Context

To enable the group assignment, you need to modify the target system transformation by adding a mapping under the user resource containing the following configuration parts:

- **Condition** - Defines for which users the condition will apply. For example, all users with emails.
- **Constant** - Holds the IDs of the groups in the target system. Currently, you can only identify groups by ID.
- **targetVariable** - Specifies whether you want to assign users to groups or unassign users from groups.

Assign Users to Groups

This mapping will result in assigning all users with emails to two groups in a target system.

Code Syntax

```
{
   "user":{
      "mappings":[

<Existing transformation>
{
            "condition":"($.emails
EMPTY false)",
            "constant":[
               {
                  "id":"00f8ab94-
a732-48fa-9169-e51f87b8dcd5"
               },
               {

"id":"01231139-4711-4a28-8f9d-67458
43ef716"
               }
            ],

"targetVariable":"assignGroup"
         }
      ]
   },
   "group":{
      "mappings":[
```

Unassign Users from Groups

This mapping will result in unassigning all users with emails from two groups in a target system.

Code Syntax

```
{
   "user":{
      "mappings":[
<Existing transformation>
{
            "condition":"($.emails
EMPTY false)",
            "constant":[
               {

"id":"006aeaea-3486-479e-8c65-
eabd2868653e"
               },
               {

"id":"00bbae67-6b9d-4f46-9306-6aad2
8c40861"
               }
            ],

"targetVariable":"unassignGroup"
         }
      ]
   },
   "group":{
      "mappings":[
```

Groups which are assigned to users through the user resource are referred to as user managed groups. Following a successful provisioning, if the user managed groups are managed through the group resource, the assignments made through the user managed groups will be overwritten.

Note

If the group doesn't exist in the target system during user creation or update, the user provisioning fails.

If the group doesn't exist in the target system during user deletion, the user deletion succeeds.

> **Note**
>
> If you use different conditions within the group assignment mappings and the same user matches more than one condition, only the last matching condition is applied. As a result, only the groups defined in the last condition are assigned to the user.

If you want to remove the group assignments of a deleted user from the source system, you need to modify the target system transformation by adding a mapping under the user resource containing the following configuration parts:

- **Constant** - Holds the IDs of the groups in the target system which will be updated. Currently, you can only identify groups by ID.
- **targetVariable** - Use **`"unassignGroup"`** to specify that you want to unassign users from the defined groups.
- **scope** - Use **`"deleteEntity"`** to define that the deleted user from the source system should be persisted in the target system. For detailed information depending on the target system in use, see Transformation Expressions [page 391] → `deleteEntity`.

```
{
    "constant": [
        {
            "id": "groupID"
        }
    ],
    "targetVariable": "unassignGroup",
    "scope": "deleteEntity"
}
```

This mapping will result in updating the assignments to the defined group in the target system.

> **Note**
>
> If you try to assign or unassign a user managed group to a user for a provisioning system that does not support it and trigger a provisioning job, the entity will fail and the job will finish with error.

When using the group unassignment for users that are deleted from the source system, these are the possible scenarios based on the system where the user was created and the value of the property `ips.delete.existedbefore.entities`:

- When the user was provisioned from another system by the Identity Provisioning service or it was initially created in the target system and the property `ips.delete.existedbefore.entities` is set to **`true`** In this case only transformation mappings for the affected user containing scope `deleteEntity` are executed. This mapping could be used, for example, for disabling a user account in the target system. For more information, see Transformation Expressions [page 391] → `deleteEntity`.

  > **Note**
  >
  > The update is executed via PUT or PATCH operation, based on the configuration of the property `*.support.patch.operation` in the target system.

- When the user was initially created in the target system and the property `ips.delete.existedbefore.entities` is set to **`false`**, the group assignments of the user in the target system will be updated.

1.7.13.8.3 Manage Transformations History

Manage the history of transformations, review and restore them to a previous version of your choice.

> **Note**
>
> This functionality is available for Identity Provisioning tenants running on SAP Cloud Identity infrastructure.

Context

Every time you modify the transformation of a provisioning system and save your changes, a new version is created and displayed in the *Transformation History* screen. It lists all versions - from the initial to the current one, and gives you additional information about the last modification date, the person who modified it and a description. Within this screen, you can perform a number of actions: reset the transformation to its initial version, apply the current default transformation or apply a version of your choice, as well as download previous versions of the transformations for the current system. In case you need to compare two or more versions, you can do it in a text editor, once you download the respective versions.

Transformation History

Column	Description
Version	Transformation version **Note** Version 1 is the initial version. The version with the highest number is the current version. The **initial version** is the one that you get when the system is created (manually or automatically). If you don't make any changes to the transformation while creating the system, the initial transformation matches the default one. If you or a provisioning tool make changes to the transformation while creating the system, the initial transformation doesn't match the default one. There is no restriction on the number of versions you can store and manage. By default, 20 versions are displayed on the screen. You need to expand the list until all your versions are displayed.
Last Modified	Date and time the transformation was last modified
Modified By	Who modified the transformation: • The userID of the person who modified the transformation • *SAP* - Indicates that this transformation has been migrated by SAP. This could be your initial transformation or your current one.
Description	(Mandatory) Description of the changes When modifying the transformation, saving your changes is only allowed if you provide a description. **→ Recommendation** Keep the transformation change description as short as possible. Note that some languages and special characters may consume more space than others.
Actions	Actions you can perform for a selected version: • Apply the selected version. This restores the transformation to the selected version. • Download the selected version.
Default Version	Apply the current default version.
Reset to Initial	Reset the transformation to its initial version.

Following the introduction of transformations history on November 27, 2023, all your systems will have initial version listed in the *Transformation History*. What this initial version means for you, however, depends on the release of the reset transformation functionality on November 1, 2021. And that is because with implementing the reset, Identity Provisioning began storing the initial version of modified transformations.

- Systems created before November 1, 2021, will get the current transformation as initial version.
- Systems created after November 1, 2021, will get their actual initial transformation (the one they got at system creation) as initial version. If this transformation has been changed, the *Transformation History* will also list the current transformation as version 2.
- As of November 27, 2023, every newly created system is created with initial version. Disabled systems will get the initial version upon enabling them.

> **Note**
>
> Deleting a system or resetting the tenant results in deleting the transformation history. Resetting the system itself does not delete the history.

Procedure

To manage your transformations history and apply the version you need, proceed as follows:

1. Sign in to SAP Cloud Identity Services administration console and navigate to *Identity Provisioning*.
2. Select a system under *Source Systems*, *Target Systems* or *Proxy Systems* and choose the *Transformations* tab.
   If the transformations have been modified, an info message is displayed in the message view.
3. Select the *Edit* button and choose the clock icon.
   This opens the *Transformation History* screen.
   Without entering the edit mode, you are only allowed to view the transformation versions and download them.
4. Choose the action that you want to execute.
5. Choose *Close*.

1.7.13.9 Manage Certificates

Identity Provisioning supports certificate-based authentication for secure communication with the provisioning systems (connectors) provided by the service.

Context

Certificates can be used in outbound and inbound connections to Identity Provisioning.

In **outbound connections**, Identity Provisioning acts as an SSL client. The service generates an X.509 client certificate for mutual Transport Layer Security (mTLS) authentication against a given provisioning system acting as a server. The Identity Provisioning client certificate must be uploaded to the given provisioning

system for configuring the certificate-based authentication there. For example, in SAP BTP ABAP Environment, the Identity Provisioning certificate must be uploaded to the communication user used in the communication arrangement.

> **Note**
>
> Outbound certificates generated by Identity Provisioning can also be used for OAuth authentication with provisioning systems. In OAuth certificate authentication, Identity Provisioning acts as a client application that sends requests to the URL of the access token provider service (the authorization server). The server issues access tokens following a successful authentication with certificate (instead of using client ID and client secret).
>
> Currently, OAuth certificate authentication is supported for SAP Business Network and Procurement Data Warehouse.

In **inbound connections**, Identity Provisioning acts as a server whereas the given provisioning system acts as a client and must present a client certificate for establishing the communication to the service. Customers of bundle and standalone tenants running on SAP BTP, Neo environment import client certificates in the Identity Provisioning admin console. Customers of bundle and standalone tenants running on SAP Cloud Identity infrastructure upload the client certificates in the Identity Authentication admin console on the technical user of type *System*.

Inbound certificates are supported for source and proxy systems in the following scenarios: configuring proxy systems and real-time provisioning.

> **Note**
>
> Client certificate authentication is not supported for systems where the *ProxyType* and *ldap.proxyType* properties, required for the HTTP and LDAP connection respectively, are set to `OnPremise`.

> **Note**
>
> If you are using Identity Provisioning proxy and real-time provisioning scenarios, ensure that you trust the new root CA: DigiCert Global Root G2 as the old one DigiCert Global Root CA will be deprecated. For more information, see Root Certificate Replacement.

1.7.13.9.1 Generate and Manage Certificates for Outbound Connection

Identity Provisioning handles the following tasks related to X.509 client certificates for outbound connection: generating, automatic regenerating, activating, deactivating, downloading and deleting.

Administrators can manage up to two certificates for secure outbound connection with a given provisioning system. Only one certificate can be active at a time.

Generating a second certificate might be needed in case your active certificate is about to expire. Currently, renewing or extending the validity of a certificate is handled by generating a second one. This will ensure that the communication between Identity Provisioning and the given provisioning system won't be disrupted.

Both certificates - the first and the second one, have the same distinguished name (DN), issued by the same certificate authority (CA).

Thirty days before the expiration of your active certificate you'll start receiving a warning message in the *Outbound Certificate* tab of your Identity Provisioning user interface (UI). If you allow the certificate to expire, it becomes invalid. It is not possible to extend its validity.

> → Recommendation
>
> Enable *Automatic Regeneration* to ensure your certificate does not expire. This option is supported for tenants running on SAP Cloud Identity Services infrastructure.

You can subscribe to receive notification e-mails for expiration of your outbound certificate. Based on the enablement of the automatic regeneration option, the e-mail provides the following information:

- When the automatic regeneration option is enabled, 14 days prior to the certificate expiration you will receive an e-mail with subject *Outbound Certificate Renewed. <system_type> System: <system_name>* containing details about the regenerated outbound certificate.
- When the automatic regeneration option is not enabled, on the 30th, 14th, and 3rd day before the outbound certificate expiration, you will receive an e-mails with subject *Outbound Certificate Expiration. <system_type> System: <system_name>* containing information about the certificate.

The following table explains the key tasks available:

Task	Description
Automatic Regeneration	Turn automatic regeneration option on or off: • *ON* - enables the automatic regeneration and activation of outbound certificates. The certificate will be automatically regenerated and activated within 14 days prior to its expiration. → Recommendation This option is recommended for systems validating certificates based on their subject and issuer. In such cases, no further manual steps are required. This option is not recommended for systems validating certificates based on fingerprint. When you regenerate the certificate, the fingerprint is changed. This will cause the authentication to fail until the certificate is downloaded and uploaded to the connected system. If your active certificate has expired and you have manually generated a second one without activating it, enabling the automatic regeneration option will result in the following behavior: 1. A new certificate will be generated and set to active. 2. The expired certificate will be set to inactive. 3. The initially inactive certificate will be deleted. • *OFF* - disables the automatic regeneration. Certificate regeneration will not be done automatically, therefore checking certificate expiration and regeneration should be a manual process.
Generate	You can generate a maximum of two certificates. After reaching the limit, the *Generate* button is greyed out. The status of the first certificate you generate is set to *Active*. The status of the second certificate is set to *Inactive*. Certificates are distinguished by their **fingerprints** (the unique identifier of the certificate).
Subscribe	You can subscribe yourself or another user or a group to receive notification e-mails for expiring or automatically regenerated outbound certificates.

Task	Description
Activate	Activate an inactive certificate. → Recommendation We recommend that you activate your certificate after you have uploaded it in the backend provisioning system. This will ensure that the communication between Identity Provisioning and the backend system won't be disrupted. Only one certificate can be active at a time.
Download	You can download both active and inactive certificates.
Expand	You can expand active and inactive certificates to view their details. If a certificate is about to expire, you see a warning message in the details.
Delete	You can delete only inactive certificates.

Generate Certificate

To generate a client certificate, proceed as follows:

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Select your provisioning system and choose *Outbound Certificate* > *Generate*.
   If the certificate is generated successfully, the toast message `Certificate generated successfully` is displayed on the screen.
3. View the certificate information.
   Each certificate contains fields specifying the subject, the name of the CA issuing the certificate, the algorithm used by the issuer to sign the certificate, validity period, key size and the certificate unique identifier.
4. Download the certificate.
5. Log on to the provisioning system you want to authenticate to (in this case, SAP BTP ABAP Environment) and upload the certificate to configure the certificate-based authentication there. For more information, see: How to Create Communication Users
6. Return to the Identity Provisioning UI and select the *Properties* tab of the provisioning system.
7. Set the *Authentication* property to **`ClientCertificateAuthentication`**.
8. Save your configuration.

Manage Certificate Validity

To manage the certificate validity, choose your applicable approach: automatic or manual.

Manage Validity Automatically

Enable the *Automatic Regeneration* option.

The expiring active certificate is set to inactive. A new certificate is automatically regenerated and set to active.

For systems validating certificates based on their subject and issuer, no further manual steps are required.

Manage Validity Manually

1. Periodically check the validity of your active certificate.
2. When the certificate approaches its expiration date (or it has already expired), generate a new certificate, as described above. The status of this certificate will be *Inactive*.
3. Continue with downloading the inactive certificate and uploading it to the backend provisioning system.
4. Once ready, activate the second (inactive) certificate. As a result, your current active certificate will be set to inactive.
5. You can safely delete the inactive certificate.

Subscribe for Expiring Outbound Certificate Notification

To avoid the need of checking manually the validity of your active outbound certificate, you are able to subscribe yourself or another user or a group to receive notification e-mails for its expiration. This way, you will be notified by e-mail on the 30th, 14th, and 3rd day before it expires.

To get subscribed, proceed as follows:

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*, *Target Systems* or *Proxy Systems*.
2. Select the system you need to watch and choose *Outbound Certificates*.
3. Choose *Subscribe*.
   - To subscribe yourself, choose *Subsribe* > *Subscribe me*.
   - To subscribe another user or a group (distribution list), choose *Subscribe others*. Fill in the required fields *Display name* and *E-Mail* and choose *Add*.

     > **Note**
     >
     > From the *Recipients* list, you can remove existing subscribers. To do that, go to the *Action* column and choose the icon.

   - If you no longer need to be subscribed to a source system, choose *Subscribe* > *Unsubscribe me*.

1.7.13.9.2 Manage Certificates for Inbound Connection

Identity Provisioning handles the following tasks related to X.509 client certificates for inbound connection: importing and deleting.

Importing client certificates for inbound connection to Identity Provisioning is used in two scenarios: configuring real-time provisioning and configuring proxy systems for provisioning user data to and from a central identity management solution. Therefore, inbound client certificates can be configured for source and proxy systems only.

Certificate files with the following filename extensions are supported: `.crt`, `.pem` and `.der`.

Depending on the infrastructure/environment your Identity Provisioning tenant is running, you manage the inbound certificates in the administration console of Identity Provisioning or SAP Cloud Identity Services.

SAP Cloud Identity Infrastructure

Bundle or standalone tenants running on SAP Cloud Identity infrastructure manage certificates for inbound connections in the SAP Cloud Identity Services admin console, where the certificate must be uploaded for the technical user of type *System*. For more information, see Add System as Administrator.

If this technical user will be used to connect to Identity Provisioning proxy system, enable the *Access Proxy System API* permission.

1.7.13.9.3 Configure OAuth Certificate Authentication

You can use outbound certificates generated by Identity Provisioning for OAuth authentication with provisioning systems.

In OAuth certificate authentication, Identity Provisioning acts as a client application that sends requests to the URL of the access token provider service (the authorization server). The server issues access tokens following a successful authentication with certificate (instead of using client ID and client secret).

> **Note**
>
> Currently, OAuth certificate authentication is supported for SAP Build Work Zone, advanced edition, SAP CPQ, SAP Business Network and Procurement Data Warehous.

To configure OAuth certificate authentication for communication between Identity Provisioning and a given provisioning system, proceed as follows:

1. Select the *Properties* tab of the provisioning system and make sure the *Authentication* property is set to **`ClientCertificateAuthentication`**.

   > **Note**
   >
   > This authentication method can only be configured using properties. It doesn't work with destinations.

2. Add the *OAuth2TokenServiceURL* property and provide the URL of the access token provider service for your provisioning system.
3. Add the *client_id* property and provide the OAuth Client id used for access token retrieval.
4. Select the *Certificates* tab and generate the certificate for outbound connection, as described in Generate and Manage Certificates for Outbound Connection [page 2452].
5. Log in to the provisioning system and upload the certificate. The specific location may vary depending on the system, but it is typically found in the security or certificate management section.
6. Run a provisioning job.

Results

During the job execution, Identity Provisioning authenticates to the authorization server using the client certificate and gets the access token issued by the server.

1.7.13.10 Configure Form-Based OAuth Authentication

Configure Identity Provisioning to use form-based OAuth 2.0 authentication to call SAP Ariba Applications APIs.

In this authentication scenario, the Identity Provisioning Service uses the OAuth 2.0 client credentials flow to obtain an access token from the Identity Authentication Service. The access token is retrieved using a form-encoded request with a client ID and client secret that are generated for the Administration Console system application of SAP Cloud Identity Services. This token is then used to call the next-generation SCIM API of SAP Ariba Applications.

Prerequisites

- SAP Ariba Applications configuration exists in SAP Cloud Identity Services.
- The required Provided APIs are configured for the SAP Ariba Applications application. For more information, see Provide APIs for Consumption by Other Applications
- A source, target, or proxy system for SAP Ariba Applications is created in Identity Provisioning. For more information, see SAP Ariba Applications (Source [page 641], Target [page 1003], Proxy [page 1450]).

Application Configuration

To enable token retrieval for the next-generation SCIM API of SAP Ariba Applications, a client ID and client secret must be generated in the Administration Console system application under *Trust* > *Application APIs* > *Client Authentication*. These credentials are later used in the SAP Ariba Applications provisioning system properties for the technical user (`User` and `Password`).

For more information, see Configure Secrets for API Authentication.

Additional configuration in the Administration Console system application requires establishing a dependency to the SAP Ariba Applications API. This is maintained under *Trust* > *Application APIs* > *Dependencies*, where the dependency name, the application, and the corresponding API are defined.

For more information, see Integrating Applications Configure Integration Between Applications.

The value provided for the *Dependency Name* is used to identify the API that the consumer application consumes.

> **Note**
>
> The dependency name must match the value of the `<system_prefix>.api.dependency.name` property in the provisioning system configuration.

For more information, see List of Properties [page 80].

Provisioning System Configuration

To configure your SAP Ariba Applications provisioning system, the following properties must be in place:

- `User` - the Client ID generated in the Administration Console system application.
- `Password` - the Client Secret generated in the Administration Console system application.
- `ariba.applications.api.dependency.name` - the dependency name provided in the Administration Console system application.
- `AuthType` - set to Form
- `Authentication` - set to BasicAuthentication
- `OAuth2TokenServiceURL` - the `/oauth2/token` Service URL of Identity Authentication: `https://<Identity Authentication tenant host>/oauth2/token`

1.7.13.11 Manage Full and Delta Read

When you set up your systems and start a scheduled provisioning task, the standard behavior of the process reads all the entities from the source system. This mode prevents data loss and always keeps your target system synchronized with the source. However, it may take a long time for every job to be executed.

Context

Delta read is a concept for optimizing the amount of data retrieved from the source system. Delta read is much faster, but sometimes might have limitations. In order for a source system to support delta read mode, its API should allow the implementation of this feature.

For example, the *Microsoft Active Directory* source system uses the **uSNChanged** attribute. For more information, see Microsoft: Polling for Changes Using USNChanged .

The main difference between delta and full read is:

- *Delta read* – only modified data is read from the source system and triggered to the target one. Modified data means: new entities and updates on existing entities. Entities deleted from the source system will not be deleted from the target. They can be deleted only during a *full read* job.
- *Full read* – all entities (new, updated, deleted, and existing unchanged ones) are read and checked every time a provisioning job is triggered to the target system.

To keep source and target systems completely synchronized, you can use the *Resync* type of provisioning job.

> → Tip
>
> We recommend that you enforce full reads from time to time if the connector is in delta read mode. To achieve this, you need to set up the following source system property: `ips.full.read.force.count`. For example, `ips.full.read.force.count` = **10** will result in alternating full reads after every 10 delta reads are performed.
>
> This property only impacts scheduled runs; manually triggered runs are ignored. In case it is not set, only delta read jobs will be executed.

> → Remember
>
> When the Identity Provisioning reads entities from a source system for the first time, it always triggers a **full read** job. If the job is successful, the service can then continue with delta read jobs (if such are activated).

During a delta read job, the service reads only the entities that are new or have been modified after the last successful job.

> **Note**
>
> Note that Identity Provisioning will not delete entities in the target system if the job runs in **delta read** mode, if entities fail to be read from the source system or if both conditions apply. Deletion is only possible when the job runs in **full read** mode and the entities are successfully read from the source system.
>
> In cases where deletion does not occur automatically, you must decide on the next steps. You can either resolve the failed entities in the source system and run a full read job, or proceed with deletion as described in Manage Deleted Entities [page 2463].

Below are listed all source systems that currently support *delta read* mode.

Supported Systems

System Type	Details
Microsoft Active Directory	Default mode: *Full read* You can switch to delta read, if you set up the relevant property: `ips.delta.read` = **enabled** Bear in mind the following specifics and limitations: • Make sure that the service user, which is used in the AD destination, has a **Domain Admin** role, otherwise the connector won't be able to extract any data from the recycle bin. • Due to the *linked attributes* concept of AD, there is a limitation in the Microsoft Active Directory read connector, when performing in delta read mode. We recommend that you enforce full reads periodically in order to avoid data loss. See: Microsoft: Linked Attributes • You need to set limitations about which particular attributes to be read. For this purpose, set the properties `ldap.user.attributes` and `ldap.group.attributes` and add **uSNChanged** to the attributes list. Otherwise, the provisioning job will run in *full read* mode. • If an entity is moved outside the base path (another directory context), the connector won't recognize this change during delta read.
SAP SuccessFactors	Default mode: *Delta read* You can switch to full read, if you set up the relevant property: `ips.delta.read` = **disabled**
SAP SuccessFactors Learning	Default mode: *Delta read* You can switch to full read, if you set up the relevant property: `ips.delta.read` = **disabled**
Identity Authentication	Default mode: *Full read*

System Type	Details
Intelligent Opportunity Analyzer	You can switch to delta read, if you set up the relevant property: `ips.delta.read` = **enabled** **Note** When using SAP Central Business Configuration and Identity Directory SCIM API (in short, SCIM API version 2), delta read mode is only supported for user resources. For delta read of resources (users and groups), bear in mind the following API requirements: • The system API should return **lastModified**, which is a subattribute of the **meta** attribute. The **lastModified** subattribute denotes the most recent date and time when the resource details were updated at the service provider. See: SCIM: Common Attributes • The system API has to also support filtering by the **lastModified** attribute, and the system should support the **gt** operator in filter expressions. See: SCIM: Filtering

1.7.13.12 Manage Deleted Entities

Manage deletion of entities (users or groups) in the target system after they have been deleted from the source system.

Scenario 1: Entity exists in the source and the target system

An entity exists both in the source and the target system.

1. You run a provisioning job for the first time.
   As a result, Identity Provisioning reads this entity from the source and updates it on the target system.
2. You delete the relevant entity from the source system.
3. You run another provisioning job, which finishes successfully.
   However, the service recognizes the relevant entity as a "previously existed one" and **does not delete** it from the target.

Solution

To delete entities from a target system after they have been deleted from the source system, you need to set the following property: **`ips.delete.existedbefore.entities`** = *true* in the target system. This must be done **before** the job to delete those entities from the target system is executed.

> → Recommendation
>
> The following sequence of steps is recommended for synchronizing deletion of entities between source and target systems, as in **Scenarios 1, 2** and **3**:
>
> You have run successful provisioning jobs (*Read* or *Resync*) between the systems.
>
> 1. Delete an entity from the source system.
> 2. On the *Properties* tab of the target system, add the **`ips.delete.existedbefore.entities`** property and set its value to *true*.
> 3. Run a provisioning job.
> 4. Verify that the relevant entity has been deleted from the target system.

If the property is set **afterwards**, entities recognized as "previously existed ones" cannot be deleted from the target system anymore. In this case, you need to delete them from the target system (for example, manually or via script).

The **`ips.delete.existedbefore.entities`** is an optional property which can be set on every target system. You can use it to control whether recognized entities as "previously existed ones" should be deleted from the target system.

This is important for security and legal reasons in cases when users (for example, employees) are no longer active in the source system, and their availability and permissions must be removed from the relevant target system(s).

For more information about this property, see: List of Properties [page 80], where you can search it by *Name* or use the general table search.

Scenario 2: Entity does not exist in the source and the target system

An entity does not exist in either system (neither source, nor target).

1. You run provisioning jobs (*Read* or *Resync*) between the systems.
2. You add this entity to the source system.
3. The same entity is added (manually or via script) to the target system.
4. You run a new provisioning job.
   As a result, Identity Provisioning reads this entity from the source and updates it in the target system.
5. You delete the relevant entity from the source system.
6. You run another provisioning job, which finishes successfully.
   However, the service recognizes the relevant entity as a "previously existed one" and **does not delete** it from the target.

Solution

To delete entities from a target system after they have been deleted from the source system, you need to set the following property: **`ips.delete.existedbefore.entities`** = *true* in the target system. This must be done **before** the job to delete those entities from the target system is executed.

> → Recommendation
>
> The following sequence of steps is recommended for synchronizing deletion of entities between source and target systems, as in **Scenarios 1, 2** and **3**:
>
> You have run successful provisioning jobs (*Read* or *Resync*) between the systems.
>
> 1. Delete an entity from the source system.
> 2. On the *Properties* tab of the target system, add the **`ips.delete.existedbefore.entities`** property and set its value to *true*.
> 3. Run a provisioning job.
> 4. Verify that the relevant entity has been deleted from the target system.

If the property is set **afterwards**, entities recognized as "previously existed ones" cannot be deleted from the target system anymore. In this case, you need to delete them from the target system (for example, manually or via script).

The **`ips.delete.existedbefore.entities`** is an optional property which can be set on every target system. You can use it to control whether recognized entities as "previously existed ones" should be deleted from the target system.

This is important for security and legal reasons in cases when users (for example, employees) are no longer active in the source system, and their availability and permissions must be removed from the relevant target system(s).

For more information about this property, see: List of Properties [page 80], where you can search it by *Name* or use the general table search.

Scenario 3: Entity exists in the source system only

An entity exists in the source system only.

1. You run at least one provisioning job.
   As a result, Identity Provisioning reads this entity and creates it in the target system.
2. You reset one of these systems. See: Reset Identity Provisioning System [page 2485]
3. You run a new provisioning job.
   As a result, Identity Provisioning reads this entity from the source system (but is not "aware" of it, that is, it behaves like reading it for the first time) and makes a full update of it in the target system.
4. You delete the relevant entity from the source system.
5. You run another provisioning job, which finishes successfully.
   However, the service recognizes the relevant entity as a "previously existed one" and **does not delete** it from the target.

Solution

To delete entities from a target system after they have been deleted from the source system, you need to set the following property: **`ips.delete.existedbefore.entities`** = *true* in the target system. This must be done **before** the job to delete those entities from the target system is executed.

> → Recommendation
>
> The following sequence of steps is recommended for synchronizing deletion of entities between source and target systems, as in **Scenarios 1, 2** and **3**:
>
> You have run successful provisioning jobs (*Read* or *Resync*) between the systems.
>
> 1. Delete an entity from the source system.
> 2. On the *Properties* tab of the target system, add the **`ips.delete.existedbefore.entities`** property and set its value to *true*.
> 3. Run a provisioning job.
> 4. Verify that the relevant entity has been deleted from the target system.

If the property is set **afterwards**, entities recognized as "previously existed ones" cannot be deleted from the target system anymore. In this case, you need to delete them from the target system (for example, manually or via script).

The **`ips.delete.existedbefore.entities`** is an optional property which can be set on every target system. You can use it to control whether recognized entities as "previously existed ones" should be deleted from the target system.

This is important for security and legal reasons in cases when users (for example, employees) are no longer active in the source system, and their availability and permissions must be removed from the relevant target system(s).

For more information about this property, see: List of Properties [page 80], where you can search it by *Name* or use the general table search.

Scenario 4: Entity not created in the target system by Identity Provisioning

An entity exists both in the source and the target system. (It has **not** been created on the target by the Identity Provisioning service.)

Conditions or expressions, such as (*ignore* or *skipOperations*), are not set in the target transformation.

1. You run a successful *Read* job. As a result, Identity Provisioning updates the existing entity on the target system.
2. You delete this entity from the source system.
3. You run a provisioning job, which finishes with error.
   As a result, the relevant entity has not been deleted from the target system.
4. In the job log, you see that there are failed entities (users or groups) on the source system. That means, the job has failed trying to read them from the source.

Solution

1. Resolve the failed entities in the source system.
2. On the *Properties* tab of the target system, add the **`ips.delete.existedbefore.entities`** property and set its value to *true*.
3. Run a successful *Read* job between the systems.
4. Verify that the relevant entity has been deleted from the target system.

> → Tip
>
> Even if the job fails due to errors on the target system, if the read from the source is successful, the service will still delete the entity from the target.

Scenario 5: Entity created in the target system by Identity Provisioning

An entity exists in the source system and has been provisioned to the target by the Identity Provisioning service.

Conditions or expressions, such as (*ignore* or *skipOperations*), are not set in the target transformation.

1. You delete this entity from the source system.
2. You run a provisioning job, which finishes with error.
   As a result, the relevant entity has not been deleted from the target system.
3. In the job log, you see that there are failed entities (users or groups) on the source system. That means, the job has failed trying to read them from the source.

Solution

1. Resolve the failed entities in the source system.

2. Run a successful *Read* job between the systems.
3. Verify that the relevant entity has been deleted from the target system.

> → Tip
>
> Even if the job fails due to errors on the target system, if the read from the source is successful, the service will still delete the entity from the target.

Scenario 6: Delta read job has been run

An entity exists in the source system and has been provisioned to the target by the Identity Provisioning service.

Conditions or expressions, such as (*ignore* or *skipOperations*), are not set in the target transformation.

1. You delete an entity from the source system.
2. You run a **delta read** job, which finishes successfully.
   However, the relevant entry has not been deleted from the target system. That's because *delta read* jobs do not take deleted users into consideration. To learn more, see: Manage Full and Delta Read [page 2459]

Solution

1. On the *Properties* tab of the source system, set the `ips.delta.read` property to *false*.
   Alternatively, you can wait for the next scheduled *full job* to start (if it's coming soon), according to the number you have set for property `ips.full.read.force.count`.
2. Run a new provisioning job (or wait for it to run automatically). It will be a *full read* job.
3. Verify that the relevant entity has been deleted from the target system.
4. (Optional) If you want to continue running *delta read* jobs, go to the `ips.delta.read` property and set it back to *true*.

1.7.13.13 Connect to On-Premise Systems

Set up the connection to on-premise systems when your Identity Provisioning bundle or standalone tenant is running on the infrastructure of SAP Cloud Identity Services.

Prerequisites

- You have installed the Cloud Connector (for SAP BTP multi-environment subaccount), and have done the initial configuration. For more information, see Cloud Connector.

Context

If your provisioning scenarios involve on-premise systems, this requires a separate configuration in three places:

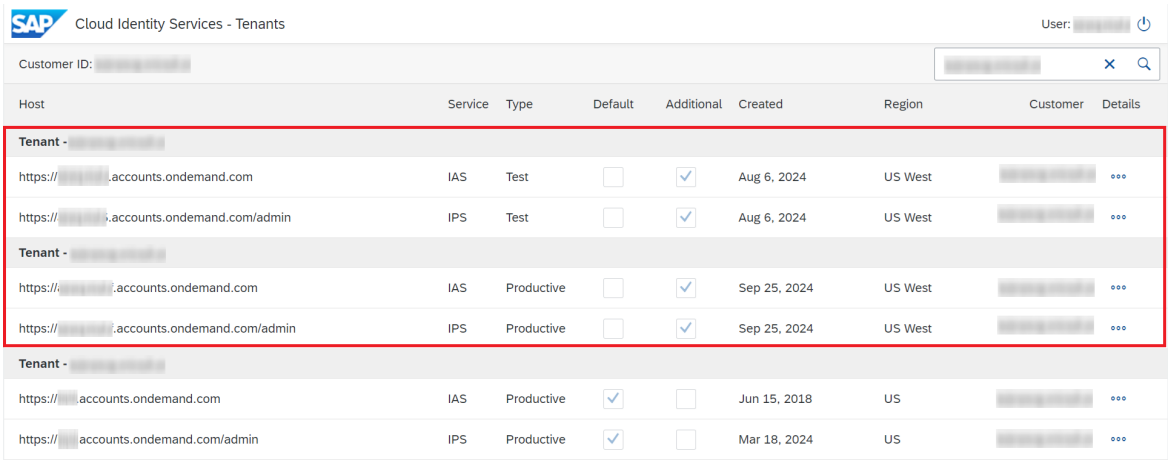
- SAP BTP cockpit, where you subscribe to the Cloud Identity Services connectivity plan in your multi-environment subaccount.
- SAP Cloud Connector, where the connection to your multi-environment subaccount is established, and the backend (on-premise) system is defined.
- The Identity Provisioning section of SAP Cloud Identity Services administration console, where you configure the on-premise provisioning systems.

Procedure

1. Before you start actual configuration, access the *SAP Cloud Identity Services - Tenants* application at the following URL: https://iamtenants.accounts.cloud.sap/ to view the region and the type of Identity Authentication and Identity Provisioning tenants assigned to your customer ID. You will need this information later when creating multi-environment subaccount.

   For more information, see Viewing Assigned Tenants and Administrators.

The screenshot below illustrates a customer landscape with Identity Authentication and Identity Provisioning tenants running on their common SAP Cloud Identity Services infrastructure in one region US West (in the red frame). The first pair is used for testing purposes and the second one for productive purposes.



2. Log on to SAP BTP cockpit and choose your global account.

   If you have only one global account, you are automatically taken there. If you have multiple ones, select the global account you want to set up connection to on-premise system.

   For more information on how to navigate in the SAP BTP cockpit, refer to Navigate in the Cockpit.

3. Create a multi-environment subaccount in the Cloud Foundry region that maps the region of the Identity Authentication tenant (where the Identity Provisioning is also running). See the mapping table below.

Identity Authentication Region	Cloud Foundry Region
Netherlands (Amsterdam) / Germany (Frankfurt)	Europe (Frankfurt) AWS
Germany (Frankfurt)	Europe (Frankfurt) AWS
UAE (Dubai)	Europe (Frankfurt) AWS
Australia (Sydney)	Australia (Sydney) AWS
China (Shanghai)	Singapore AWS
Singapore	Singapore AWS
South Korea (Seoul)	South Korea (Seoul) AWS
Japan (Tokyo) / Japan (Osaka)	Japan (Tokyo) AWS
Brazil (São Paulo)	Brazil (São Paulo) AWS
United States (Sterling) / United States (Colorado)	US East (VA) AWS
Canada (Toronto)	Canada (Montreal) AWS

Identity Authentication Region	Cloud Foundry Region
US West	US West (WA) Azure
Switzerland (Zürich)	Switzerland Azure
India (Mumbai)	India (Mumbai) GCP
Saudi Arabia (Dammam) - Regulated	KSA (Dammam) GCP
Saudi Arabia (Dammam)	Europe (Frankfurt) AWS

For example, customers with Identity Authentication and Identity Provisioning tenants in US West region must create a Cloud Foundry subaccount in US West (WA) Azure region.

Once you create the subaccount, you must enable Cloud Foundry for this subaccount.

> **Note**
>
> If you already have a Cloud Foundry subaccount, you can use it.

4. Open your subaccount, and from the left-side panel choose *Service Marketplace* > *Foundation / Cross Services* > *Cloud Identity Services*.
5. Choose *Create*, select the *connectivity* plan and then *Next*.

   If the connectivity plan is not present, navigate to *Entitlements* > *Configure Entitlements* > *Add Service Plans*. Search for *Cloud Identity Services* > *connectivity plan*, add it as service plan and save your changes.

   > **Note**
   >
   > You can create only one subscription plan per subaccount. This means, you cannot have connectivity along with additional-tenant plan in the same subaccount.

   > **Note**
   >
   > The Cloud Foundry subaccount with the connectivity plan is involved only in setting up the connection, not in transferring data. It is used to establish the tunnel between the SAP Cloud Identity Services tenants (Identity Authentication and Identity Provisioning) and the SAP Cloud Connector. No business data passes through the Cloud Foundry subaccount or its region. It flows directly between the on-premise system and SAP Cloud Identity Services.

6. From the *Cloud Service Type* dropdown, choose for what type of tenant (test or productive) you want to use the subaccount.
   - *Test*
   - *Productive* - default value
7. Choose *Next* and then *Create*.

   This creates a subscription to Cloud Identity Services connectivity plan and creates a binding to your Identity Authentication tenant and your Identity Provisioning service.

> ### Note
>
> You can have two separate SAP BTP multi-environment subaccounts per region: one of them configured for *Productive* connections and the other for *Test* connections. While it is allowed to create multiple Cloud Foundry subaccounts per one region and per one type (test or productive), be aware that in this case only the first one where the connectivity plan was enabled will be used by Identity Provisioning.
>
> The service instance types *Test* and *Productive* map to the tenant types displayed in the *SAP Cloud Identity Services - Tenants* application which is accessible at https://iamtenants.accounts.cloud.sap/.

8. Now, you need to add and connect your subaccounts to the Cloud Connector. Log on to the Cloud Connector administration UI and choose *Add Subaccount*.

   For more information, see Managing Subaccounts.

9. Verify that the Cloud Connector is connected to your Cloud Foundry subaccount. In SAP BTP cockpit, from the left-side panel, choose *Connectivity* > *Cloud Connectors* to see your up and running cloud connector tunnels.
10. Return to the Cloud Connector and define the backend (on-premise) system.
11. Return to your subaccount in SAP BTP cockpit and navigate to *Connectivity* > *Destinations* to configure the destination for your on-premise system.

    > ### Note
    >
    > This step is mandatory only for SAP Application Server ABAP. For the other on-premise systems, you can use the *Properties* tab.

    For more information, see: Create RFC Destinations and SAP Application Server ABAP → step 2.

12. Sign in to SAP Cloud Identity Services administration console.

    The URL follows the pattern: `https://<tenant_id>.accounts.ondemand.com/admin`

13. In the Identity Provisioning section, add an on-premise system (source, target or proxy).
14. If you want to create a connection to SAP AS ABAP, from the *Destination Name* combo box, select the destination you have created in the cockpit and save your configurations.

    If you want to create a connection to other on-premise systems, configure the connection details on the *Properties* tab of the given system.

15. (Optional) If your Cloud Connector is configured with *Location ID*, this location identifier must also be set for the respective on-premise system. You have the following options:

    - Connectivity destination - Create it in your subaccount in the SAP BTP cockpit and provide the Location ID there.

      > ### Note
      >
      > Using connectivity destination is mandatory only for SAP Application Server ABAP.

    - `CloudConnectorLocationId` property - Configure the property in the Identity Provisioning section of SAP Cloud Identity Services administration console for all HTTP and LDAP-based systems, SSH Server (Beta) and SAP HANA Database with ProxyType set to **`OnPremise`**.
      Alternatively, for HTTP-based systems only, you can add the Identity Provisioning `ips.http.header.<header_name>` property, where the header name is: **`SAP-Connectivity-`**

`SCC-Location_ID` and the value is the Location ID. For example: `ips.http.header.SAP-Connectivity-SCC-Location_ID=<LocationID>`

16. Add another provisioning system, connect it to your on-premise one, and run a provisioning job.

1.7.13.14 Start and Stop Provisioning Jobs

You can start and stop a provisioning job from the Identity Provisioning user interface (UI) or from an API client by using the Identity Provisioning tenant admin API.

Prerequisites

- Your source and target systems are configured and enabled.
- (Optional) You have run a *Simulate* and/or a *Validate* job before you run the actual provisioning job to verify that Identity Provisioning configurations produce the desired result in the target systems.

Job Types

The Identity Provisioning service provides the following types of provisioning jobs:

Run From	Job Type	Real Provisioning
Admin console	*Read Job* - Reads all entities from the source system and provisions only new or updated entities to the target system. If the job is run in **delta read** mode, it reads and provisions only new or updated entities in the source system. See Read Provisioning Job [page 2474]	Yes
	Resync Job - Reads all entities from the source system and provisions all entities to the target system. See Resync Provisioning Job [page 2476]	
	Simulate Job - Estimates the number of entities that will be created, updated, deleted or skipped in the target system. Provides the expected results of a resync job without modifying the target system. See Simulate Provisioning Jobs [page 2477]	No
	Validate Job - Verifies how entities (users and groups) would be mapped from source to target systems without modifying them. See Validate Provisioning Jobs [page 2478]	
API client	Use the Identity Provisioning tenant admin API to run a provisioning job from an API client. The API is available on the SAP Business Accelerator Hub. See Run Provisioning Jobs via API [page 2480]	Yes

Start a Job

To run a job, select a source system and choose *Jobs* > `<Job_Type>` > *Run Now*.

Schedule a Job

To schedule a job run, select a source system and choose *Jobs* > *Read Job* > *Schedule*.

Stop a Job

To stop a running job, select a source system and choose the *Stop Job* button in the *Action* column.

1.7.13.14.1 Read Provisioning Job

The *Read* job reads all entities from the source system and provisions only new or updated entities to the target one. If the job is run in **delta read** mode - meaning the `ips.delta.read` property is enabled - it reads and provisions only new or updated entities in the source system.

> **Note**
>
> A Read job checks only for changes in the source system. If there have been changes in the target system, they are not affected by the job.

Although the name of the job implies reading users, a Read job could also lead to deleting users from the target system. This could happen if any of the following changes occur after you have run a provisioning job (Read or Resync):

- A user has been deleted in the source system. As a result, on the next run of the Read job, the deleted user won't be read from the source system and will be deleted in the target system.
- A user filter is applied in the source system. As a result, on the next run of the Read job, the users not matching the filtering criteria will be deleted in the target system.
- A condition is applied either in the source or in the target system. As a result, on the next run of the Read job, the users not matching the condition criteria will be skipped or deleted in the target system.
- The mapping of the targetVariable `entityIdSourceSystem` or `entityIdTargetSystem` has been changed.

> **Example**
>
> You have a source system with users A, B, C and D.

1. Run a Read Job.
   Users A, B, C and D are created in the target system.
2. In the source system, update user C, delete user D and add a new user E.
3. Run a second job.
   - If the second job is a Read Job: It reads users A, B, C and E from the source system and then creates user E, updates user C, and deletes user D in the target system.
   - If the second job is a Delta Read job: It reads users C and E from the source system and then creates user E and updates user C.
   - If the second job is a Resync job: It reads users A, B, C and E from the source system and then creates user E, updates users A, B and C, and deletes user D.

Run Now

To run a read job, select a source system and choose *Jobs* > *Read Job* > *Run Now*. This starts a read job immediately.

Schedule

To schedule a read job, select a source system and choose *Jobs* > *Read Job* > *Schedule*. This runs the job at the scheduled time period.

Option	Description
ON/OFF	Turn the job scheduler on or off: • *ON* - enables the job scheduler. After that, jobs run at the scheduled time period. This option does not run the job immediately. • *OFF* - stops the job scheduler. After that, jobs are stopped from running at the scheduled time. This option does not stop/pause a running job.

Option	Description
Run job every (minutes)	Schedule how often a read job to be run. The number must be larger than **30** (minutes). This option sets the time period but does not run the job immediately. Thus, after you set a scheduled period, turn *ON* the job scheduler. Use cases: • If the scheduled job is finished **before** the next time point, it will start again on the upcoming time point as scheduled, at the precise second. • If the scheduled job is finished **after** the next time point, it will skip the relevant upcoming time point(s) and will start again on the next available one, at the precise second. • If **during** a running scheduled job, you click *Run Now*, this will trigger a manual job, which will start immediately after the current scheduled job has finished. The next scheduled job will start at the upcoming regular time point, at the precise second. → Remember Before you schedule a job, make sure it's not been paused (that is, the job scheduler has not been turned off). Otherwise, the job will not be executed.
Run job on a specific day of the week and time:	Specify the day and time to run the job. You must select at least one day of the week and the exact time. Day and time fields cannot be empty. The job is run in customer's time zone. ⓘ Note This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

1.7.13.14.2 Resync Provisioning Job

The *Resync* job reads all entities from the source system and provisions all entities to the target system.

This job performs a full replace of entities in the target system with entities from the source system. You can use it to fix inconsistent data between both systems. For example, when an entity has been changed or deleted in the target system only.

A Resync job overwrites changes in the target system. As a result, the data between the source and the target system becomes consistent again.

To run a resync job, select a source system and choose *Jobs* > *Resync Job* > *Run Now*. This starts a resync job immediately.

ⓘ Note

Normally, you don't schedule a *Resync Job* as it is expected to be run on demand.

1.7.13.14.3 Simulate Provisioning Jobs

You can simulate a provisioning job before you actually run it.

Prerequisites

The source system where you run the job must be enabled.

Context

Simulating a provisioning job allows you to test your Identity Provisioning configurations and see whether they produce the desired result in the target system. In case the result is not what you have expected, you can identify the wrong configurations and correct them before you run the actual provisioning job.

The simulate job reads the data from the source system, applies the source and target system transformation and provides the expected results of a resync job without actually modifying the target system. The simulation is based on the Identity Provisioning operational data from previously provisioned entities using the same source and target system configurations.

Run this job whenever you change filtering properties, apply conditions or modify attribute mappings in the transformation code of a source and/or target system because these changes affect the data you want to provision. As a result, in the *Job Execution Logs* screen, you will see an estimation of the numbers of users and groups that will be created, updated, deleted or skipped in the target system.

Note that, if some of the entities already exists on the target system, the simulation won't detect them. In such cases during the real provisioning Identity Provisioning will detect them and try to update them, so they may appear as updated entities. The simulation can detect some wrong attribute mappings as missing attributes that are defined as required in the transformation. However, it cannot predict errors that may occur on the target system as duplicate identifiers or not supported values.

Proceed as follows:

Procedure

1. Open the source system and choose the *Jobs* tab.
2. Choose *Run Now* for the *Simulate Job*.
3. Open the *Job Execution Logs* and verify the provisioned entities.

Results

If the number of created, updated, deleted or skipped entities is what you have expected, run the read or resync job.

If the number of created, updated, deleted or skipped entities is not what you have expected, correct your configurations and run the simulate job again.

Related Information

Blog Post: Simulate it until you make it! Try out the Identity Provisioning job that tests your configuration.

1.7.13.14.4 Validate Provisioning Jobs

You can validate a provisioning job before you actually run it.

Prerequisites

- You have enabled the source system where you want to run the validate job from.
- You have created separate CSV input files for validating users and groups.

> **Note**
>
> This functionality is available only for Identity Provisioning tenants running on SAP Cloud Identity infrastructure.

Context

The validate job allows you to test how entities (users and groups) would be mapped from source to target systems before you run the actual provisioning job. You can use it to validate both - default and modified transformations, and see what would be the expected result in the target system.

Like the simulate job, the validate job predicts results in the target system without modifying it. However, unlike the simulate job (which estimates the number of entities that will be created, updated, deleted or skipped), the validate job verifies the content of the entities. For example, you can use it in the following cases:

- You want to run your first provisioning job from system A to system B and see what will be the result when the default transformations are applied.

- You have modified the **`sourcePath`** or the **`targetPath`** attributes in the transformations and you want to see how they will be mapped in the target system. For example, instead of populating the username in SAP Analytics Cloud target system with the email, you want to provision the username itself:

Default Mapping	Changed Mapping

Code Syntax
`{`
`"sourcePath": "$.emails[0].value",`
`"targetPath": "$.userName"`
`},`
	Code Syntax
	`{`
	`"sourcePath": "$.userName",`
	`"targetPath": "$.userName"`
	`},`

- You want to test if conditions are met or if all required user and group attributes are available

To run a validate job, you need to import one or two CSV files - one for users and/or one for groups. Each file must contain a maximum of 10 users or groups with attributes as defined in the source system. The attribute names must use the JSONPath dot-notation. For example: **`emails[0].value`** attribute indicating the value of the first email within an email array, or **`name.familyName`** - a complex **`name`** attribute containing a **`familyName`** sub-attribute. If the file has more than 10 users or groups, the job will validate the first 10 and will ignore the rest.

You can create a CSV file using a text editor, for example Notepad. Make sure the number of fields match the number of headers in the file. Otherwise, you will get an error when importing the file and won't be able to proceed until you correct it.

Example

The following example illustrates that the number of fields does not match the number of headers (columns 1 to 5) at row 3.

```
col1,col2,col3,col4,col5
A,B,,D,E
L,M,N,,
P,Q,
```

Example

The following example illustrates how to validate two users with attributes defined in the MS Entra ID source system.

```
userPrincipalName,id,mail,givenName,surname,groups[0].value,groups[1].value
ChrisEvans,ec2c28da-
a9fe-46c9-876e-564317f9a3af,chris@example.com,Christopher,Evans,Employee,Suppo
rt
MaryWatson,b016ecad-2c30-4fdf-8fb3-117db4911256,mary@example.com,Mary,Watson,E
mployee,Developer
```

For more information on how to create the CSV files and end-to-end examples, see the blog post After simulation, try out validation. Identity Provisioning closes the loop with a fresh new test job.

The validate job is triggered manually. There is no option to schedule it. Proceed as follows:

Procedure

1. Open the source system and choose the *Jobs* tab.
2. For *Validate Job*, choose *Run Now*.
3. In the *Import Entities* dialog box, browse for and select the CSV files for testing users and groups.

   You can import and validate one of the files or both.
4. Choose *Validate*.

Results

The result of a validate job is not displayed in the Job Logs, as it is with the read, resync and simulate jobs. It is provided in a downloadable ZIP file. Each administrator who runs the validate job, can see only his or her test results.

The ZIP file contains one or more CSV files, and a trace.log file in case the validation job identified failed or skipped entities. You can expect the following zipped files: one for each of the entities (users and groups) you have tested, and one for each of the target systems connected to the source system where you run the job from.

For example, if you have tested users and groups from source system A, which is connected to three target systems B, C, and D, expect a ZIP file with six CSV files.

If the result of a validate job is not what you have expected or finished with errors and skipped entities, you can identify where the wrong configurations or missing values come from and correct them.

1.7.13.14.5 Run Provisioning Jobs via API

You can run a provisioning job via API requests.

Prerequisites

You need a technical user with *Access Identity Provisioning Tenant Admin API* permission assigned. For more information, see Managing Administrators.

Context

Use the Identity Provisioning tenant admin API to run a provisioning job from an API client. The API is available on the SAP Business Accelerator Hub: SAP Cloud Identity Services *Identity Provisioning Service* *API Reference* *Jobs*. The URL for accessing the Tenant Admin API follows the pattern: `https://<ias-tenant-host>/ips/service/publicapi/v1/startJob/{SourceSystemId}/jobs/{JobType}`, where:

- `<SourceSystemId>` is the ID of the source system, displayed at the end of the system URL in the SAP Cloud Identity Services administration console.
- `<JobType>` is **READ** or **RESYNC**.

> **Note**
>
> This functionality is available only for Identity Provisioning tenants running on SAP Cloud Identity infrastructure.

1.7.13.15 Handle Rate Limits

Identity Provisioning APIs implement rate limits to control the number of incoming requests for a given time.

If an external system sends requests to Identity Provisioning proxy or real-time APIs and gets the *429* status code *Too Many Requests*, this means that the specified rate limits of the service are exceeded. As a result, Identity Provisioning rejects the requests for a period of time. Rate limits help avoid overloading, misuse of APIs and performance issues.

Identity Provisioning Rate Limits

Value	Description
150	Allowed requests per minute. When the limit is reached, the requests are slowed down.
200	Maximum requests per minute. When the limit is reached, further requests are immediately rejected.

The Identity Provisioning rate limits are enforced at tenant level to the total number of incoming requests (that is, incoming calls for real-time provisioning and proxy systems).

For more information on how Identity Provisioning handles failed operations when the service sends requests to external systems, see Handle Failed Operations [page 2482].

1.7.13.16 Handle Failed Operations

In certain cases, you can set a retry for a failed operation due to an occurred exception.

If an entity operation (*get*, *create*, *update*, or *delete*) fails due to an occurred exception (rate limit, bad gateway, missing authorization, or timeout), you can set it for retry by the Identity Provisioning. You can specify a number of retries by setting the property `ips.failed.request.retry.attempts`. You can also specify a time interval (in seconds) between the retries via the property `ips.failed.request.retry.attempts.interval`. For more information, see List of Properties [page 80].

Based on the system you use, the type of failed operation, and the occurred exception, the option to retry is possible in the following cases:

Identity Provisioning Retry Support

Exception	Write Operation via job or Proxy	Read Operation via job	Read Operation via Proxy
Timeout exception	All connectors	All connectors **Note** The retry is supported only for full read.	The retry is not supported.

Exception	Write Operation via job or Proxy	Read Operation via job	Read Operation via Proxy
Too many requests (429)	• Identity Authentication • Microsoft Entra ID • SAP Analytics Cloud • SAP BTP XS Advanced UAA (Cloud Foundry) • SAP Sales Cloud and SAP Service Cloud • SAP SuccessFactors version 2 • SAP Jam Collaboration • SCIM System • SAP Build Work Zone, advanced edition	• SCIM-based systems (listed in System Types [page 70]) • Microsoft Entra ID **Note** The retry is supported only for full read.	• SCIM-based systems (listed in System Types [page 70]) • Microsoft Entra ID **Note** The retry is supported for single entity read by `ID` and for full read.
Bad gateway (502)	• SAP Build Work Zone, standard edition • SAP BTP XS Advanced UAA (Cloud Foundry) **Note** For SAP Build Work Zone, standard edition and SAP BTP XS Advanced UAA (Cloud Foundry) is supported retry only for patch operation. • SAP Sales Cloud and SAP Service Cloud	SAP Sales Cloud and SAP Service Cloud	SAP Sales Cloud and SAP Service Cloud
Forbidden (403)	SAP Analytics Cloud	The retry is not supported.	The retry is not supported.

1.7.13.17 Reset Identity Provisioning Settings

Resetting your provisioning settings will delete all provisioning systems configured for your tenant, along with the related job execution logs.

Context

Be careful with this option. If you reset your provisioning settings, you will lose all systems, configurations, scheduled jobs, source system subscriptions, and job execution logs. To use the service again afterward, you will need to set up new systems.

If want to reset your provisioning settings, proceed as follows:

Procedure

Sign in to the administration console of SAP Cloud Identity Services, navigate to *Identity Provisioning* and choose *Reset Provisioning Settings*.

Reset Identity Provisioning System [page 2485]

1.7.13.18 Reset Identity Provisioning System

Resetting an Identity Provisioning system (source or target) deletes all Identity Provisioning operational data.

Context

There might be times when you would like to delete the current Identity Provisioning operational data for a particular system. For example, clearing entities that were read from the source system and were then mapped to SCIM specific attributes via the intermediate transformation logic.

This operation is called *system reset*. If you choose it, you only clear the Identity Provisioning operational data. The system configurations and all existing read and provisioned entities, along with their authorizations, will be preserved in the back-end source and target systems. To learn more, see: Transformations [page 388]

Cases that require reset of the provisioning system are:

- Updating the version of the provisioning source or target system; For more information, see Update Connector Version [page 2424].
- Changing the attribute mapped to the variable *entityIdSourceSystem* (for a source system) or *entityIdTargetSystem* (for a target system); For more information, see Transformation Variables [page 490].
- Resetting Identity Authentication target system might be needed after an SAP SuccessFactors instance refresh. For more information, see SAP Note 2954491.

- Database restore of the back-end target system (for example, Identity Authentication). After restoring a previously saved state of the database, some data or configurations might be out of sync. It's recommended that you reset the system before running a provisioning job.

In all other cases, reset is not required, nor recommended. If you have any concerns, report an incident on SAP Support Portal Home for the *BC-IAM-IPS* component.

If you want to reset your system, proceed as follows:

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems* or *Target Systems*
2. Select the relevant source or target system.

   > **Restriction**
   >
   > This *reset* operation is not applicable to proxy systems.

3. At the top right corner of your screen, choose the *Reset* button and confirm the action.

Next Steps

Regardless of the type of system you have reset - source or target ones, continue with the following steps:

1. Start a provisioning job. See: Start and Stop Provisioning Jobs [page 2472]
2. Set the `ips.delete.existedbefore.entities` to **true** on all affected target systems. This ensures that, if from now on you delete entities in the source system, those entities will be recognized as previously existed entities in the target systems and will be deleted there.
3. Start a provisioning job again.

> **Note**
>
> Following a reset, scheduled jobs preserve their defined time period.

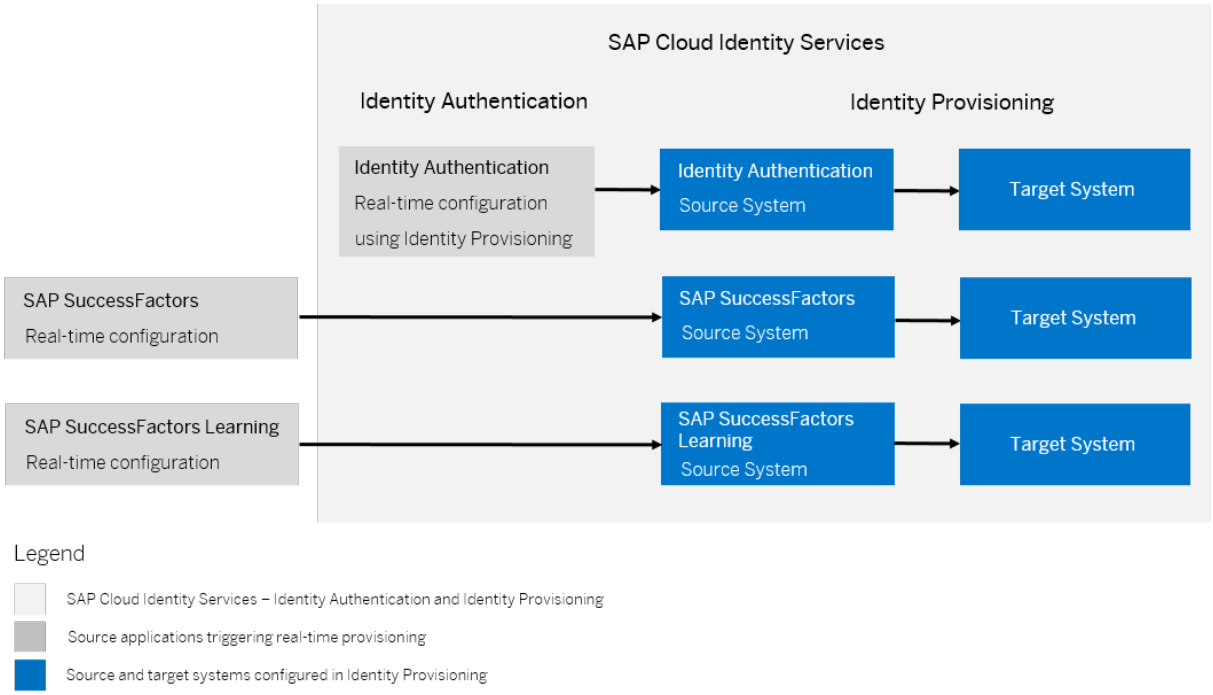
1.7.14 Configuring Real-Time Provisioning

As a tenant administrator, you can configure real-time provisioning to immediately provision entities from source to target systems.

This feature allows you to synchronize newly created, updated or deleted users and groups without the need to run manual or scheduled jobs in Identity Provisioning. It is useful in scenarios where synchronous provisioning is required, such as: user self-registration that needs immediate system access.

The real-time provisioning process involves the following set-ups. First, you need a source application which triggers the real-time sync when changes occur. Second, you must configure the source application as a source system in the Identity Provisioning. Finally, you need to add one or more target systems in the Identity Provisioning, where the real-time changes will be synchronized and reflected immediately.

The following diagram illustrates the process.



For more information on how to enable real-time sync in SAP SuccessFactors, see Managing Identity Authentication/Identity Provisioning Real Time Sync.

For more information on the real-time sync configuration in SAP SuccessFactors Learning, see Learning Configuration Procedure.

Changes related to users in Identity Authentication can also be provisioned real-time directly to SAP Jam without using Identity Provisioning. For more information, see Configure SAP Jam for Real-Time Provisioning [page 2492].

Standard vs Real-Time

Provisioning Mode	Use Case	Key Differences	Source Systems
Standard	Use it for initial, regular and scheduled *Read* and *Resync* provisioning jobs of users and groups from any supported source system to any target system.	• Starting a provisioning job in Identity Provisioning is required. • Users and groups (roles) are provisioned. • Filtering properties are considered.	**All source systems** (supported by Identity Provisioning)

Provisioning Mode	Use Case	Key Differences	Source Systems
Real-Time	Use it for instant provisioning of a single or a number of users or groups that were newly created or updated in the supported source system to any target system.	• You don't start a provisioning job. Changes in the user account (create, update, delete) trigger real-time sync. • Users and groups are provisioned real time. **Note** Real-time provisioning of groups can be configured for each source system that supports the execution of requests to the `/Groups` endpoint of the Real-time provisioning API. • Filtering properties are not considered.	• Identity Authentication • SAP SuccessFactors • SAP SuccessFactors Learning

Real-Time Workflow

Configuring real-time provisioning involves the following steps:

1. Create a technical user for accessing the real-time provisioning API and assign it the *Access Real-Time Provisioning API* permission. This user must be an administrator of type *System*.
   For more information, see Add System as Administrator [page 2305].
2. Configure the application which triggers real-time provisioning as a source system in Identity Provisioning, for example SAP SuccessFactors.
   For more information, see Source Systems [page 585].
3. Connect this source system to one or more target systems, for example Identity Authentication.
   For more information, see Target Systems [page 936] and Provision Users to Target Systems [page 2498].
4. Enable the real-time provisioning configuration in the source application that triggers it, for example SAP SuccessFactors.
   For more information, see Enable Real-Time Provisioning in Source Applications [page 2491].
5. Create or update a user in the source application. For example, create a user with *Onboardee* user account type in SAP SuccessFactors.
   As a result, the onboardee user will be immediately provisioned to Identity Authentication.
   When the source and target systems are configured for real-time provisioning scenarios, the following behavior can be expected:
   - **If a condition is applied in the source transformation:** Entities that do not meet the filtering criteria will either be deprovisioned or not updated in the target system.

- **If a condition is applied in the target transformation:** Entities that do not meet the filtering criteria will either be deprovisioned or skipped in the target system.

1.7.14.1 Enable Real-Time Provisioning in Source Applications

Enable the real-time provisioning configuration in the source applications that trigger immediate sync when changes occur.

> ⓘ Note
>
> In the context of real-time provisioning, Identity Authentication, SAP SuccessFactors and SAP SuccessFactors Learning are considered source applications.

The way you enable real-time provisioning differs among applications. SAP SuccessFactors requires that you turn on the Enable Real Time Sync option in the Admin Center. Identity Authentication requires that you configure Identity Provisioning as a target system in the SAP Cloud Identity Services admin console.

Regardless of application-specific configurations, you are always required to provide the real-time provisioning endpoint URL, the authentication type and credentials.

Identity Authentication

- Configure Identity Authentication for Real-Time Provisioning [page 2493]

SAP SuccessFactors

- Manage Real-Time Sync of New Hires from SAP SuccessFactors to Identity Authentication with Identity Provisioning
- Managing Identity Authentication/Identity Provisioning Real Time Sync

SAP SuccessFactors Learning

- Learning Configuration Procedure

  > ⚠ Restriction
  >
  > Real-time provisioning of **groups** is not supported for this system.

Delete Target System [page 2503]

1.7.14.2 Configure SAP Jam for Real-Time Provisioning

Tenant administrators can configure SAP Jam target systems for real-time provisioning via the administration console for SAP Cloud Identity Services.

Prerequisites

You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

> ⓘ Note
>
> Currently, Identity Authentication supports real-time provisioning to SAP Jam and SAP Cloud Identity Services - Identity Provisioning instances.

> → Remember
>
> Use the Identity Authentication real-time provisioning feature for up to 500 users.
>
> If you want to provision more than 500 user, use Identity Provisioning. For more information, see Configure Identity Authentication for Real-Time Provisioning [page 2493]. The content in this section is not relevant for China (Shanghai) region.

Context

To configure an SAP Jam target system, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Real-Time Provisioning* tile.

   This operation opens a list of the target systems.
3. Press the *+Add* button on the left-hand panel to add a new target system to the list.
4. Make the corresponding entries in the *Target Configurations* and *Authentication Configurations* fields for the target system you want to add.

   All fields are obligatory.

   > → Remember
   >
   > Choose *SAP Jam* from the drop-down.

5. Save your changes.

   If the operation is successful, the system displays the message `System <name of system> configuration updated.`
6. (Optional) To check the SAP Jam Target System configuration press the *Test Connection* button.

   If the operation is successful, the system displays the message `Connection to the selected target system was established successfully.`

   > **Note**
   >
   > To change the configuration, select the target system, press *Edit*, fill in the fields with the new entries, and save your changes.

Next Steps

Provision Users to Target Systems [page 2498]

Task overview: Configuring Real-Time Provisioning [page 2487]

Related Information

Delete Target System [page 2503]
Configuring Real-Time Provisioning [page 2487]

1.7.14.3 Configure Identity Authentication for Real-Time Provisioning

Enable real-time provisioning in Identity Authentication to trigger immediate synchronization of user changes to target systems configured in Identity Provisioning.

Prerequisites

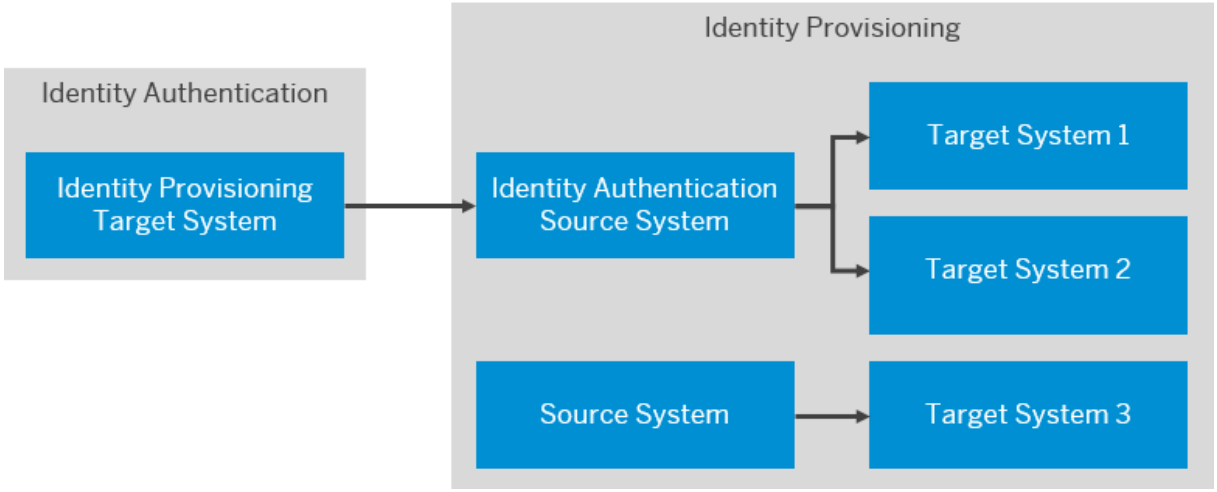
- You have created a technical user for accessing the real-time provisioning API and assigned it the *Access Real-Time Provisioning API* permission. This user must be an administrator of type *System*. You have also configured *Secret* for the technical user.
  For more information, see Add System as Administrator [page 2305].

For OAuth authentication scenario for tenants running on Neo environment, you've made the required configurations in the SAP BTP cockpit. For more information, see Create OAuth Client Credentials in SAP BTP Cockpit.

- You have created Identity Authentication source system in Identity Provisioning and connected it to target systems of your choice.
  For more information, see Identity Authentication [page 586] and Target Systems [page 936].

Context

In this scenario you configure Identity Provisioning as a target system in Identity Authentication real-time configuration, and Identity Authentication as a source system in Identity Provisioning. As a result, when users are created, updated or deleted in Identity Authentication, the changes will be immediately provisioned to the target systems configured in Identity Provisioning.



Real-time provisioning is applicable for users that have been manually created or updated in Identity Authentication, using SCIM API (version 1 or 2), or via CSV file upload. It is not applicable for users updated by a provisioning job.

> ⚠ Caution
>
> Users coming from a source (system A) which are created or updated in Identity Authentication target (system B) using a provisioning job, **cannot** be later synchronized from Identity Authentication to another target (system C) using real-time provisioning. This is a precaution behavior, preventing any data collisions if you later decide to run a provisioning job for the same systems: Identity Authentication source (system B) and target (system C). See the example below.

> ✤ Example
>
> 1. You enable real-time provisioning for Identity Authentication and configure it as a source system that points to SAP Marketing Cloud target system.
>   As a result, Identity Authentication users are immediately provisioned to SAP Marketing Cloud.
> 2. You configure Microsoft Active Directory as a source system that points to Identity Authentication target system and run a provisioning job.

As a result, Microsoft Active Directory users are provisioned to Identity Authentication. Even though new users are created in Identity Authentication, they are not provisioned further to SAP Marketing Cloud by real-time provisioning.

→ Tip

If you want to provision groups in real time, you need to use a REST client for initiating POST and DELETE requests to the Real-time provisioning API: `https://<tenantId>.<host>/ipsproxy/service/api/v1/systems/<system-id>/entities/group`.

To configure real-time provisioning in Identity Authentication to trigger immediate synchronization of user changes to target systems configured in Identity Provisioning follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Real-Time Provisioning* tile.

   This operation opens a list of the target systems.
3. Choose the *+Add* button to add a new target system and provide the following information:

New System	Field	Value
Target Configurations	*Display Name*	Provide a name for the target system. It can be identical with the source system you have created in Identity Provisioning.
	Type	From the dropdown, select *Identity Provisioning*.
	SCIM URL	Provide the SCIM URL in the following pattern: `https://<ias-tenant-host>/ipsproxy/service/api/v1/systems/<system-id>/entities/user` The `<system-id>` is the ID of the *Identity Authentication* source system you have added in Identity Provisioning. It is displayed at the end of the system URL.

New System	Field	Value
	Version • *1* • *2*	Defines the version of Identity Authentication SCIM API. *1* - the Identity Authentication SCIM API (in short, SCIM API version 1) is used. *2* - the Identity Directory SCIM API (in short, SCIM API version 2) is used. **Note** The version that you specify here must be the same as the version of the `ias.api.version` property in Identity Authentication source system.
Authentication Mechanism	*OAuth*	For tenants running on SAP Cloud Identity infrastructure, use the **user ID** and **password** of the Identity Authentication technical user. Provide an OAuth token URL following the pattern: `https://<ias-tenant-host>/oauth2/token` **Note** OAuth authentication is only supported when calling the Real-Time Provisioning API. It cannot be configured in the administration console of SAP Cloud Identity Services. For more information for tenants running on Neo environment, see Create OAuth Client Credentials in SAP BTP Cockpit.

New System	Field	Value
	Basic	If you choose this option, provide the following information: In the *Username* field, enter the client ID of the technical user. In the *Password* field, enter the client secret of the technical user. For more information, see *step 6* in Add System as Administrator.
	Certificate	If you choose this option, proceed as follows: 1. Provide a common name and a password. 2. Generate and download the certificate. 3. Import it in the *Configure System Authentication* screen of the technical user for real-time provisioning, as described in *step 6* in Add System as Administrator. The maximum length of the CN is 64 characters. Once the certificate is generated, it is saved as a `.crt` file. The common name is in the format `<common name>(<admin user ID>)`, where common name is the CN provided by the administrator, and admin user ID is the administrator's user id. Identity Authentication supports SAP Passport CA as trusted certificate authority (CA).

4. Save your changes.

   If the operation is successful, the system displays the message: `Target system <name of system> created`.

5. **Optional:** Choose *Test Connection* before executing the provisioning.

   If the setup is correct, the following message is displayed: `Connection to the selected target system was established successfully.`

6. Choose *Provision*.

Next Steps

Verify that the changes in Identity Authentication are provisioned to the target systems configured in Identity Provisioning. Each subsequently created or updated users will be provisioned instantly and automatically.

Task overview: Configuring Real-Time Provisioning [page 2487]

Related Information

Delete Target System [page 2503]

1.7.14.4 Provision Users to Target Systems

Tenant administrators can provision users of Identity Authentication to SAP Jam and Identity Provisioning target systems.

Prerequisites

- You are assigned the *Manage Users* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured a target system in the administration console for SAP Cloud Identity Services. For more details about how to configure target systems, see Configure SAP Jam for Real-Time Provisioning [page 2492] or Configure Identity Authentication for Real-Time Provisioning [page 2493].

> ⓘ Note
>
> Currently, Identity Authentication supports real-time provisioning to instances of:
>
> - SAP Jam
>
>   > → Remember
>   >
>   > Use the Identity Authentication real-time provisioning feature for provisioning of up to 500 users. If you want to provision more than 500 user, use Identity Provisioning. For more information, see SAP Cloud Identity Services - Identity Provisioning
>
> - SAP Cloud Identity Services - Identity Provisioning

Context

Identity Authentication supports the following scenarios for real-time provisioning to target systems:

- Provision all users to selected target systems - In this scenario, all users in the user store of Identity Authentication are provisioned to a specific target system. The tenant administrator chooses the target system that all users will be provisioned to.
- Provision selected users to all target systems - In this scenario, the tenant administrator provisions particular users to all target systems that are configured. The administrator chooses which users to provision.
- Provision users from corporate user store - In this scenario, the users who are stored in a corporate user store are provisioned during authentication.
- Provision users at user creation and update - In this scenario, all newly created or updated the users are automatically provisioned to all target systems.

→ Remember

The users that are in the user store of Identity Authentication are provisioned to the SAP Jam target system with a certain set of attributes. The table below shows the attributes taken from Identity Authentication and their mapping to the SAP Jam target system.

Attribute Mapping Between Identity Authentication and SAP Jam

Identity Authentication Attribute	SAP Jam Attribute
Core Schema	
firstName	name.givenName
lastName	name.familyName
uid	userName
title	jobFunction
userType	type
mail	emails.value
status	active **Note** `active` is *true* only when `status` in Identity Authentication is equal to `active`. In the other case `active` is false.
telephone	phoneNumbers[work].value
street	addresses[home].streetAddress
city	addresses[home].locality

Identity Authentication Attribute	SAP Jam Attribute
zip	addresses[home].postalCode
country	addresses[home].country
companyStreet	addresses[work].streetAddress
companyCity	addresses[work].locality
companyZip	addresses[work].postalCode
companyCountry	addresses[work].country
locale	locale **Note** The locale must be of the format ll_CC where: • `ll` is the language two letter code in small letters • `CC` is the country (region) two letter code in capital letters **Caution** Do not send `locale` if `language` or `country` user attribute is missing.
Enterprise User Schema Extension	
employeeNumber	personnelNumber
costCenter	costCenter
organization	company
division	division
department	department

Note

If Identity Authentication is used as proxy to delegate the authentication to a corporate identity provider, the users that are authenticated by the corporate identity provider will not be provisioned during authentication.

When you delete a user, he or she is automatically deprovisioned from the configured target systems.

To provision users, choose one of the options below and follow the corresponding procedure.

Task overview: Configuring Real-Time Provisioning [page 2487]

Related Information

Enable Real-Time Provisioning in Source Applications [page 2491]

Delete Target System [page 2503]

Provision All Users to a Selected Target System

Context

The tenant administrator can select the target systems that all users will be provisioned to.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Real-Time Provisioning* tile.

   This operation opens a list of the target systems.
3. Choose the list item of the target system that you want to provision the users to.

   > ⓘ Note
   >
   > If you do not have a configured target system in your list, you can add one. For more details, see Configure SAP Jam for Real-Time Provisioning [page 2492].

   > ⓘ Note
   >
   > The configuration of OAuth authentication mechanism via the administration console of SAP Cloud Identity Services is not supported.
4. Press *Provision*.

   If the operation is successful, the system displays the message `<number of users> provisioned`.

Provision Selected Users to All Target Systems

Context

The tenant administrator can choose which of the users to be provisioned to the configured target systems.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *User Management* tile.

   The system displays the first 20 users in the tenant sorted by their user ID number.
3. **Optional:** You can choose one of the following:

   Search Options

List All Users Press *More*	This will expand the list by 20 users. **Note** This option is available only if there are more than 20 users in the tenant.
Unfiltered Search • (default mode) Type your search criteria string in the search field and press the *Enter* key • (when in *Filtered Search* mode) Press *Hide Filters*, type your search criteria string in the search field, and press the *Enter* key	Once the search is completed, the system will list the users whose *User ID*, *Global User ID*, *SCIM ID*, *Email*, or *Login Name* match your search criteria string. In this case the system doesn't include the *First Name* and *Last Name* fields in the search. If you aren't satisfied with the search result, edit your search criteria and repeat the step again.
Filtered Search Press *Show Filters*, type your search criteria strings in at least one of the search fields, and press the *Enter* key	The system checks the search fields simultaneously. Once the search is completed, it will list the users that match the search criteria from all the fields.

4. Select the checkbox next to the user or users that you want to provision.
5. Press *Provision Users*.
6. Confirm the operation.

   If the operation is successful, the system displays the message `<number of users> provisioned`.

Provision Users from Corporate User Store

> **Note**
>
> The content in this section is only relevant for SAP BTP, Neo environment.

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

A user is automatically provisioned after he or she has been authenticated.

For more information about how to configure Identity Authentication to use a corporate user store in addition to its own user store, see Configure Connection to a Corporate User Store [page 2535].

Provision Users at User Create and User Update

All newly created and updated users are automatically provisioned to the target systems configured in the administration console for SAP Cloud Identity Services. The users that use the self-registration service will be automatically provisioned to the target systems too.

For more information about user creation or user update, see **Related Information**

Delete Multiple Target Systems

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Real-Time Provisioning* tile.

   This operation opens a list of the target systems.
3. Choose the icon in the left-hand panel.

   This operation activates the *Delete Target Systems* mode.
4. Select the target system or systems that you want to delete.
5. Choose the *Delete* button.
6. Confirm the operation in the pop-up dialog.

   Once the target system or systems have been deleted, the system displays the message `<number> target systems deleted`.

Delete Single Target System

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Users & Authorizations*, choose the *Real-Time Provisioning* tile.

   This operation opens a list of the target systems.
3. Select the target system that you want to delete.
4. Choose the *Delete* button in the right-hand panel to delete the selected target system.
5. Confirm the operation in the pop-up dialog.

   Once the application has been deleted, the system displays the message `1 target system deleted`.

1.7.15 Configuring Social Identity Providers

By configuring a social provider, users can log on to applications with their social media credentials by linking their accounts in Identity Authentication to the social media account.

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via one of the following predefined social providers:

- Apple ID
- Google
- Facebook
- LinkedIn
- X

Once a user has allowed Identity Authentication to link his or her account with the social provider accounts, the user can log on to applications via these social providers.

Configure Google as Identity Provider [page 2506]
: By configuring Google as a social identity provider, users can log on to applications with their Google credentials by liking their accounts in Identity Authentication to the Google account.

1.7.15.1 Configure Google as Identity Provider

By configuring Google as a social identity provider, users can log on to applications with their Google credentials by liking their accounts in Identity Authentication to the Google account.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via Google as a social identity provider.

Once a user has allowed Identity Authentication to link his or her account with the Google account, the user can log on to applications via the social provider.

To configure Google as social identity provider for the tenant, you have to register new applications on the Google site. For more details, see Verify your site ownership .

> **Note**
>
> You need to type **`https://<tenant ID>.accounts.ondemand.com/ui/oauth/googleCallback`** in the *Authorized redirect URIs* field when you create your client ID in Google Developers Console. For more information about the redirect URIs for your OAuth 2.0 credentials, see Set a redirect URI .

To perform the social identity provider configuration in the administration console for SAP Cloud Identity Services, you have to provide the following data:

Required Google Settings

Authentication Attribute	Description
Google's client ID	The Google OAuth 2.0 credential after you set a project in the Google Developers Console.
Google's client secret	The Google OAuth 2.0 credential after you set a project in the Google Developers Console.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of the social providers.
3. Choose the Google list item.
4. Under *Configuration*, choose *Edit*.
5. Enter the generated authentication attributes from the social provider.

Option	Description
Client ID	The Google OAuth 2.0 credential after you set a project in the Google Developers Console.
Client Secret	The Google OAuth 2.0 credential after you set a project in the Google Developers Console.

   > ### Note
   >
   > Check for leading or trailing spaces in the authentication attributes fields, and delete them. Sign-on through the social identity provider will not work if there are blank spaces before or after the strings in the fields.

6. Save your configuration.

   If the operation is successful, you will receive the following message: `Google authentication configured`. The slider next to the social provider is switched to *ON*.

   > ### Note
   >
   > With the slider *ON* the social identity provider is shown as authentication option on the logon screen. If you do not want to show any of the social providers on the logon screen, you can drag the slider next to the social provider to *OFF*. The configuration for this social provider will be preserved, but the social provider will not appear on the logon pages of the applications in the tenant.
   >
   > To disable the social sign option for a specific social provider, remove the configuration for that provider. See Related Information for more details.

Next Steps

The above configurations are valid for the whole tenant. They will take effect for a specific application if you enable the *Social Sign-On* option via the administration console. For more information about how to enable social sign on for a specific application, see Enable or Disable Social Sign-On for an Application [page 2020].

1.7.15.2 Configure Facebook as Identity Provider

By configuring Facebook as a social identity provider, users can log on to applications with their social media credentials by liking their accounts in Identity Authentication to the social media account.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via Facebook as a social identity provider.

Once a user has allowed Identity Authentication to link his or her account with the Facebook account, the user can log on to applications via the social provider.

To configure Facebook as social identity provider for the tenant, you have to register new applications on the Facebook site. For more details, see Related Information.

> **Note**
>
> You need to type **`https://<tenant ID>.accounts.ondemand.com/ui/oauth/oauthCallback`** in the *Valid OAuth redirect URIs* field in the Settings section of Facebook Login in the App Dashboard. For more information about Facebook Valid OAuth redirect URIs, see Enable Strict Mode .

To perform the social identity provider configuration in the administration console for SAP Cloud Identity Services, you have to provide the following data:

Required Facebook Settings

Authentication Attribute	Description
Facebook's application ID	The ID generated after you add an application on Facebook.
Facebook's application secret	The secret generated after you add an application on Facebook.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of the social providers.
3. Choose the Facebook list item.
4. Under *Configuration*, choose *Edit*.
5. Enter the generated authentication attributes from the social provider.

   > ### Note
   >
   > Check for leading or trailing spaces in the authentication attributes fields, and delete them. Sign-on through the social identity provider will not work if there are blank spaces before or after the strings in the fields.
6. Save your configuration.

   If the operation is successful, you will receive the following message: `Facebook authentication configured`. The slider next to the social provider is switched to *ON*.

   > ### Note
   >
   > With the slider *ON* the social identity provider is shown as authentication option on the logon screen. If you do not want to show any of the social providers on the logon screen, you can drag the slider next to the social provider to *OFF*. The configuration for this social provider will be preserved, but the social provider will not appear on the logon pages of the applications in the tenant.
   >
   > To disable the social sign option for a specific social provider, remove the configuration for that provider. See Related Information for more details.

Next Steps

The above configurations are valid for the whole tenant. They will take effect for a specific application if you enable the *Social Sign-On* option via the administration console. For more information about how to enable social sign on for a specific application, see Enable or Disable Social Sign-On for an Application [page 2020].

1.7.15.3 Configure LinkedIn as Identity Provider

By configuring LinkedIn as social identity provider, users can log on to applications with their LinkedIn credentials by linking their accounts in Identity Authentication to the LinkedIn account.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via LinkedIn as a social identity provider.

Once a user has allowed Identity Authentication to link his or her account with the LinkedIn account, the user can log on to applications via the social provider.

To configure LinkedIn as social identity provider for the tenant, you have to register new applications on the LinkedIn site.

> **Note**
>
> You need to type **`https://<tenant ID>.accounts.ondemand.com/ui/oauth/oauthCallback`** in the *Redirect URLs* field in the *Auth* tab in the LinkedIn Developer Platform. For more information about the redirect URLs for your OAuth 2.0 credentials, see Step 1: Configure Your Application .

To perform the social identity provider configuration in the administration console for SAP Cloud Identity Services, you have to provide the following data:

Required LinkedIn Settings

Authentication Attribute	Description
LinkedIn's Client ID (API key)	The key generated by LinkedIn to identify a user application and for API calls.
LinkedIn's Client Secret (API secret)	The secret generated by LinkedIn to identify a user application and for API calls.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of the social providers.
3. Choose the LinkedIn list item.
4. Under *Configuration*, choose *Edit*.
5. Enter the generated authentication attributes from the social provider.

   > ### Note
   >
   > Check for leading or trailing spaces in the authentication attributes fields, and delete them. Sign-on through the social identity provider will not work if there are blank spaces before or after the strings in the fields.
6. Save your configuration.

   If the operation is successful, you will receive the following message: `LinkedIn authentication configured`. The slider next to the social provider is switched to *ON*.

   > ### Note
   >
   > With the slider *ON* the social identity provider is shown as authentication option on the logon screen. If you do not want to show any of the social providers on the logon screen, you can drag the slider next to the social provider to *OFF*. The configuration for this social provider will be preserved, but the social provider will not appear on the logon pages of the applications in the tenant.
   >
   > To disable the social sign option for a specific social provider, remove the configuration for that provider. See Related Information for more details.

Next Steps

The above configurations are valid for the whole tenant. They will take effect for a specific application if you enable the *Social Sign-On* option via the administration console. For more information about how to enable social sign on for a specific application, see Enable or Disable Social Sign-On for an Application [page 2020].

1.7.15.4 Configure X as Identity Provider

By configuring X as social provider, users can log on to applications with their X credentials by liking their accounts in Identity Authentication to the X account.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via X as a social identity provider.

Once a user has allowed Identity Authentication to link his or her account with the X account, the user can log on to applications via the social provider.

To configure X as social identity provider for the tenant, you have to register new applications on the X site. For more details, see Create a Project and connect an App .

> **Note**
>
> You need to type **`https://<tenant ID>.accounts.ondemand.com/ui/oauth/oauthCallback`** in the *Callback URLs* field in the Create an application section of X Application Management page. For more information about X Callback URL, see Callback URL .

To perform the social identity provider configuration in the administration console for SAP Cloud Identity Services, you have to provide the following data:

Required X Settings

Authentication Attribute	Description
X consumer key	The key generated by X to identify which user application is making the request.
X consumer secret	The secret generated by X to identify which user application is making the request.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of the social providers.
3. Choose the X list item.
4. Under *Configuration*, choose *Edit*.
5. Enter the generated authentication attributes from the social provider.

   > **Note**
   >
   > Check for leading or trailing spaces in the authentication attributes fields, and delete them. Sign-on through the social identity provider will not work if there are blank spaces before or after the strings in the fields.
6. Save your configuration.

   If the operation is successful, you will receive the following message: `X authentication configured`. The slider next to the social provider is switched to *ON*.

   > **Note**
   >
   > With the slider *ON* the social identity provider is shown as authentication option on the logon screen. If you do not want to show any of the social providers on the logon screen, you can drag the slider next to the social provider to *OFF*. The configuration for this social provider will be preserved, but the social provider will not appear on the logon pages of the applications in the tenant.
   >
   > To disable the social sign option for a specific social provider, remove the configuration for that provider. See Related Information for more details.

Next Steps

The above configurations are valid for the whole tenant. They will take effect for a specific application if you enable the *Social Sign-On* option via the administration console. For more information about how to enable social sign on for a specific application, see Enable or Disable Social Sign-On for an Application [page 2020].

1.7.15.5 Configure Apple as Identity Provider

Users can log on to applications with their Apple ID credentials by linking their accounts in Identity Authentication to their Apple account.

Prerequisites

You have a developer account at Apple.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Identity Authentication uses the OAuth protocol for social sign-on via Apple as a social identity provider.

Once a user has allowed Identity Authentication to link his or her account with the Apple ID account, the user can log on to applications via the social provider.

To configure sign in with Apple for the tenant, first you have to register an Application ID (App ID) and Services ID. For more details, see Configure Sign in with Apple for the web .

> **Note**
>
> You must type **`https://<tenant ID>.accounts.ondemand.com`** in the *Domains and Subdomains* box, and **`https://<tenant ID>.accounts.ondemand.com/ui/oauth/oauthCallback`** in the *Return URLs* box when you enable and configure the *Sign in with Apple* option at the Apple Developer site.

To perform the social identity provider configuration in the administration console for SAP Cloud Identity Services, you have to provide the following data:

Required Apple Settings

Authentication Attribute	Description
Client ID	The *Services ID* that you registered at Apple site.
Team ID	A 10-digit key generated by Apple. You can see your Team ID under the membership information at Apple site.
Key ID	For the Key ID, you must register a key at the apple site. → Remember You must provide a name for your key and select the *Sign in with Apple* check box. Once you configure your key, it needs to be bound to your primary App ID.
Client Certificate	The private key provided by Apple in a `.p8` file. To use the key for the configuration in the administration console for SAP Cloud Identity Services, copy and paste the text from the `.p8` file.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of social providers.
3. Choose the *Apple* list item.
4. Under *Configuration*, choose *Edit*.
5. Enter the generated authentication attributes from Apple.

   > **Note**
   >
   > Check for leading or trailing spaces in the authentication attributes fields, and delete them. Sign-on through the social identity provider will work if there are blank spaces before or after the strings in the fields.

6. Save your configuration.

   If the operation is successful, you receive the following message: `Apple authentication configured`. The slider next to the social provider is switched to *ON*.

   > **Note**
   >
   > With the slider *ON* the social identity provider is shown as authentication option on the logon screen. If you do not want to show any of the social providers on the logon screen, you can drag the slider next to the social provider to *OFF*. The configuration for this social provider will be preserved, but the social provider will not appear on the logon pages of the applications in the tenant.
   >
   > To disable the social sign option for a specific social provider, remove the configuration for that provider. See Related Information for more details.

Next Steps

The above configurations are valid for the whole tenant. They will take effect for a specific application if you enable the *Social Sign-On* option via the administration console. For more information about how to enable social sign-on for a specific application, see Enable or Disable Social Sign-On for an Application [page 2020].

1.7.15.6 Remove Social Identity Providers Configuration

You can remove the configurations of the social providers in the administration console for SAP Cloud Identity Services.

Prerequisites

You have a configured social provider in the administration console.

Context

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Social Identity Providers* tile.

   This operation opens a list of the social providers.
3. Choose the list item of the social provider whose configuration you want to remove.
4. Choose *<Social Provider Name> Sign-On*.
5. Choose the *Remove Configuration* button.
6. Confirm your choice.

Results

The configuration for the selected social provider will be removed. The social provider will not appear on the logon pages of the applications in the tenant.

1.7.16 Integrating with Existing Customer Landscape

Identity Authentication can be integrated with already existing customer landscape and supports different types of delegated authentication.

The table shows the available options and what are the suitable use-cases:

Use Case	Configuration
Corporate User Store	• Corporate User Store (Cloud Foundry Environment) [page 2519] • Corporate User Store (Neo Environment) [page 2531]
Kerberos Authentication	• Configure Kerberos Authentication [page 2548] • Enable or Disable Kerberos Authentication for an Application [page 2556]
Identity Provider Proxy	Corporate Identity Providers [page 2556]

1.7.16.1 Corporate User Store

If you have an existing on-premise user store, you can configure Identity Authentication to use the corporate user store in addition to its own cloud user store.

The integration between Identity Authentication and the corporate user store allows users to authenticate with their corporate credentials from the corporate user store, without the need to use another set of credentials for their cloud access.

You can have two configurations, depending on the SAP BTP environment, you are using:

- Corporate User Store (Cloud Foundry Environment) [page 2519]
  Recommended.
- Corporate User Store (Neo Environment) [page 2531]
  Recommended if you are using SAP NetWeaver AS JAVA, with the following variants:
  - SAP NetWeaver AS JAVA - UME
  - SAP NetWeaver AS JAVA - UME
  - Multiple Active Directories connected to SAP NetWeaver AS JAVA - UME
  - SAP NetWeaver AS ABAP connected to SAP NetWeaver AS JAVA - UME

1.7.16.1.1 Corporate User Store (Cloud Foundry Environment)

Configure corporate user store for applications in the Cloud Foundry environment to allow users to authenticate with their corporate credentials, without the need to use another set of credentials for their cloud access.

> ⓘ Note
>
> The content in this section is only relevant for SAP BTP, Cloud Foundry environment.

> → Tip
>
> The Cloud Foundry setup can be used also for applications that are in the Neo environment.

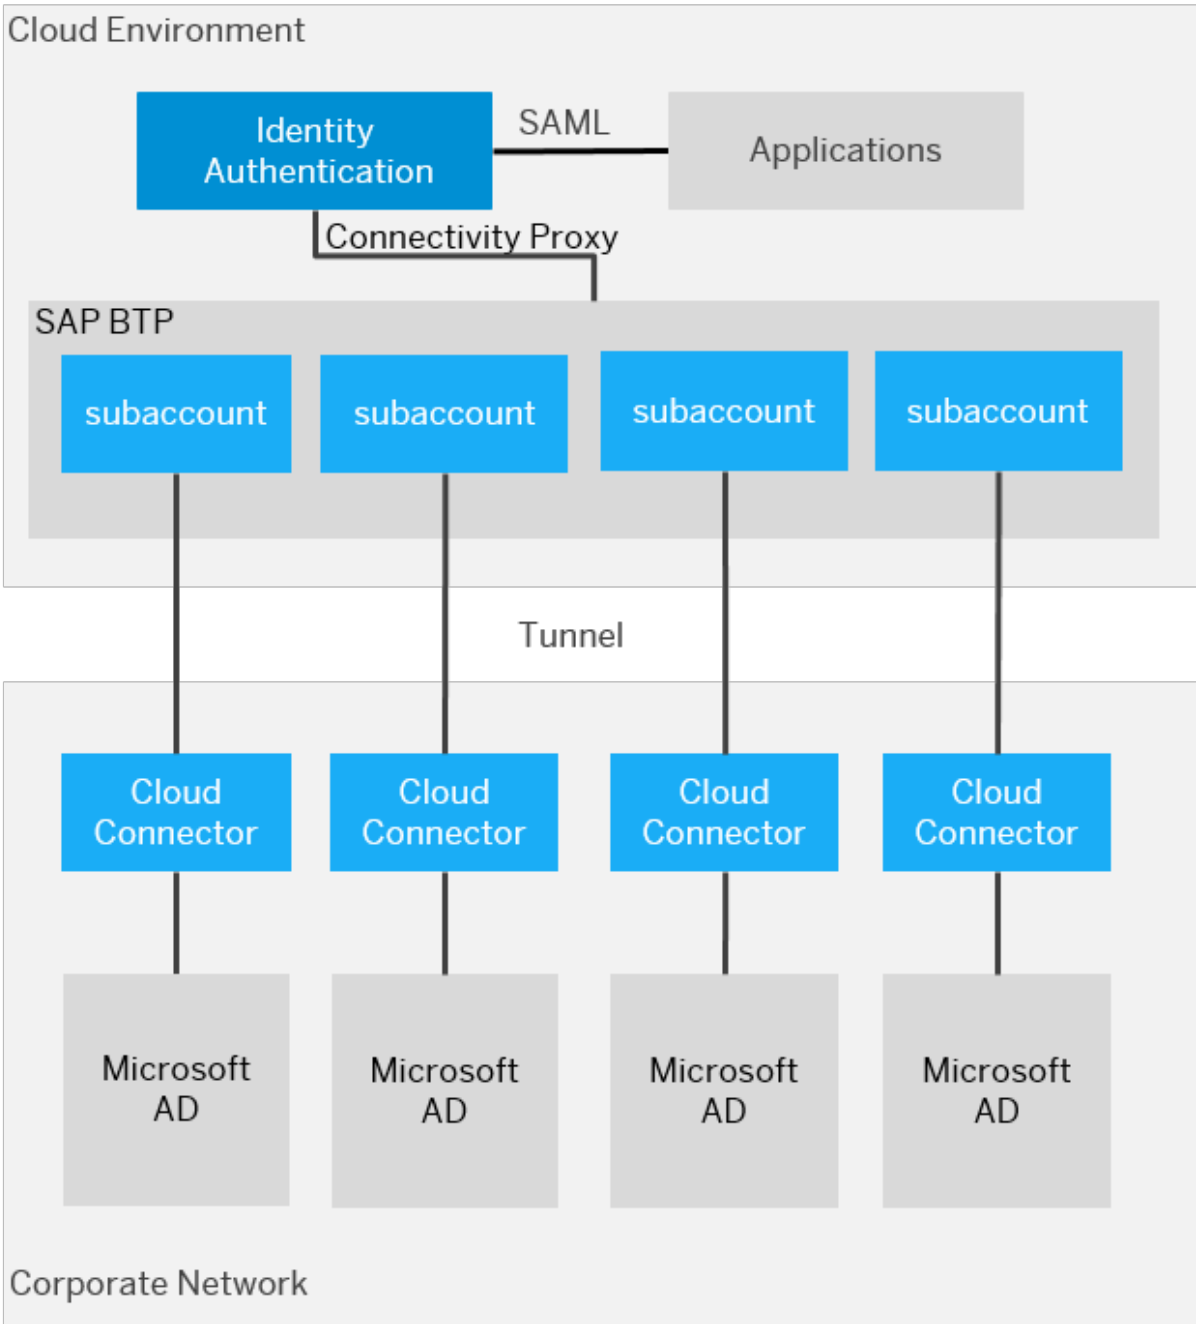
Overview

Identity Authentication can connect with the following corporate user stores:

- Microsoft Active Directory

This scenario works with the connectivity proxy component (logically part of the Connectivity service). For more information about the connectivity proxy, see How the Connectivity Proxy Works

The connection between SAP BTP and the corporate user store is carried out with a Cloud Connector.



Authentication Flow

The *Corporate User Store* option is configured properly. A user tries to access a trusted application for the first time with the on-premise credentials, *Login Name* and *Password* entered correctly. This user is authenticated successfully against the corporate user store. With this initial successful authentication of the user, a partial user record is created in the user store for Identity Authentication. It is created with user details taken from the corporate user store. The cloud user store doesn't copy the user's credentials. For more details about what

data is copied from the corporate user store, see User Records [page 2535]. With subsequent logins, the user is always authenticated against the corporate user store, and the user record is updated.

For the first logon with on-premise credentials, the user enters his or her *Login Name* and a *Password*. For subsequent logins the user can use either his or her *Login Name*, *Email*, or *User ID*, and the *Password*.

> → Remember
>
> If the user has enabled the *Remember me* option, the following limitations are observed:
>
> - when a user is authenticating with remember me cookie, his or her user record in Identity Authentication is not updated.
> - if the user changes his or her password in the corporate network, the remember me cookie is not invalidated.
>
> For more information, see Use the Remember Me Option [page 2774].

> ⓘ Note
>
> The user in the corporate user store must have the `mail` attribute.
>
> The tenant administrator needs to monitor and prevent the coexistence of a cloud and on-premise user with one and the same email address. The tenant administrator has to instruct the users to logon for the first time with their *Login Name*, not with the *Email*.

If a user with a user record in the cloud user store is deleted in the corporate user store, the user can't authenticate using Identity Authentication. The user record for this user remains in the cloud user store, and the tenant administrator can delete it via the administration console for SAP Cloud Identity Services. For more information, see Delete Users [page 2367].

For all users from the corporate user store, a second factor for authentication can be enabled for some applications, or cloud user groups can be assigned. For more details, see Configure Risk-Based Authentication for an Application [page 2007] and Assign Groups to a User [page 2409].

Control Access to Applications and Resources

In the scope of the *Corporate User Store* scenario, you can manage access to applications and their resources based on the groups available in the corporate user store.

The corporate user groups are sent to an application in the SAML 2.0 assertion. `corporate_groups` is the attribute that contains the groups that the user in the corporate user store is assigned to. For more details about how the groups are sent to the application in the SAML 2.0 assertion, see Configuring User Attributes from the Identity Directory [page 1973].

> ⓘ Note
>
> If your application is deployed on the SAP BTP, the corporate user store groups, relevant for the application, and contained in the `corporate_groups` attribute in the SAML 2.0 assertion, can be mapped to assertion-based groups created in SAP BTP cockpit. For more information, see Map Role Collections to User Attributes.

You can also restrict access to applications based on membership in a corporate user group by setting different rules via risk-based authentication. For more information, see Configure Risk-Based Authentication for an Application [page 2007].

1.7.16.1.1.1 User Records

When a user has been successfully authenticated for the first time with the credentials from the corporate user store, a record for that user is created in Identity Authentication. That user record is created with details from the corporate user store. In this record, the user is created with a *User Type*: `employee`, `Password Authentication Provider Type (39)`, and `Password Authentication Provider ID`.

This *User Type* cannot be changed.

For more information about the attributes taken from the Active Directory and their mapping to the user store of Identity Authentication, see **Configure SAP BTP When Connecting to an LDAP User Store** in Configure SAP BTP [page 2522].

Related Information

Security Information [page 2897]

1.7.16.1.1.2 Configure Connection to a Corporate User Store

To configure connection to a corporate user store, you have to make the following configurations in SAP BTP and in Identity Authentication.

For more details about how to configure these systems, see:

- Configure SAP BTP [page 2522]
- Configure Identity Authentication [page 2530]

1.7.16.1.1.3 Configure SAP BTP

Context

The configuration of SAP BTP depends on the type of the user store. You have the option to connect to a Microsoft Active Directory user store.

Data Center Mapping

Identity Authentication Data Center	Cloud Foundry Data Center
eu-nl - Amsterdam	cf-eu10
ap-cn - Shanghai	cf-ap11 - Singapore
na-us - Sterling/Toronto	cf-us10 - US East (VA)

ap-ae - Dubai	cf-eu10 - Europe (Frankfurt)
ap-in - India (Mumbai)	cf-in30 - India (Mumbai)

Configure SAP BTP When Connecting to a Microsoft Active Directory User Store

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. In the SAP BTP cockpit, choose in the navigation area *Services* > *Instances and Subscriptions*.
3. Choose *Create* and select the following info from the dropdowns:
   - *Service* - **`Cloud Identity Services`**
   - *Plan* - **`Connectivity`**

   > **Note**
   >
   > If the *Connectivity* plan is not available check the entitlements configurations of your subaccount. For more information, see Managing Entitlements and Quotas Using the Cockpit.

   The Cloud Identity Services appears under the *Subscriptions* tab.
4. From the *Cloud Service Type* dropdown, choose for what type of tenant (test or productive) you want to use the subaccount.
   - *Test*
   - *Productive* - default value
5. Install an Cloud Connector in your corporate network.

For more information, see Installation.

6. Connect the Cloud Connector between your corporate user store and SAP BTP account.
   - If you haven't used your Cloud Connector before, see Initial Configuration.
   - If you have used your Cloud Connector before, you can start the configuration from Set up Connection Parameters and HTTPS proxy.
7. Connect SAP BTP with your corporate user store.

> ### Note
>
> You have to specify the SAP BTP settings. For more information, see Configure the On-Premise User Store, without the *Prerequisites* section.
>
> The *User Name* field must be in the **`<service_user_name>@<domain>`** format.
>
> For the *User Path* and *Group Path* fields, specify the Microsoft Active Directory tree that contains the users and groups, respectively. For example, if the tree has the following structure:
>
> >
>
> The user and group paths should appear as in the table below:
>
> | | |
> |---|---|
> | User Path | ou=People,dc=example,dc=com |
> | Group Path | ou=People,dc=example,dc=com |

8. **Optional:** Include additional attributes.

> ### Note
>
> You can add the `employeeNumber`, `division`, `department`, and `organization` attributes that are defined in the SCIM Enterprise User Schema Extension.
>
> Cloud Connector uses the SCIM protocol to transfer the data, so the Active Directory attributes are mapped first to the SCIM attributes. When the data is provisioned, the SCIM attributes are mapped to the user store attributes of Identity Authentication.

   a. In your system go to `/sapcc-<version>/config_master/com.sap.core.connectivity.protocol.scim/`
   b. On that level, create a new *idstorage.cfg* file based on the *idstorage_extended_schema.cfg* file which is given as an example in the folder.
   c. Edit the newly created file. For more details, see the information below:

To add new user attributes you have to edit the whole file.

> ⚠ Caution
>
> This file overwrites the configurations you made in Configure the User Store Be careful not to change the user attributes taken from Microsoft Active Directory.

In this section, provide the same information as when you specified the SAP BTP settings in the previous step.

```
 {
 "LDAPServers": [
    {
      "Host": "<The host name of the LDAP server to be contacted>",
      "Port": "<The port where the LDAP service is running. If omitted
then the default LDAP port will be used - 389 for plain connections and
636 for SSL connections>"
    }
 ],
 "UserPath": "<LDAP subtree containing the users. Example
"DC=users,DC=organisation,DC=location">",
 "GroupPath": "<LDAP subtree containing the groups. Example
"DC=groups,DC=organisation,DC=location">",
 "ServiceUser": {
    "Name": "<The name of the user that will be used to establish
communication with the LDAP. In case of Active Directory the user name
should contains Domain suffix, e.g. "john@ACME.COM">",
    "Password": "<Password of this user>"
 },
```

If you want to use SSL, we recommend that you configure this section.

```
 "UseSSL": "<Possible values are "true" or "false". If true then the
communication to LDAP will go over SSL>",
 "IdentityKeystorePath": "<File system path to the client identity
keystore - must be set if the used LDAP server requires client certificate
authentication>",
 "IdentityKeystorePassword": "<The password of the client identity
keystore>",
 "TrustKeystorePath": "<File system path to the trusted CAs keystore -
must be set if UseSSL is true>",
 "TrustKeystorePassword": "<The password of the trusted CAs keystore>",
 "IsActiveDirectory": "<Possible values are "true" (default value if
missing) or "false". "true" indicates that the LDAP server is Active
Directory>",
 "ExcludeUsersAttribute": {
    "AttributeName": "<Name of user attribute that will be used to exclude
some users from the result depending on their type. Attribute is treated
as bitwise. Such attribute for Active Directory is "UserAccountControl">",
    "AttributeMask": "<Bitwise mask represented as decimal value. In case
any of the high bits of this mask match with the corresponding bit of
the value of the above attribute, the user will be excluded from the
result. Example mask for Active Directory is "67121154" - it is the sum
of the following flags ACCOUNTDISABLE(2), WORKSTATION_TRUST_ACCOUNT(4096),
SERVER_TRUST_ACCOUNT(8192) and PARTIAL_SECRETS_ACCOUNT(67108864)>"
 },
```

In this section add the additional attributes `employeeNumber`, `division`, `department`, and `organization`, defined in the SCIM Enterprise User Schema Extension.

```
 {
  "SingularAttributes": [
      {
```

```
            "SCIMAttribute": "userName",

                            "name": "l"
                        }
                    },
                    {
                        "SCIMSubAttribute": "region",
                        "LDAPAttribute": {
                            "name": "st"
                        }
                    },
                    {
                        "SCIMSubAttribute": "postalCode",
                        "LDAPAttribute": {
                            "name": "postalCode"
                        }
                    },
                    {
                        "SCIMSubAttribute": "country",
                        "LDAPAttribute": {
                            "name": "co"
                        }
```

```
                    }
                ]
            }
        ]
    }
]
}
```

d. Save your changes.

e. Restart Cloud Connector to apply the new attributes mapping, which comes from *idstorage.cfg*

This file overwrites the configurations you made in Configuring the User Store.

Next Steps

The following table shows the default mapping between the Active Directory user attributes and the SCIM attributes. It also shows the existing mapping between the SCIM attributes and the attributes in the user store of Identity Authentication.

Detailed Attribute Mapping Between Active Directory and SCIM, and between SCIM and the User Store of Identity Authentication

Microsoft Active Directory Attributes	SCIM Attributes	Identity Authentication User Store Attribute
sAMAccountname	userName	loginName
givenName	givenName	firstName
sn	familyName	lastName
personalTitle	honorificPrefix	title
displayName	displayName	displayName
locale	locale	language
timezone	timeZone	timeZone
employeeNumber	employeeNumber	personnelNumber
division	division	division
department	department	department
costCenter	costCenter	costCenter
company	organization	company
mail	emails.value	mail
telephoneNumber	phoneNumbers[work].value	telephone
facsimileTelephoneNumber	phoneNumbers[fax].value	fax
mobile	phoneNumbers[cell].value	mobile
streetAddress	addresses. streetAddress	street
l	Addresses.locality	city
st	Addresses.region	state

Microsoft Active Directory Attributes	SCIM Attributes	Identity Authentication User Store Attribute
postalCode	Addresses. postalCode	zip
co	Addresses.country	country

> **Note**
>
> The attributes `employeeNumber`, `division`, `department`, `costCenter` in the *Microsoft Active Directory Attributes* column are given as examples. They can differ according to the specific LDAP properties containing these attributes.
>
> If the attribute `language` or `country` comes from the corporate user store in:
>
> - small letters, then the respective keys in the master data service must be updated to small letters to be sent in this way to the service provider.
> - capital letters, then the respective keys in the master data service must be updated to capital letters to be sent in this way to the service provider. By default, `language` and `country` are in capital letters in the master date service.
>
> For more information how to update the master data service, see Change Master Data Texts REST API [page 2860].

Configure Identity Authentication [page 2547]

1.7.16.1.1.4 Configure Identity Authentication

Context

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new source system to the list.
4. Make the corresponding entries in the configuration for the target system you want to add:
   - *Source System*

Configuration	Description
Display Name	(optional) The name of the configuration.

Configuration	Description
Type	Select the *Microsoft Active Directory* type.

- *Configuration*

Configurations	Description
Environment	Cloud Foundry
System ID	This is the name of the system. Provide a name of your choice as *System ID*.
Subaccount domains	Select your SAP BTP subaccount's domain from the drop-down.

5. Save your configuration.

   If the operation is successful, you receive the message `Source system <System ID name> created`.

Results

When the configuration is complete, the user can log in to the application with the on-premise credentials. The first logon requires *Login Name* and password. After successful authentication, a new user record is created in Identity Authentication with type `employee`.

1.7.16.1.2 Corporate User Store (Neo Environment)

Configure corporate user store for applications in the Neo environment to allow users to users to authenticate with their corporate credentials, without the need to use another set of credentials for their cloud access.

> ⓘ Note
>
> The content in this section is only relevant for SAP BTP, Neo environment.

> ⓘ Note
>
> The content in this section is not relevant for China (Shanghai) region.

> → Tip
>
> The recommended configuration of the corporate user store is in the Cloud Foundry environment. The Cloud Foundry setup can be used also for applications that are in the Neo environment. For more information, see Corporate User Store (Cloud Foundry Environment) [page 2519].

Overview

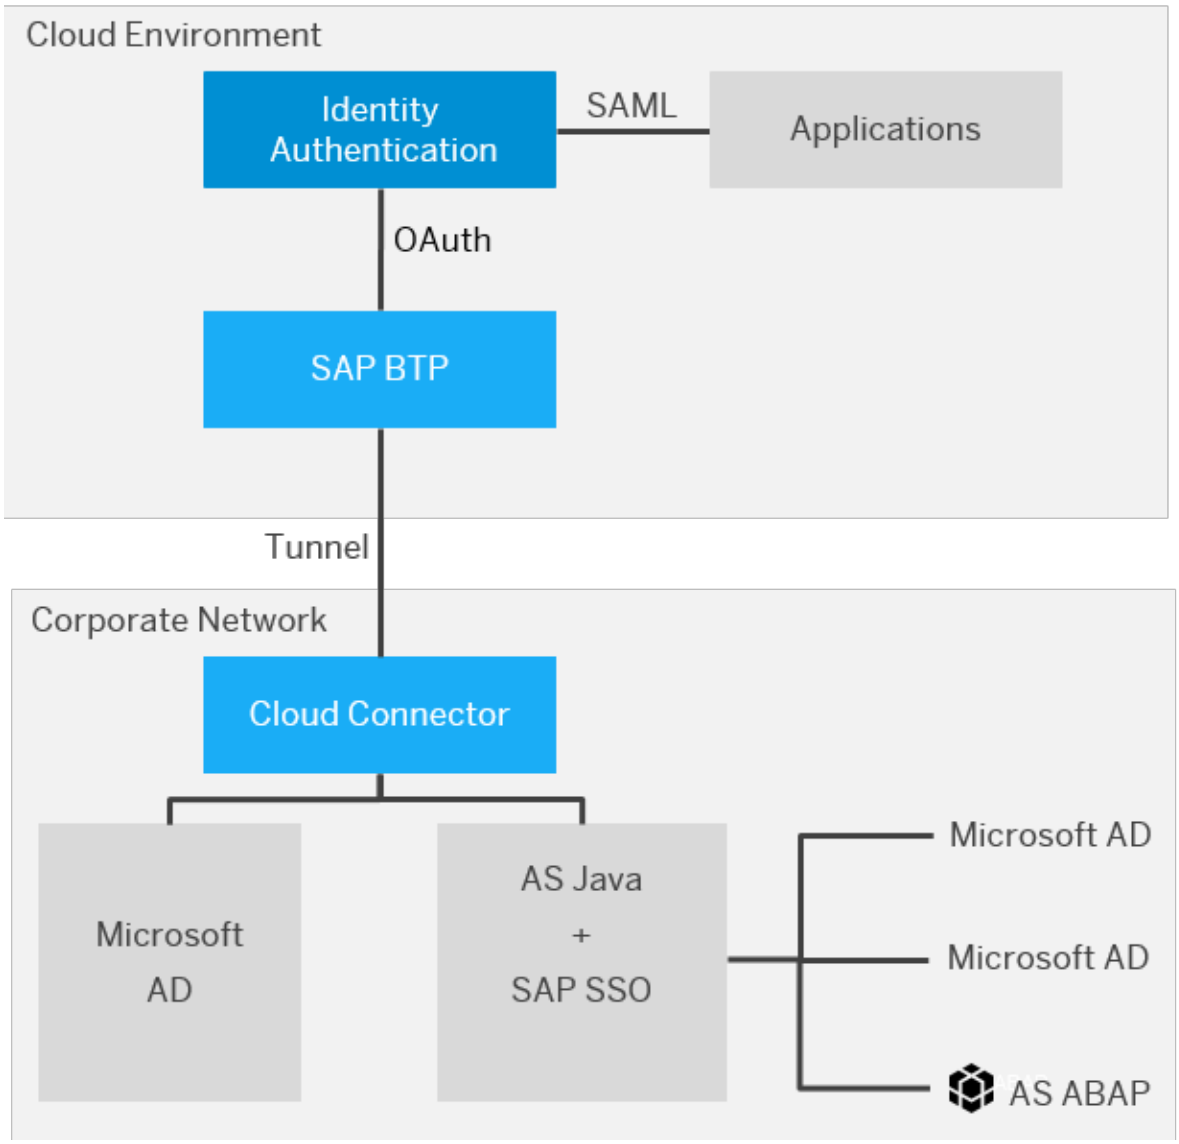
Identity Authentication can connect with the following corporate user stores:

- Microsoft Active Directory
- SAP NetWeaver AS JAVA, with the following variants:
  - SAP NetWeaver AS JAVA - UME
  - Multiple Active Directories connected to SAP NetWeaver AS JAVA - UME
  - SAP NetWeaver AS ABAP connected to SAP NetWeaver AS JAVA - UME

This scenario works with an SAP BTP application named *proxy* and provided by an SAP BTP subaccount named *sci*. The proxy application on SAP BTP uses the OAuth authentication mechanism when communicating with Identity Authentication.

> ⚠ Restriction
>
> The *sci proxy* application is not supported for China.

The connection between SAP BTP and the corporate user store is carried out with an Cloud Connector.



Authentication Flow

The *Corporate User Store* option is configured properly. A user tries to access a trusted application for the first time with the on-premise credentials, *Login Name* and *Password* entered correctly. This user is authenticated successfully against the corporate user store. With this initial successful authentication of the user, a partial user record is created in the user store for Identity Authentication. It is created with user details taken from the corporate user store. The cloud user store does not copy the user's credentials. For more details about what data is copied from the corporate user store, see User Records [page 2535]. With subsequent logins, the user is always authenticated against the corporate user store, and the user record is updated.

For the first logon with on-premise credentials, the user enters his or her *Login Name* and a *Password*. For subsequent logins the user can use either his or her *Login Name*, *Email*, or *User ID*, and the *Password* .

→ Remember

If the user has enabled the *Remember me* option, the following limitations are observed:

- when a user is authenticating with remember me cookie, his or her user record in Identity Authentication is not updated.
- if the user changes his or her password in the corporate network, the remember me cookie is not invalidated.

For more information, see Use the Remember Me Option [page 2774].

ⓘ Note

The user in the corporate user store must have the `mail` attribute.

The tenant administrator needs to monitor and prevent the coexistence of a cloud and on-premise user with one and the same email address. The tenant administrator has to instruct the users to logon for the first time with their *Login Name*, not with the *Email*.

If a user with a user record in the cloud user store is deleted in the corporate user store, the user cannot authenticate using Identity Authentication. The user record for this user remains in the cloud user store, and the tenant administrator can delete it via the administration console for SAP Cloud Identity Services. For more information, see Delete Users [page 2367].

For all users from the corporate user store, a second factor for authentication can be enabled for some applications, or cloud user groups can be assigned. For more details, see Configure Risk-Based Authentication for an Application [page 2007] and Assign Groups to a User [page 2409].

Control Access to Applications and Resources

In the scope of the *Corporate User Store* scenario, you can manage access to applications and their resources based on the groups available in the corporate user store.

The corporate user groups are sent to an application in the SAML 2.0 assertion. `corporate_groups` is the attribute that contains the groups that the user in the corporate user store is assigned to. For more details about how the groups are sent to the application in the SAML 2.0 assertion, see Configuring User Attributes from the Identity Directory [page 1973].

ⓘ Note

If your application is deployed on the SAP BTP, the corporate user store groups, relevant for the application, and contained in the `corporate_groups` attribute in the SAML 2.0 assertion, can be mapped to assertion-based groups created in SAP BTP cockpit. For more information, see the *4. (If Using an Identity Provider) Define the Group-to-Role Mapping* section in Managing Roles.

You can also restrict access to applications based on membership in a corporate user group by setting different rules via risk-based authentication. For more information, see Configure Risk-Based Authentication for an Application [page 2007].

1.7.16.1.2.1 User Records

When a user has been successfully authenticated for the first time with the credentials from the corporate user store, a record for that user is created in Identity Authentication. That user record is created with details from the corporate user store. In this record, the user is created with a *User Type* `employee`. This *User Type* cannot be changed.

For more information about the attributes taken from the Active Directory and their mapping to the user store of Identity Authentication, see **Configure SAP BTP When Connecting to an LDAP User Store** in Configure SAP BTP [page 2535].

Related Information

Security Information [page 2897]

1.7.16.1.2.2 Configure Connection to a Corporate User Store

To configure connection to a corporate user store, you have to make the following configurations in SAP BTP and in Identity Authentication.

For more details about how to configure these systems, see:

- Configure SAP BTP [page 2535]
- Configure Identity Authentication [page 2547]

1.7.16.1.2.3 Configure SAP BTP

Context

The configuration of SAP BTP depends on the type of the user store. You have two options: Microsoft Active Directory user store and SAP NetWeaver AS Java user store.

Configure SAP BTP When Connecting to a Microsoft Active Directory User Store

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.

2. In the SAP BTP cockpit, choose *Services in the navigation area* > *Identity Authentication Add-On* > *Enable in the detailed view of the service*.

   This enables the extension service of Identity Authentication named *proxy* and provided by an SAP BTP subaccount named *sci*.

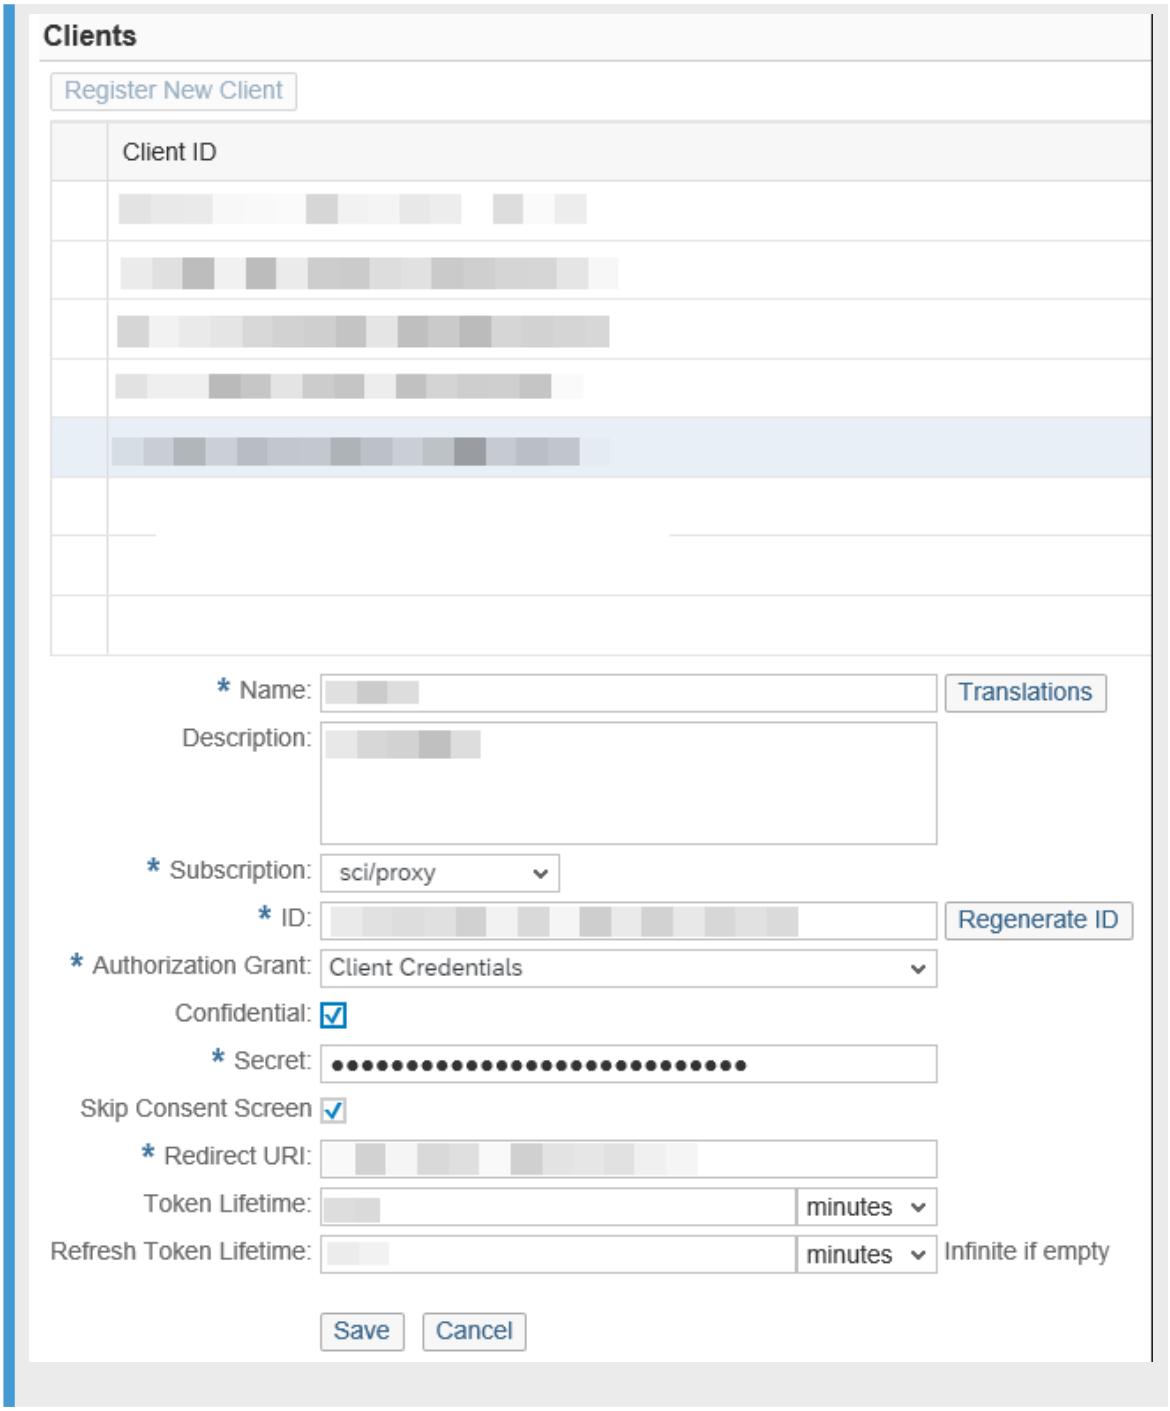
   > ⚠ Caution
   >
   > If you don't see the *Identity Authentication Add-On* tile in the cockpit, you need to report an incident with a subject "Enable Corporate User Store Feature" on SAP Support Portal Home under the component `BC-IAM-IDS`. You have to provide information about your SAP BTP subaccount name and region.

3. In your subaccount on SAP BTP, register an OAuth client for the subscribed *proxy* application provided by the *sci* subaccount.

   The procedure is described in the documentation of SAP BTP in the link below.

   > ⓘ Note
   >
   > Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

   > ⓘ Note
   >
   > Since Identity Authentication will create the subscription to the *proxy* application, the *Prerequisites* section in the respective document isn't relevant for the current scenario.
   >
   > For the *Authorization Grant* field in the SAP BTP cockpit, choose *Client Credentials* from the dropdown, and for the *Subscription* field, choose *sci/proxy*.



For more information about how to register an OAuth client, see Register an OAuth Client.

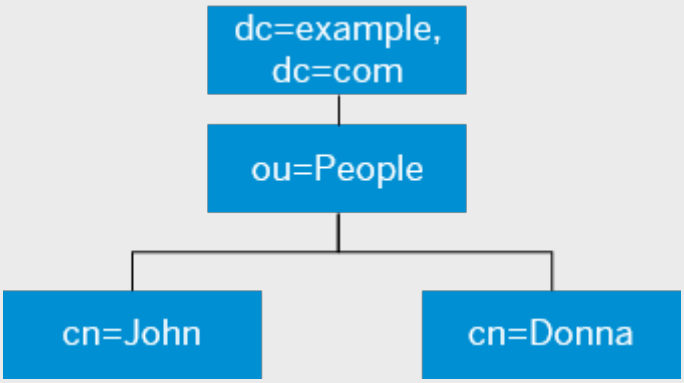
4. Install a Cloud Connector in your corporate network.

   For more information, see Installation.

5. Connect the Cloud Connector with your SAP BTP account.
   - If you haven't used your Cloud Connector before, see Initial Configuration.
   - If you have used your Cloud Connector before, you can start the configuration from Set up Connection Parameters and HTTPS proxy.

6. Connect SAP BTP with your corporate user store.

> **Note**
>
> You have to specify the SAP BTP settings. The *Prerequisites* section in the document describing the configuration is already configured for the *proxy* application, and you should proceed with the configuration steps. For more information, see Configure the User Store.
>
> The *User Name* field must be in the **`<service_user_name>@<domain>`** format.
>
> For the *User Path* and *Group Path* fields, specify the Microsoft Active Directory tree that contains the users and groups, respectively. For example, if the tree has the following structure:



> The user and group paths should appear as in the table below:

User Path	ou=People,dc=example,dc=com
Group Path	ou=People,dc=example,dc=com

7. **Optional:** Include additional attributes.

> **Note**
>
> You can add the `employeeNumber`, `division`, `department`, and `organization` attributes that are defined in the SCIM Enterprise User Schema Extension.
>
> Cloud Connector uses the SCIM protocol to transfer the data, so the Active Directory attributes are mapped first to the SCIM attributes. When the data is provisioned, the SCIM attributes are mapped to the user store attributes of Identity Authentication.

a. In your system go to `/sapcc-<version>/config_master/com.sap.core.connectivity.protocol.scim/`
b. On that level, create a new *idstorage.cfg* file based on the *idstorage_extended_schema.cfg* file which is given as an example in the folder.
c. Edit the newly created file. For more details, see the information below:

   To add new user attributes you have to edit the whole file.

> ⚠ Caution
>
> This file overwrites the configurations you made in Configure the User Store Be careful not to change the user attributes taken from Microsoft Active Directory.

In this section, provide the same information as when you specified the SAP BTP settings in the previous step.

```
 {
 "LDAPServers": [
    {
      "Host": "<The host name of the LDAP server to be contacted>",
      "Port": "<The port where the LDAP service is running. If omitted
then the default LDAP port will be used - 389 for plain connections and
636 for SSL connections>"
    }
 ],
 "UserPath": "<LDAP subtree containing the users. Example
"DC=users,DC=organisation,DC=location">",
 "GroupPath": "<LDAP subtree containing the groups. Example
"DC=groups,DC=organisation,DC=location">",
 "ServiceUser": {
    "Name": "<The name of the user that will be used to establish
communication with the LDAP. In case of Active Directory the user name
should contains Domain suffix, e.g. "john@ACME.COM">",
    "Password": "<Password of this user>"
 },
```

If you want to use SSL, we recommend that you configure this section.

```
 "UseSSL": "<Possible values are "true" or "false". If true then the
communication to LDAP will go over SSL>",
 "IdentityKeystorePath": "<File system path to the client identity
keystore - must be set if the used LDAP server requires client certificate
authentication>",
 "IdentityKeystorePassword": "<The password of the client identity
keystore>",
 "TrustKeystorePath": "<File system path to the trusted CAs keystore -
must be set if UseSSL is true>",
 "TrustKeystorePassword": "<The password of the trusted CAs keystore>",
```

In this section add the additional attributes `employeeNumber`, `division`, `department`, and `organization`, defined in the SCIM Enterprise User Schema Extension.

                        "SCIMSubAttribute": "value",
                        "LDAPAttribute": {
                            "name": "mail"
                        }
                    }
                ]
             }
         ]
      },
      {
         "SCIMAttribute": "phoneNumbers",
         "values": [
             {
                 "type": "work",
                 "primary": "true",
                 "mappings": [
                     {
                         "SCIMSubAttribute": "value",
                         "LDAPAttribute": {
                             "name": "telephoneNumber"
                         }
                     }
                 ]
             },
             {
                 "type": "fax",
                 "mappings": [
                     {
                         "SCIMSubAttribute": "value",
                         "LDAPAttribute": {
                             "name": "facsimileTelephoneNumber"
```

```
                        }
                    }
                ]
            },
            {
                "type": "cell",
                "mappings": [
                    {
                        "SCIMSubAttribute": "value",
                        "LDAPAttribute": {
                            "name": "mobile"
                        }
                    }
                ]
            }
        ]
    },
    {
        "SCIMAttribute": "addresses",
        "values": [
            {
                "primary": "true",
                "mappings": [
                    {
                        "SCIMSubAttribute": "streetAddress",
                        "LDAPAttribute": {
                            "name": "streetAddress"
                        }
                    },
                    {
                        "SCIMSubAttribute": "locality",
                        "LDAPAttribute": {
                            "name": "l"
                        }
                    },
                    {
                        "SCIMSubAttribute": "region",
                        "LDAPAttribute": {
                            "name": "st"
                        }
                    },
                    {
                        "SCIMSubAttribute": "postalCode",
                        "LDAPAttribute": {
                            "name": "postalCode"
                        }
                    },
                    {
                        "SCIMSubAttribute": "country",
                        "LDAPAttribute": {
                            "name": "co"
                        }
                    }
                ]
            }
        ]
    }
]
}
```

d. Save your changes.

e. Restart Cloud Connector to apply the new attributes mapping, which comes from *idstorage.cfg*

This file overwrites the configurations you made in Configuring the User Store.

Next Steps

The following table shows the default mapping between the Active Directory user attributes and the SCIM attributes. It also shows the existing mapping between the SCIM attributes and the attributes in the user store of Identity Authentication.

Detailed Attribute Mapping Between Active Directory and SCIM, and between SCIM and the User Store of Identity Authentication

Microsoft Active Directory Attributes	SCIM Attributes	Identity Authentication User Store Attribute
sAMAccountname	userName	loginName
givenName	givenName	firstName
sn	familyName	lastName
personalTitle	honorificPrefix	title
displayName	displayName	displayName
locale	locale	language
timezone	timeZone	timeZone
employeeNumber	employeeNumber	personnelNumber
division	division	division
department	department	department
costCenter	costCenter	costCenter
company	organization	company
mail	emails.value	mail
telephoneNumber	phoneNumbers[work].value	telephone
facsimileTelephoneNumber	phoneNumbers[fax].value	fax
mobile	phoneNumbers[cell].value	mobile
streetAddress	addresses. streetAddress	street
l	Addresses.locality	city
st	Addresses.region	state
postalCode	Addresses. postalCode	zip
co	Addresses.country	country

> ### Note
>
> The attributes `employeeNumber`, `division`, `department`, `costCenter` in the *Microsoft Active Directory Attributes* column are given as examples. They can differ according to the specific LDAP properties containing these attributes.
>
> If the attribute `language` or `country` comes from the corporate user store in:
>
> - small letters, then the respective keys in the master data service must be updated to small letters to be sent in this way to the service provider.

- capital letters, then the respective keys in the master data service must be updated to capital letters to be sent in this way to the service provider. By default, `language` and `country` are in capital letters in the master date service.

For more information how to update the master data service, see Change Master Data Texts REST API [page 2860].

Configure Identity Authentication [page 2547]

Configure SAP BTP When Connecting to an SAP NW AS Java User Store

Prerequisites

- You have an SAP NetWeaver 7.2 or higher Application Server for the Java system.
- You have SAP Single Sign-On (SAP SSO) 2.0 or higher installed in your system landscape.
- You have installed and deployed federation software component archive (SCA) from SAP Single Sign-On (SSO) 2.0. For more information, see Downloading and Installing the Federation Software.

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. In the SAP BTP cockpit, choose *Services in the navigation area* > *Identity Authentication Add-On* > *Enable in the detailed view of the service*.

   This will enable the extension service of Identity Authentication named *proxy* and provided by an SAP BTP subaccount named *sci*.

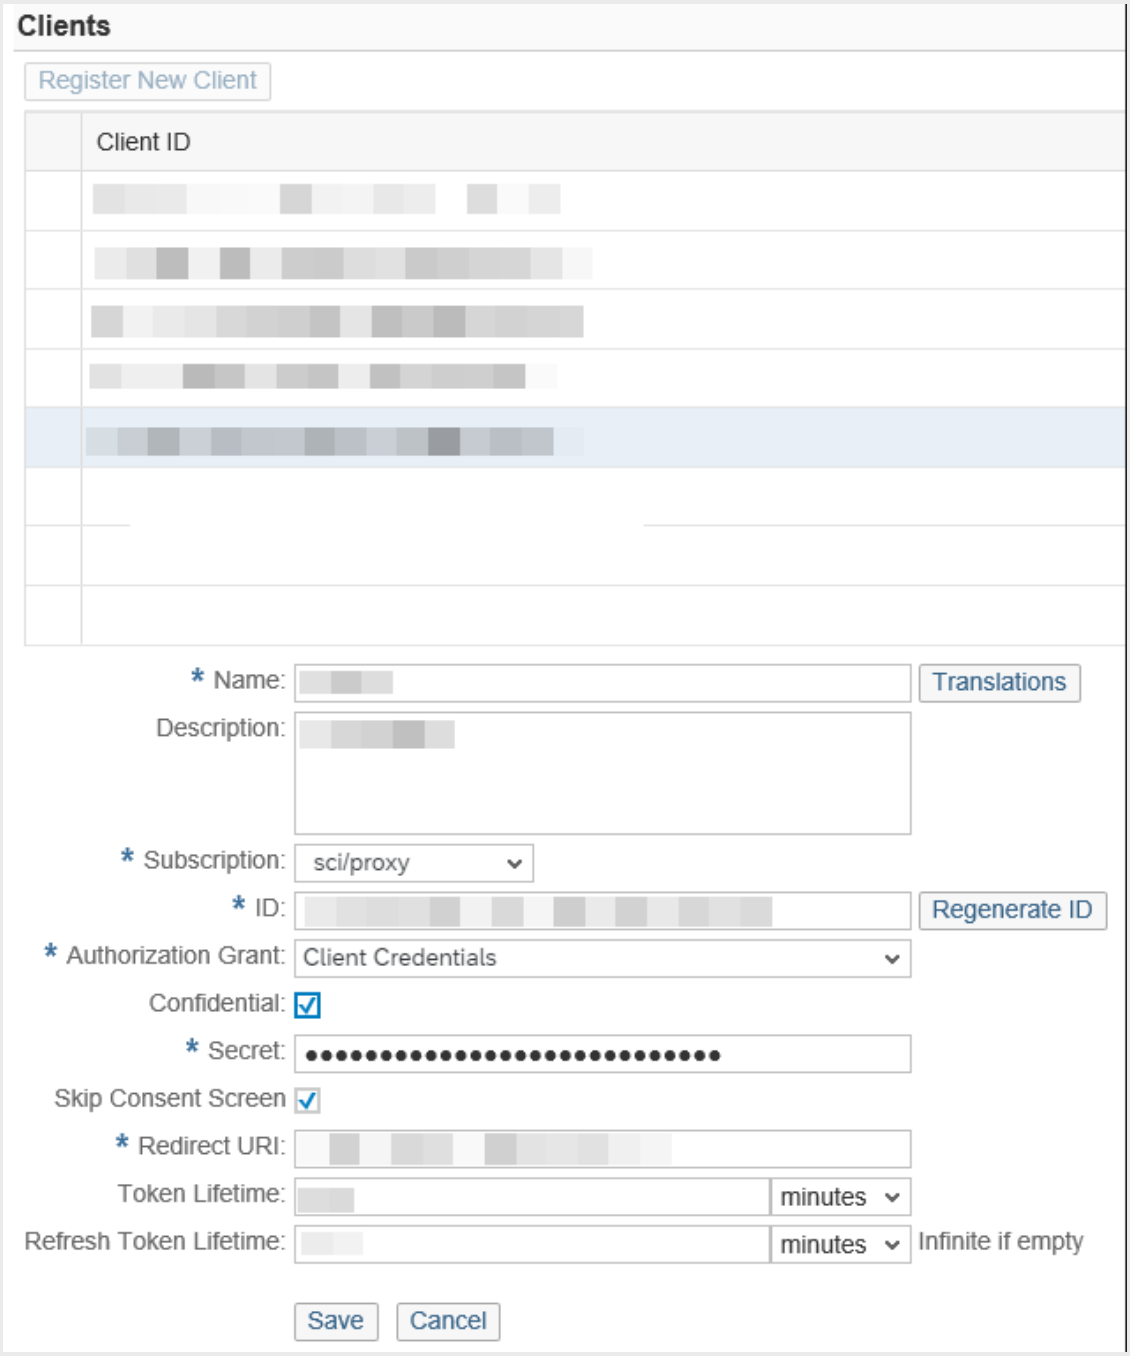
   > ⚠ Caution
   >
   > If you don't see the *Identity Authentication Add-On* tile in the cockpit, you need to report an incident with a subject "Enable Corporate User Store Feature" on SAP Support Portal Home under the component **BC-IAM-IDS**. You have to provide information about your SAP BTP subaccount name and region.

3. In your subaccount on SAP BTP, register an OAuth client for the subscribed *proxy* application provided by the *sci* subaccount.

   The procedure is described in the documentation of SAP BTP in the link below.

   > ⓘ Note
   >
   > Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

> ### Note
>
> Since Identity Authentication will create the subscription to the *proxy* application, the *Prerequisites* section in the respective document isn't relevant for the current scenario.
>
> For the *Authorization Grant* field in the SAP BTP cockpit, choose *Client Credentials* from the dropdown, and for the *Subscription* field, choose *sci/proxy*.



For more information about how to register an OAuth client, see Register an OAuth Client.

4. Install a Cloud Cloud Connector in your corporate network.

For more information, see Installation.

5. Connect the Cloud Connector with your SAP BTP account.
   - If you haven't used your Cloud Connector before, see Initial Configuration.
   - If you have used your Cloud Connector before, you can start the configuration from Set up Connection Parameters and HTTPS proxy.
6. Connect SAP BTP with your corporate user store.
   a. In the configuration of Cloud Connector, configure the host mapping to the on-premise system. For more information, see Configure Access Control (HTTP). For the *Limiting the Accessible Services for HTTP(S)* section, be sure that the `URL Path` is `/scim/v1`, and `Path and all Subpaths` radio button is chosen for `Access Policy`.
   b. Create a destination to the on-premise system. In the SAP BTP cockpit, choose *Services in the navigation area* > *Identity Authentication Add-On* > *Configure Identity Authentication Add-On* > *New Destination*.

> **Note**
>
> When configuring the destination to the on-premise system, make sure of the following:
>
> - The *Name* is **`SAPCloudIdentityUserStore`**.
> - The *Type* is **`HTTP`**.
> - The *URL* of the destination, the host name, and the port should coincide with the virtual host name and virtual port from the setup of the access control in Cloud Connector.
>
>   > → Remember
>   >
>   > The protocol of the *URL* must be **`HTTP`**.
>
>   The *URL* of the destination should be in the following pattern: *http:// <Virtual host configured in Cloud Connector>:<virtual Port>/scim/v1/*
> - The *Proxy Type* is **`OnPremise`**.
> - The *Authentication* is **`BasicAuthentication`**.
>
> For more information, see Using an SAP System as an On-Premise User Store. Since Identity Authentication has already deployed the *proxy* application, you should start from the **2. Configure the On-Premise System** section in the documentation.

Next Steps

Configure Identity Authentication [page 2547]

1.7.16.1.2.4 Configure Identity Authentication

Context

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new source system to the list.
4. Make the corresponding entries in the configuration for the target system you want to add:
   - *Source System*

Configuration	Description
Display Name	(optional) The name of the configuration.
Type	Select the *Microsoft Active Directory* type.

   - *Configuration*

Configurations	Description
Environment	Neo
Data Center	Select your SAP BTP subaccount's region.
Technical Name	The *Technical Name* must match your SAP BTP subaccount *Technical Name*.
Client ID	The *Client ID* must match the *ID* registered on SAP BTP under the *OAuth Settings* tab for your subaccount.
Client Secret	The *Client Secret* must match the *Secret* registered on SAP BTP under the *OAuth Settings* tab for your subaccount.

5. Save your configuration.

   If the operation is successful, you receive the message `Source system <System ID name> created`.

Results

When the configuration is complete, the user can log in to the application with the on-premise credentials. The first logon requires *Login Name* and password. After successful authentication, a new user record is created in Identity Authentication with type `employee`.

1.7.16.2 Kerberos Authentication

Configure Kerberos authentication for Identity Authentication to allow users to log on without a username and password when they are in the corporate network, and enable this authentication to allow users to log on to an application from the corporate network without entering their username and password.

- Configure Kerberos Authentication [page 2548]
- Enable or Disable Kerberos Authentication for an Application [page 2556]

1.7.16.2.1 Configure Kerberos Authentication

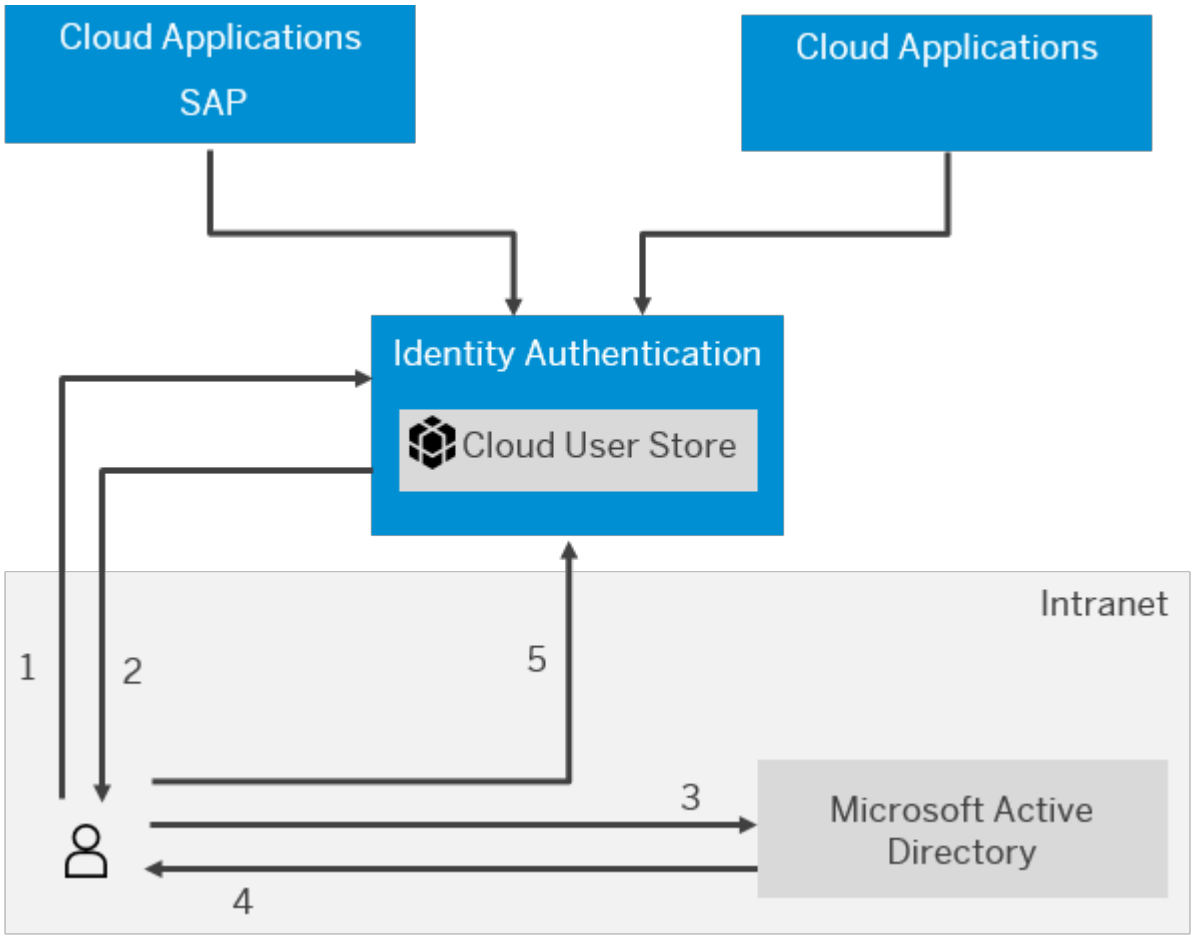
Overview

You configure Kerberos authentication for Identity Authentication to allow users to log on without a username and password when they are in the corporate network. Identity Authentication supports Kerberos with Simple and Protected GSS-API Negotiation Mechanism (SPNEGO).

Kerberos authentication with Identity Authentication requires the following systems:

- Web client
  The web client requests a protected resource of an application configured to use Identity Authentication as an identity provider. It authenticates against the Key Distribution Center (KDC). For example, users can use the web browser to access cloud applications using Identity Authentication.
- Key Distribution Center (KDC)
  It authenticates the user and grants a ticket that is used for the communication between the web client and Identity Authentication.
- Identity Authentication
  Identity Authentication accepts the ticket issued by the KDC and checks the authenticating user in its cloud user store.

The communication flow is as follows:



1. A user accesses a cloud application on his or her web browser (web client) in the corporate network, and the web client sends a request to Identity Authentication.
2. Identity Authentication returns a response with status code *401 Unauthorized* .
   The response contains a *WWW-Authenticate: Negotiate* header.
3. The Web client requests a Kerberos ticket from the Microsoft Active Directory (KDC).
4. The Microsoft Active Directory (KDC) responds with the ticket.
5. The Web client sends the ticket to Identity Authentication.
6. Identity Authentication validates the ticket, checks that the user exists in its cloud user store by the user's logon name, and authenticates the user.

Related Information

Kerberos: The Network Authentication Protocol

1.7.16.2.1.1 Prerequisites

- You have configured the web browser (web client) to use Kerberos authentication.
  For more information about this procedure, see the corresponding browser (client) documentation.

  > → Tip
  >
  > This setting is usually found under the *Local Intranet* tab or the *Trusted Sites* list in the browser. Search on the Internet or in your browser documentation for information about how Kerberos authentication is enabled.

- You have a tenant for Identity Authentication.
- The trust with the service provider of Identity Authentication is configured.
  For more information, see Integrating the Service [page 2910].
- The users logging on with Kerberos authentication exist in the cloud user store with the required details. Each user has to have a logon name as a user attribute. This is specified under the *loginName* column in the imported CSV file. For details, see Related Information.

Related Information

Import or Update Users for a Specific Application [page 2348]

1.7.16.2.1.2 Configure Key Distribution Center (KDC)

Context

This procedure is performed by the domain administrator. If you are not a domain administrator, skip to the next section.

Procedure

1. Create a service user in KDC (in Microsoft Active Directory for example).

   > ⓘ Note
   >
   > A service user is associated with one tenant only.

2. Generate a keytab file and provide it to the tenant administrator.

   When you create the keytab file, the password you specify for the service user is used to generate a key. A setting on the service user also allows you to configure a key type to be derived and used for the

encryption of the Kerberos ticket. You have to provide this keytab file as well as the key type to the tenant administrator so that he or she can configure Identity Authentication.

The key type has to match the encryption type of the corresponding service user that contains the tenant as a service principal name.

Key Type	Supported by Identity Authentication
RC4_HMAC	Yes
AES128_CTS_HMAC_SHA1_96	Yes
AES256_CTS_HMAC_SHA1_96	Yes
NTLMSSP	No
NEGOEXT	No

For more information about these key types, see RFC 4757 and RFC 3962.

> ⚠ Caution
>
> The realm you specify to generate the keytab file has to be in capital letters.

> ✤ Example
>
> You can derive the key by using your *Java* installation. To derive the key, proceed as follows:
>
> 1. In the command prompt, run the `ktab -help` command to see the list of available commands.
>
>   > → Tip
>   >
>   > Go to your Java `bin` folder or set the Java path as an environment variable.
>
> 2. Enter `ktab -a <service user>@<realm> -k <path>\<keytab filename>.ktab` with `<realm>` in capital letters to create a new keytab file .
>   You are also prompted to enter the service user password that is used to derive the key.

3. Register a service principal name (SPN) associated with the service user for the host name used to access Identity Authentication. The SPN has to be unique.

> ✤ Example
>
> The command line `setspn -A HTTP/<tenantID>.accounts.ondemand.com <service user>` registers an SPN for the *<tenantID>.accounts.ondemand.com* host associated with the service user.

> ⚠ Caution
>
> If you have one of the following combination of an operating system and web browser:
>
> | Operating System | Browser |
> |---|---|
> | Microsoft Windows 10 | Microsoft Internet Explorer 11 |
> | Microsoft Windows | Google Chrome |

Operating System	Browser
Microsoft Windows	Mozilla Firefox

you must ensure a registration of an SPN for the root host name of Identity Authentication.

Root host names per tenant locations:

Host Names

Country/Region	Data Center	Infrastructure	Host Name
Australia	Australia (Sydney)	SAP / Azure	`ap.accounts.ondemand.com.cloud.sap.akadns.net`
Brazil	Brazil (São Paulo)	AWS	`br.accounts.ondemand.com.cloud.sap.akadns.net`
China	China (Shanghai)	SAP	`accounts.sapcloud.cn.cloud.sap.akadns.net`
Europe	Germany (Frankfurt)	AWS	`aws-eu-de.accounts.ondemand.com.cloud.sap.akadns.net`
Europe	Europe (Frankfurt / Amsterdam))	SAP	`accounts.ondemand.com.cloud.sap.akadns.net`
India	India (Mumbai)	AWS	`aws-ap-in.accounts.ondemand.com.cloud.sap.akadns.net`
Israel	Israel (Tel Aviv)	Google Cloud	`il.accounts.ondemand.com.cloud.sap.akadns.net`
Japan	Japan (Tokyo / Osaka)	SAP	`jp.accounts.ondemand.com.cloud.sap.akadns.net`
North America (Canada Central)	Canada (Toronto)	Azure	`azr-na-ca.accounts.ondemand.com.cloud.sap.akadns.net`
Saudi Arabia (SA1)	Saudi Arabia (Dammam)	Google Cloud	`sa.accounts.ondemand.com.cloud.sap.akadns.net`

Country/Region	Data Center	Infrastructure	Host Name
Saudi Arabia (SA2)	Saudi Arabia (Dammam) - Regulated	Google Cloud	`sa2.accounts.ondemand.com.cloud.sap.akadns.net`
Singapore	Singapore	AWS	`aws-ap-se-1.accounts.ondemand.com.cloud.sap.akadns.net`
South Korea	South Korea (Seoul)	AWS	`aws-ap-kr.accounts.ondemand.com.cloud.sap.akadns.net`
Switzerland	Switzerland (Zürich)	Azure	`azr-eu-ch.accounts.ondemand.com.cloud.sap.akadns.net`
United Arab Emirates	United Arab Emirates (Dubai)	SAP	`azr-ap-ae.accounts.ondemand.com.cloud.sap.akadns.net`
United Kingdom	United Kingdom (London)	Azure	`uk.accounts.ondemand.com.cloud.sap.akadns.net`
US (North America East)	USA (Sterling, VA / N. Virginia)	SAP	`us-east.accounts.ondemand.com.cloud.sap.akadns.net`
US East **Note** Trial environment.	Trial (USA)	Azure	`trial-accounts.ondemand.com.cloud.sap.akadns.net`
US West	USA (Quincy, WA)	Azure	`azr-us-we.accounts.ondemand.com.cloud.sap.akadns.net`

Example

The command line `setspn -A HTTP/accounts.ondemand.com.cloud.sap.akadns.net <service user>` registers an SPN for the root host *accounts.ondemand.com.cloud.sap.akadns.net* associated with the service user.

1.7.16.2.1.3 Configure Identity Authentication

Prerequisites

You are assigned the *Manage Tenant Configuration* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

This procedure is performed by the tenant administrator.

Procedure

1. Extract the key from the keytab file provided by the domain administrator.

   > ### Example
   >
   > You can extract the key by using your *Java* installation.
   >
   > 1. In the command prompt, run the `ktab -help` command to see the list of available commands.
   >
   >   > ### → Tip
   >   >
   >   > Go to your Java `bin` folder or set the Java path as an environment variable.
   >
   > 2. Enter `klist -e -f -k -K <path>\<keytab filename>.ktab` to list the derived keys corresponding to the key types.
   > 3. Copy the key according to the number of the provided key type: *23* corresponds to *RC4*, *17* corresponds to *AES128*, and *18* corresponds to *AES256*.

2. Access the tenant's administration console for SAP Cloud Identity Services by using the console's URL.

   > ### Note
   >
   > The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.

3. Under *Applications and Resources*, choose the *Tenant Settings* tile.

   At the top of the page, you can view the administrative and license relevant information of the tenant.

4. Choose the *SPNEGO* list item.
5. Choose *+Add* and enter the following information:
   - Realm
     The Kerberos realm (domain) which the SPN and service user reside in.

> ⓘ Note
>
> The realm (domain) has to be in capital letters.

- Key type
  The key type has to match the encryption type of the corresponding service user that contains the tenant as a service principal name.

Key Type	Supported by Identity Authentication
RC4_HMAC	Yes
AES128_CTS_HMAC_SHA1_96	Yes
AES256_CTS_HMAC_SHA1_96	Yes
NTLMSSP	No
NEGOEXT	No

  For more information about these key types, see RFC 4757 and RFC 3962.

- Key
  The key derived with the password of the service user in the KDC.
- IP white list
  A comma-separated list of ranges of the web client's IPs or proxies allowed for the Kerberos authentication. The IP white list has to contain ranges in Classless Inter-Domain Routing (CIDR) notation.

> ⓘ Note
>
> By default the field is empty, which means any client IP is allowed.

> ✤ Example
>
> Enter *123.45.67.1/24, 189.101.112.1/16* to allow the web client to use any client IP starting with 123.45.67 or with 189.101.

6. Choose *+Add*.

   If the operation is successful, you receive the message `SPNEGO settings saved`.

> → Tip
>
> To update the saved settings, choose *Edit* and save your changes.

Next Steps

Enable Kerberos authentication for specific applications. For more information, see Enable or Disable Kerberos Authentication for an Application [page 2556].

1.7.16.3 Enable or Disable Kerberos Authentication for an Application

You enable Kerberos authentication to allow users to log on to an application from the corporate network without entering their username and password.

Prerequisites

You have configured Kerberos authentication for the tenant. For more information, see Configure Kerberos Authentication [page 2548].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Authentication and Access* tab.
5. Under *AUTHENTICATION*, enable or disable SPNEGO authentication.

   Once the application has been updated, the system displays the message `Application <name of application> updated`.

Related Information

Create a New Application [page 1922]

1.7.16.4 Corporate Identity Providers

Initially, Identity Authentication is set as the default identity provider for the applications. This section describes the scenarios in which Identity Authentication acts as a proxy to delegate the authentication to a corporate identity provider.

A corporate identity provider is an enterprise-controlled service that verifies user identities and issues standards-based security tokens (such as SAML or OpenID Connect tokens) for single sign-on to corporate

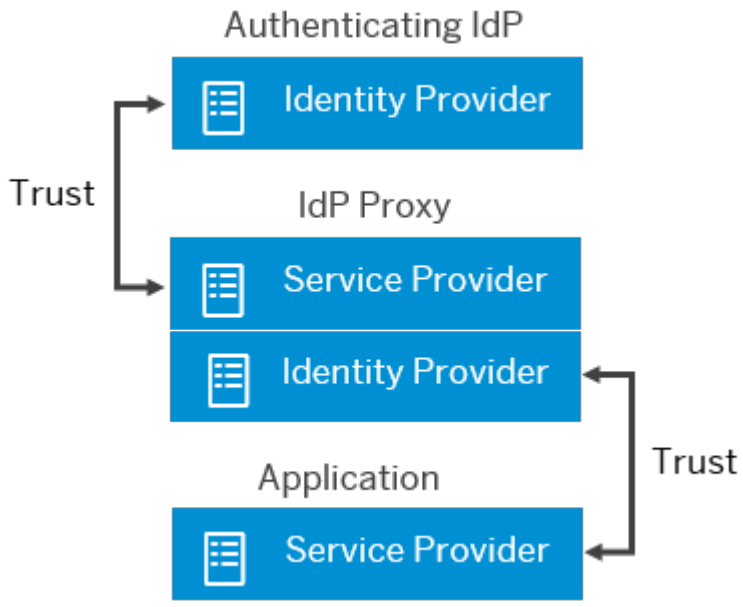
applications. It centralizes authentication and access policies (such as MFA and conditional access), manages trust with service providers, and can federate with other identity providers to provide a consistent, secure sign-in experience across the enterprise.

Identity Provider Proxy Overview

An identity provider can function as a proxy for another identity provider. An identity provider proxy enables you to create structures of trust relationships that ultimately simplify the management of your applications.

A proxy relationship involves the following participants:

- Corporate Identity Provider
  The identity provider proxy trusts the authenticating identity provider.
- Identity Provider Proxy
  The identity provider proxy is both an identity provider and a service provider. The service provider of the identity provider proxy trusts the authenticating identity provider.
- Application
  A service provider hosts a service that users want to access. This service provider trusts the identity provider of the identity provider proxy.



There's no direct trust relationship between the authenticating identity provider and the service provider that the user is trying to access.

Identity Authentication acting as a proxy can use a SAML 2.0 or an OpenID Connect (OIDC) identity provider as an external authenticating authority for the application. The choice of one or the other protocol depends on your scenario and needs.

> → Tip
>
> If you use Microsoft Entra ID as your corporate identity provider with SAML, you can additionally enable OIDC for your applications. Instead of looking under *Enterprise Applications* for the SAML configuration,

find the OIDC configuration for Entra ID under *App Registrations* and search for the application ID. Configure the required redirect URIs.

For more information, see the documentation for Microsoft Entra ID.

1.7.16.4.1 Create Corporate IdP in Administration Console

Create a new corporate identity provider (IdP) and customize it or copy the configuration from an existing one.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Context

When you create a new corporate IdP in the administration console for SAP Cloud Identity Services you can also change the default SAML 2.0 Compliant type choice offered to you to Single Sign-On (SAML 2.0), Microsoft ADFS / Entra ID (SAML 2.0) or OpenID Connect Compliant types.

You can also copy the settings from an IdP that is already existing in your tenant to the new corporate IdP. For example, you can have separate SAML 2.0 and OpenID Connect IdP trust configurations for one and the same corporate IdP. Thus, you can migrate your applications from one protocol to another by switching application by application to the new trust.

→ Remember

If you are copying the settings from one type of corporate IdP to another, all settings are copied apart from the ones that are protocol-specific (SAML 2.0 or OpenID Connect).

After copying the setting, configure the trust manually for the newly created IdP, and adjust the key value pairs in the *Enriched Token Claims* section.

To create a new corporate IdP, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Choose the *Create* button on the left-hand panel.

4. Provide the following information in the dialog box:

Fields	Notes
Display Name	Required. The display name of the identity provider.
Identity Provider Type	Optional. You can choose one of the following options: • SAML 2.0 Compliant • SAP Single Sign-On (SAML 2.0) • Microsoft ADFS / Entra ID (SAML 2.0) **⚠ Caution** For this type, the digest algorithm of the corporate identity provider must be *SHA-256*. For more information, see 2. Configure Trust on Identity Authentication Side in Configure Trust with Corporate Identity Provider [page 2560]. • OpenID Connect Compliant
Copy Settings from Identity Provider	Optional. You can create a brand new corporate IdP or copy the configurations from an already existing one. Possible options: • Don't copy (default) - create a corporate IdP and after that configure it. • Choose from a list with all corporate IdPs that are created in the admin console - the new corporate IdP gets all configuration settings apart from the protocol-specific ones (SAML or OpenID Connect) of the selected corporate IdP.

5. Save your changes.

Results

Once the identity provider has been created, the system displays the message `Identity provider <name of identity provider> created`.

The newly created identity provider appears on the list on the left. It is selected and you can proceed with its configuration.

1.7.16.4.2 Configure Trust with SAML 2.0 Corporate Identity Provider

This document is intended to help you configure trust with a SAML 2.0 corporate identity provider. In this scenario Identity Authentication acts as a proxy to delegate the authentication to the SAML 2.0 corporate identity provider.

Context

Identity Authentication can use a SAML 2.0 identity provider as an external authenticating authority. Identity Authentication thus acts as a proxy to delegate authentication to the external corporate identity provider. The requests for authentication sent by a service provider will be forwarded to the corporate identity provider.

As an identity provider proxy, Identity Authentication will act as an SAML 2.0 identity provider to the service provider, and as an SAML 2.0 service provider to the corporate identity provider. Once a user is authenticated at the corporate identity provider, successive authentication requests from service providers, which use the same corporate identity provider will not be forwarded to it as long as the session at Identity Authentication is active. Identity Authentication will issue assertions based on the user data received during the first authentication.

> ⓘ Note
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

To use Identity Authentication as a proxy to delegate authentication to an external corporate identity provider you have to configure trust with that corporate identity provider.

> → Tip
>
> If you want to change one corporate identity provider with another, for example move from a SAML identity provider to an OpenID Connect (OIDC) one, it's helpful to know the applications that the corporate identity provider uses. To see the applications that have established trust with a specific corporate identity provider, sign in to the administration console and go to *Identity Providers* > *Corporate Identity Providers* > *identity provider from the list* > *Trusting Applications*.

To configure trust with the corporate identity provider, follow the procedures below:

1. Configure Trust on the Corporate Identity Provider Side

Set up trust with Identity Authentication as a service provider.

Prerequisites

You have the SAML 2.0 metadata of Identity Authentication. For more information how to download the metadata, see Tenant SAML 2.0 Configurations [page 2103].

Context

Procedure

1. Register Identity Authentication as a service provider at the corporate identity provider.

   → Remember

   If you want to use IdP-initiated single sign-on (SSO) from your corporate identity provider, you have to add the parameter `sp=<sp_name>` to the assertion consumer service (ACS) endpoint configured on your corporate identity provider side for Identity Authentication.

   ✤ Example

   https://<the current ACS endpoint URL>?sp=<sp_name>>

   `sp` is the name of the SAML 2 service provider for which SSO is performed.

   To see how to download the SAML 2.0 metadata of Identity Authentication read Tenant SAML 2.0 Configurations [page 2103].

2. **Optional:** Download the corporate identity provider SAML 2.0 metadata.

   You need the corporate SAML 2.0 metadata for the setup of the trust on Identity Authentication. Optionally, you can make the configurations manually.

2. Configure Trust on Identity Authentication Side

Set up trust with a corporate identity provider in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have registered Identity Authentication as service provider at the corporate identity provider.
- You have the corporate identity provider SAML 2.0 metadata.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Under *SAML 2.0*, choose *SAML 2.0 Configuration*.
5. Upload the corporate identity provider metadata XML file, use metadata URL, or manually enter the communication settings negotiated between Identity Authentication and the identity provider.

   > ⓘ Note
   >
   > Use a file with an extension `.xml`.

   When the identity provider metadata is uploaded, or the metadata URL is used, the fields are populated automatically with the parsed data from the XML file. The minimum configuration is to complete the *Name* field, add at least one single sign-on endpoint, and provide a signing certificate.

   You can add up to two signing certificates. Both signing certificates are accepted according to the certificate validity.

Field	Description
Choose: • Metadata File • Metadata URL	• The metadata XML file of the identity provider. • The URL with identity provider metadata. > ⚠ Restriction > The metadata URL must not contain query parameter.

Field	Description
Name	The entity ID of the identity provider.
Single Sign-On Endpoint URL	The URL of the identity provider single sign-on endpoint that receives authentication requests. → Remember Use *HTTP-Redirect* as default binding if you have a link which takes the users to a specific application with a specific corporate identity provider when `Identity Authentication` acts as proxy to multiple corporate identity providers (IdP), and the identity providers are more than one. For more information, see Create URLs to Access Applications with Specific Identity Providers [page 2605].
Single Logout Endpoint URL	The URL of the identity provider's single logout endpoint that receives logout messages.
Binding	The SAML-specified HTTP binding used by the identity provider showing how the various SAML protocol messages can be carried over underlying transport protocols.
Signing Certificate	A base64-encoded certificate used by the service provider to sign digitally SAML protocol messages sent to Identity Authentication. Use the *Add* button to add a second signing certificate. ⓘ Note If you have two certificates, you can choose a default one, to mark your primary certificate.

6. **Optional:** Choose the digest algorithm for signing outgoing messages from the dropdown list in the *Algorithm* section. You have the following options:

   - *SHA-1*
   - *SHA-256* - the default option

     → Remember

     The algorithm must be *SHA-256* if the Identity provider type is set at *Microsoft ADFS / Entra ID*.
   - *SHA-512*

7. **Optional:** Sign SAML 2.0 authentication requests. You have the following options:

Option	Notes
Sign authentication requests	Enabled - default configuration
Sign single logout messages	Enabled - default configuration

8. **Optional:** Enable or disable the *Include scoping* attribute to include or exclude the Scoping element in the SAML 2.0 request.

   > → Remember
   >
   > The default setting for the *Include scoping* is enabled. The Scoping element sent in the SAML 2.0 request is 1.
   >
   > If the identity provider type is set at *Microsoft ADFS / Entra ID* the default setting for the *Include scoping* is disabled and the Scoping element is not sent in the SAML 2.0 request.

9. Save your selection.

   Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Next Steps

- Select the configured identity provider as the authenticating identity provider for the application. For more information, see Choose Default Identity Provider for an Application [page 2067].
- (Optional) Configure the Name ID Format Attribute Sent to the SAML 2.0 Corporate IdP [page 2577]

Related Information

Edit Administrator Authorizations [page 2309]
Configure IdP-Initiated SSO [page 2201]
Choose Identity Provider Type [page 2602]

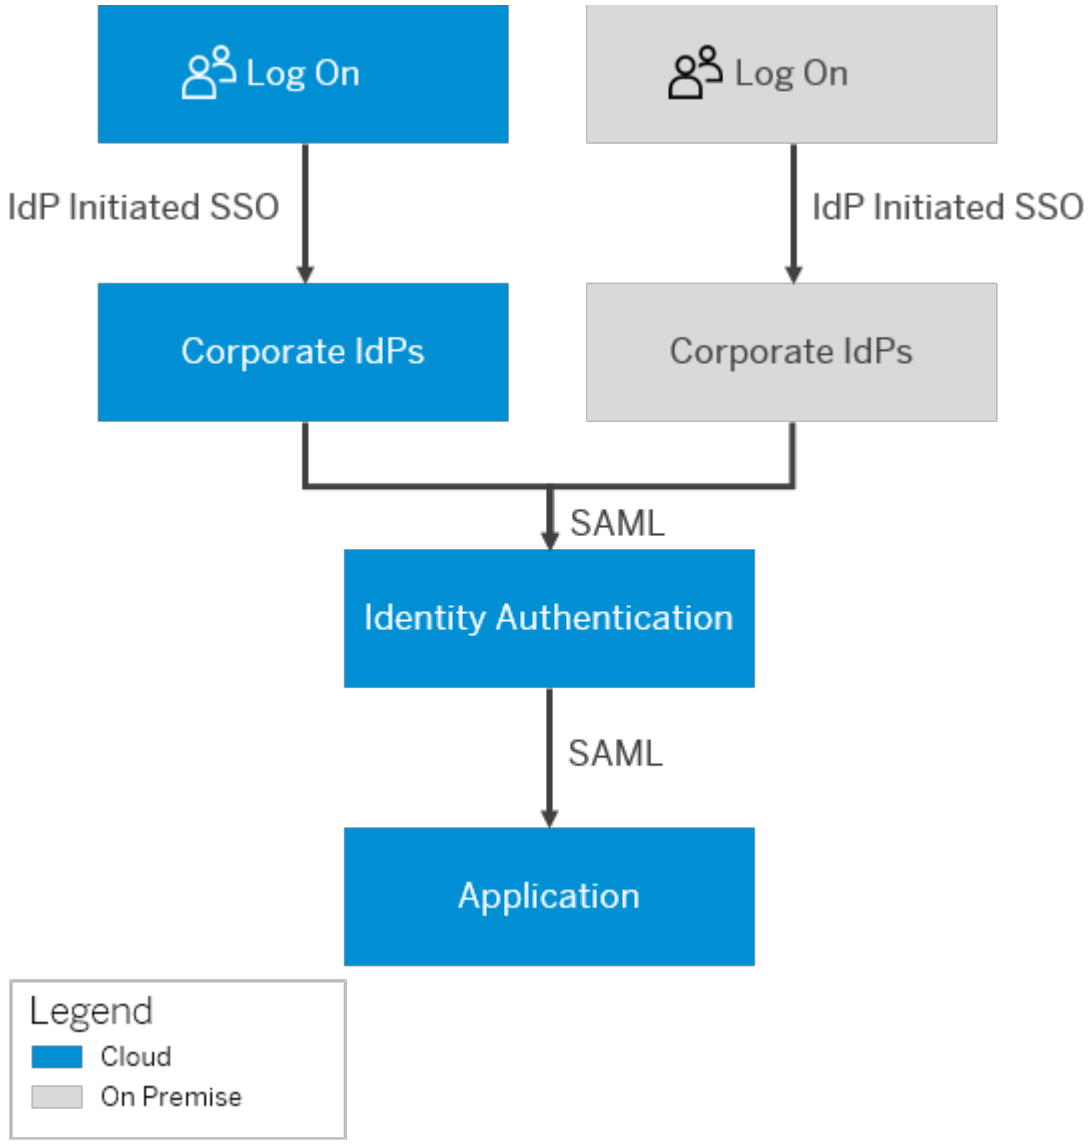
1.7.16.4.2.1 Configure IdP-Initiated SSO with Corporate Identity Providers

This document shows you how to configure identity provider (IdP) initiated single sign-on (SSO) with corporate identity providers.

This use case is suitable for customers and partners who need to provide access to a cloud application for their employees via their corporate identity providers. When Identity Authentication acts as proxy to multiple identity providers you can allow the partner users to login via their corporate identity providers.

In this scenario the authentication starts at the corporate identity provider (IdP), with Identity Authentication being in the role of an identity provider proxy. As such, Identity Authentication will act as an SAML 2.0 identity provider to the service provider, and as an SAML 2.0 service provider to the corporate identity provider or providers. Once a user is authenticated at the corporate identity provider, successive authentication requests from the service provider, which use the same corporate identity provider will not be forwarded to it while the session at Identity Authentication is active. Identity Authentication will issue assertions based on the user data received during the first authentication.

This scenario also supports authentication with more than one corporate identity provider.



Configuration Steps

For this scenario, the configurations are made by users with different roles in different systems.

Configuration and Roles

Role	System to be configured	What has to be configured	More Information
Application administrator	Consumer application	Trust	Configure Identity Authentication as a Trusted Identity Provider for the Application [page 2566]

Role	System to be configured	What has to be configured	More Information
Tenant administrator	Tenant of Identity Authentication	• Authenticating identity providers • (Optional) Configure the *Trust Corporate Identity Providers* feature in the administration console.	• Configure Identity Authentication To Trust the Corporate Identity Provider [page 2567] • Enable SSO with Corporate Identity Providers [page 2087]
Tenant administrator	Tenant of Identity Authentication	(Optional) User attributes and access for users. Enable the *Identity Federation* options in the administration console.	(Optional) Configure Additional Settings in Identity Authentication [page 2571]
Corporate IdP administrator	Corporate IdP	• Trust • Assertion consumer service endpoint	Configure the Corporate Identity Provider [page 2574]

For more information about the configuration steps, follow the links in the table or see the sections below.

Prerequisites

The IDP-Initiated SSO option in the tenant of Identity Authentication must be enabled.

> ⓘ Note
>
> IDP-Initiated SSO is enabled by default in Identity Authentication. For more information about how the tenant administrator can enable or disable this option, see Configure IdP-Initiated SSO [page 2201].

1.7.16.4.2.1.1 Configure Identity Authentication as a Trusted Identity Provider for the Application

Context

The following configuration is made by the administrator of the application.

As an administrator of the application, you have to configure Identity Authentication as a trusted identity provider for the application.

> ⓘ Note
>
> To do this, you will need the SAML 2.0 metadata of Identity Authentication. To receive the metadata, contact the tenant administrator of Identity Authentication.

Next Steps

Send the metadata of the service provider to the administrator of Identity Authentication. This is required for setting up the trust on the Identity Authentication provider side. For more information about how to set up th etrust, see Configure SAML 2.0 Service Provider [page 1941].

1.7.16.4.2.1.2 Configure Identity Authentication To Trust the Corporate Identity Provider

Context

In the scenario where Identity Authentication acts as an identity provider proxy, it is in the role of an identity provider for the application, and a service provider for the corporate identity provider. You should configure trusts with the service provider and the corporate identity provider.

The following configuration is made by the tenant administrator of Identity Authentication.

Procedure

1. Configure trust with the service provider via the administration console. For more information, see Configure SAML 2.0 Service Provider [page 1941].

   For this procedure, you will need the metadata from the service provider. If you do not have this, contact the administrator of the application.

   The service provider metadata that is used to configure the trust must contain the default assertion consumer service (ACS) endpoint that can process unsolicited SAML responses.

   > → Remember
   >
   > With SAP BTP, the endpoint is the URL of the application's protected page.
   >
   > If your scenario includes the configuration of the *Trust Corporate Identity Providers* option in the administration console, the service provider metadata that is used to configure the trust must contain also the assertion consumer (ACS) endpoint with the URL of the application's protected page and the index.

> ### Sample Code
>
> ```
> <ns3:AssertionConsumerService index="1" isDefault="false"
> Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
> Location="https://<application URL>/protected.jsp"
> />
> ```

2. Configure a trust with the corporate identity provider. For more information, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560].

   For this procedure, you will need the metadata from the corporate identity provider. If you do not have this, contact the administrator of the corporate identity provider.

3. Select identity provider. You have the following options:

   - If your scenario includes more than one corporate identity provider, configure the *Trust Corporate Identity Providers* feature in the administration console. For more information, see Enable SSO with Corporate Identity Providers [page 2087].
   - If your scenario includes only one corporate identity provider, set the configured identity provider as the authenticating identity provider for the application. For more information, see Choose Default Identity Provider for an Application [page 2067].

Next Steps

1. Send the `Entity ID` of the service provider to the administrator of the corporate identity provider. The administrator needs this information for the consumer assertion endpoint configuration.

   > ### → Tip
   >
   > The `Entity ID` of the service provider is in the administration console in *Applications* > *<application_name>* > *Trust* > *SAML 2.0 Configuration* > *Name*.

   > ### → Remember
   >
   > If your scenario includes the configuration of the *Trust Corporate Identity Providers* option in the administration console, send also the index of the ACS endpoint of the application's protected page. The administrator needs this information for the consumer assertion endpoint configuration.

2. Send the metadata of the tenant of Identity Authentication to the administrator of the service provider and the administrator of the corporate identity provider. They need the metadata for the trust configurations of the systems. For more information about how to download the tenant metadata, see Tenant SAML 2.0 Configurations [page 2103].

1.7.16.4.2.1.3 Enable SSO with Corporate Identity Providers

Tenant administrators can enable IdP-initiated Single Sign-On (SSO) from one, more than one or all configured corporate identity providers (IdPs).

Prerequisites

- You are assigned the *Manage Applications* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have more than one corporate identity provider, which is configured in the administration console. For more information on how to configure a corporate identity provider, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560] or Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
- (For SAML 2.0 applications) You have added the assertion consumer (ACS) endpoint with the URL of the application's protected page, and the index, in the metadata of that application. The ACS endpoint that you added should look like the following example:

  Sample Code

  ```
  <ns3:AssertionConsumerService index="1" isDefault="false"
  Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Location="https://
  <application URL>/protected.jsp"
  />
  ```

  For more information how to configure your ACS endpoint in the administration for Identity Authentication, see Configure SAML 2.0 Service Provider [page 1941].

Context

Applications can be configured to trust one, more than one, or all corporate identity providers configured in the administration console when identity provider (IdP) initiated Single Sign-On (SSO) is used. The user accesses the application via a URL provided by the corporate identity provider.

To enable IdP-initiated SSO with corporate identity providers configured in the administration console for SAP Cloud Identity Services follow the following procedure:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under the *Conditional Authentication* section, choose the *Trust Corporate Identity Providers* list item.
6.

Option	Notes
Enable the slider to allow SSO with all configured corporate identity providers.	All corporate IdPs are allowed for sign-in. By default this option is disabled. If enabled, all configured corporate IdPs are hidden, and you can't select a specific IdP from the list.
Select a specific corporate IdP from the list.	→ Remember The slider on the top-right corner of the screen must be disabled. If enabled, all configured corporate IdPs are hidden

Once the application has been updated, the system displays the message `Application <name of application> updated`.

Results

The application trusts the selected corporate identity providers that are configured in the administration console for SAP Cloud Identity Services.

Related Information

Configure IdP-Initiated SSO with Corporate Identity Providers [page 2564]

1.7.16.4.2.1.4 (Optional) Configure Additional Settings in Identity Authentication

Context

The following configurations are made by the tenant administrator of Identity Authentication.

Follow the procedures in this document if you want to:

- **Restrict Access to Users in Identity Authentication User Store**
- **Restrict Access to Users in Certain Groups**
- **Send Specific Assertion and Name ID Attributes to the Application**
- **Apply Application Configurations**

Send Specific Assertion and Name ID Attributes to the Application

Context

When the *Use Identity Authentication user store* option is disabled, Identity Authentication sends to the application the same attributes it has received from the corporate identity provider.

When the *Use Identity Authentication user store* is enabled, Identity Authentication checks if a user with the respective unique identifier, written in the NameID attribute in the assertion coming from the corporate identity provider, exists in the user store of Identity Authentication. The following options exist:

- If the user exists, Identity Authentication issues a new nameID, assertion and default attributes, configured for the application.
- If the user does not exist in the user store of Identity Authentication, the application receives the nameID from the corporate IdP assertion and the attributes according to the application configuration.

This configuration can be used if you want the application to receive assertions and name ID attributes that are different from those sent by the corporate identity provider.

If you want the application to receive assertions and name ID attributes that are different from those sent by the corporate identity provider, do the following: Configuring User Attributes from the Identity Directory [page 1973] and Configure the Subject Name Identifier Sent to the Application [page 1988].

Procedure

1. Switch on the *Use Identity Authentication user store* option in the administration console. For more information, see Configure Identity Federation [page 2614].

2. Configure the user attributes and Name ID attribute sent to the application. For more information, see:
    - Configuring User Attributes from the Identity Directory [page 1973]
    - Configure the Subject Name Identifier Sent to the Application [page 1988]

Results

The application will receive in the assertion the attributes and name ID attribute that you have configured in Identity Authentication. They will be different from those that the corporate identity provider sent to Identity Authentication.

Restrict Access to Users in Identity Authentication User Store

Context

This configuration allows you to restrict access to the application to users who are in the Identity Authentication user store. Users who are not in the user store of Identity Authentication will not be able to access the application.

Procedure

1. Provision, or import the users that you will grant access to the application to via a CSV file import.

    For more information about how to import users in Identity Authentication, see Import or Update Users for a Specific Application [page 2348].
2. Switch on the *Use Identity Authentication user store* and *Allow Identity Authentication users only* options under *Identity Federation* in the administration console. For more information, see Configure Identity Federation [page 2614].

Results

Only users that are in the user store of Identity Authentication will be able to access the application. If a user is not part of the user store of Identity Authentication, this user receives the following message: `Sorry, but you are currently not authorized for access.`

The settings in the application configuration for assertion attributes and name ID attribute will be used for issuing the assertion. For more information, see Configuring User Attributes from the Identity Directory [page 1973]and Configure the Subject Name Identifier Sent to the Application [page 1988].

Restrict Access to Users in Certain Groups

Context

This configuration allows you to restrict the access to the application only to users who belong to certain groups. This option is suitable for scenarios with more than one corporate identity providers. The tenant administrator assigns different groups to different identity providers and users, and can thus specify that certain users come from specific identity providers by assigning the same groups to them. Identity Authentication can thus check if the users are authenticated by the identity provider that they belong to.

Procedure

1. Make sure that the required groups are created in the administration console of Identity Authentication. For more information, see Create a Group [page 2398].
2. Provision, or import the users that you will grant access to the application via a CSV file import.

   > ⚠ Caution
   >
   > The groups in the *Groups* column in your CSV file must match the groups that you created via the administration console.

   For more information about how to import users in Identity Authentication, see Import or Update Users for a Specific Application [page 2348].
3. Switch on the *Use Identity Authentication user store* and *Allow Identity Authentication users only* options under *Identity Federation* in the administration console. For more information, see Configure Identity Federation [page 2614].
4. Assign groups to the corporate identity provider. For more information, see Configure Identity Federation [page 2614].

Results

Only the members of these groups will be authorized to access applications after successful authentication. If a user is not part of the groups, this user receives the following message: `Sorry, but you are currently not authorized for access.`

Apply Application Configurations

Prerequisites

Context

This configuration allows you to apply the following application configurations, when Identity Authentication is used as a proxy.

Procedure

1. Provision, or import the users that you will grant access to the application to via a CSV file import.

   For more information about how to import users in Identity Authentication, see Import or Update Users for a Specific Application [page 2348].
2. Switch on the *Use Identity Authentication user store* and *Allow Identity Authentication users only* options under *Identity Federation* in the administration console. For more information, see Configure Identity Federation [page 2614].
3. Switch on the *Apply Application Configurations* option. For more information, see Configure Identity Federation [page 2614].

Results

The application configuration will be taken into consideration, when the users are authenticated by the corporate IdP.

1.7.16.4.2.1.5 Configure the Corporate Identity Provider

Context

The following configuration is made by the administrator of the corporate identity provider.

Procedure

1. Register Identity Authentication as a service provider.

   > ⓘ Note
   >
   > To do this, you will need the SAML 2.0 metadata of Identity Authentication. If you do not have this, contact the tenant administrator of Identity Authentication.

> → Tip
>
> For more information about how to register Identity Authentication as a service provider, consult the corporate identity provider documentation. If the corporate identity provider is also a tenant of Identity Authentication, see Configure Trust [page 1941].

2. Add the `sp=<sp_name>` parameter, and the index of the application's assertion consumer service (ACS) endpoint URL, if provided. Replace the `sp_name` with the `Entity ID` of the service provider. This parameter is needed for Identity Authentication to know which service provider to redirect the user to after successful authentication.

   > → Tip
   >
   > The ACS endpoint URL should have the following format: `https://<the current ACS endpoint URL>?sp=<sp_name>&index=<index_number>`. Request the `Entity ID` of the service provider, and the index of the application's protected page from the tenant administrator of Identity Authentication.
   >
   > The index is required when the application has multiple ACS endpoint URLs and the default one is not the one that should be used.

Results

Once the trust is configured, the user can access the application via the link sent by the corporate identity provider administrator. For more information about how to configure the link for the IdP-initiated SSO scenario, consult the corporate identity provider documentation.

> → Tip
>
> If your corporate identity provider is Identity Authentication, the link for IdP-Initiated SSO follows the pattern: https://<tenant_ID>.accounts.ondemand.com/saml2/idp/sso?sp=<sp_name>[&RelayState=<sp_specific_value>&index=<index_number>]. In this use case, replace the `sp_name` with the `Entity ID` of the tenant of Identity Authentication acting as the service provider. The `RelayState` is not mandatory and can be skipped. If your scenario includes only one corporate identity provider, the `index` parameter is not mandatory and also can be skipped. If your scenario includes more than one corporate identity provider, and the *Trust Corporate Identity Providers* feature in the administration console is enabled, the `index` is used to determine the ACS endpoint which could process unsolicited SAML responses. For more information about the configuration, see Configure IdP-Initiated SSO [page 2201].

Next Steps

Send the metadata of the corporate identity provider to the administrator of Identity Authentication. This will be needed for setting up the trust.

1.7.16.4.2.2 Enrich Assertion Attributes Coming from Corporate IdP

Tenant administrator can modify the assertion attributes received from the corporate identity provider (IdP) before they are sent to the application (service provider) that uses the corporate IdP for authentication.

Context

The attributes received from the corporate IdP by Identity Authentication are modified and thus sent to the application in the assertion.

The attributes are also put in the `id_token` if the application is OpenID connect. For more information, see Configuring OpenID Connect (OIDC) [page 2636].

For both the SAML 2.0 and OpenID Connect applications, you can configure attributes with:

- dynamic values - The assertion attributes can take up to two dynamic values. They are added into the assertions in the following pattern: `<prefix> ${<received_attribute>} <suffix>`. You can also use multivalue attributes.

  > ⚠ Restriction
  >
  > The combination of two multivalue attributes is not allowed. The assertion attributes can take two single value attributes or a single value and a multivalue attribute.

- static values

> ⚠ Restriction
>
> The `sap_licenses` attribute is not supported for the enrich assertion attributes scenario.

You can add up to 30 attributes per corporate IdP.

Identity Federation

When the application uses corporate IdP for authentication, the assertion attributes enriched in the administration console for SAP Cloud Identity Services are taken into consideration and sent to the application in the modified form, if the *Use Identity Authentication user store* option under *Identity Federation* is disabled.

If *Identity Federation* is configured, use the modified attributes in the *Default Attributes* section for the applications that use the corporate IdP for authentication. For more information, see Configuring Attributes Based on Flexible Expressions [page 1979].

> ⓘ Note
>
> You can also overwrite the `Subject Name Identifier` via the *Enrich Assertion Attributes* option. Identity Authentication sends the modified attribute to the application as `NameID` in the SAML 2.0 assertions, and as `sub` in the OpenID Connect tokens.
>
> When overwriting the `Subject Name Identifier` you can use the `${NameID}` variable to include the `NameID` received from the Identity Provider. You can't use the `${NameID}` variable for any other attributes.
>
> The `Subject Name Identifier` must be added in the following pattern:

Attribute	Value
NameID	`<prefix>${NameID}<suffix>`

To modify the assertion attributes coming from the corporate IdP, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Under *Trust*, choose the *Enriched Assertion Attributes* list item.
5. Add the attributes as received from the corporate IdP with the new values to be sent to the application.
6. Save your configuration.

   If the operation is successful, you receive the message `Identity provider "<name of identity provider>" updated`.

1.7.16.4.2.3 (Optional) Configure the Name ID Format Attribute Sent to the SAML 2.0 Corporate IdP

Context

When Identity Authentication uses a SAML 2.0 identity provider (IdP) as an external authenticating authority it acts as a proxy to delegate authentication to that external corporate identity provider. As an identity provider proxy, Identity Authentication acts as a SAML 2.0 identity provider to the service provider, and as a SAML 2.0 service provider to the corporate identity provider. The requests for authentication sent by the service provider are forwarded by Identity Authentication to the corporate identity provider.

In this scenario, the tenant administrator can configure the name ID format that is sent to the corporate identity provider. The name ID format is used in the `Format` attribute of the `NameID` element that Identity Authentication sends to the corporate identity provider with the SAML 2.0 authentication request.

The tenant administrator can also configure if and how the `AllowCreate` attribute is sent to the corporate identity provider.

> → Remember
>
> To use Identity Authentication as a proxy to delegate authentication to an external corporate identity provider you have to configure trust with that corporate identity provider. For more information, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560].

To set the name ID format to be sent to the corporate identity provider, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].
4. Under *SAML 2.0*, choose *Name ID Policy*.
5. Select the name ID format from the following:
   - *None* - Name ID format is not sent. Corporate identity provider decides which attribute to use.
   - *Default* - The name ID format received from the application is sent.
   - *Unspecified* - The name ID format `urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified` is always sent.
   - *Email* - The name ID format `urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress` is always sent.
6. Select the AllowCreate configuration from the following:
   - *None* - `AllowCreate` attribute sent by the Service Provider is ignored.
   - *Default* - `AllowCreate` attribute sent by the Service Provider is forwarded to the Corporate IdP.
   - *True* - `AllowCreate` attribute with value "true" is always forwarded to the Corporate IdP.
   - *False* - `AllowCreate` attribute with value "false" is always forwarded to the Corporate IdP.
7. Save your selection.

   Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Choose Identity Provider Type [page 2602]

1.7.16.4.3 Configure Trust with OpenID Connect Corporate Identity Provider

This document is intended to help you configure trust with an OpenID Connect (OIDC) corporate identity provider. In this scenario, Identity Authentication acts as a proxy to delegate the authentication to an OIDC-compliant corporate identity provider.

Context

Identity Authentication can use OIDC-compliant identity providers as external authenticating authorities. The service acts as a proxy to delegate authentication to the external corporate identity provider. The requests for authentication sent by the relying party are forwarded to the corporate identity provider.

As an identity provider proxy, Identity Authentication acts as an OpenID identity provider to the relying party, and as a relying party to the corporate identity provider. Once a user is authenticated at the corporate identity provider, successive authentication requests from relying parties, which use the same corporate identity provider aren't forwarded to it as long as the session at Identity Authentication is active. Identity Authentication issues JSON Web Tokens (JWTs) based on the user data received during the first authentication.

To use Identity Authentication as a proxy to delegate authentication to an external OpenID Connect corporate identity provider, configure trust with that corporate identity provider.

> → Tip
>
> If you want to change one corporate identity provider with another, for example move from a SAML identity provider to an OpenID Connect (OIDC) one, it's helpful to know the applications that the corporate identity provider uses. To see the applications that have established trust with a specific corporate identity provider, sign in to the administration console and go to *Identity Providers* > *Corporate Identity Providers* > *identity provider from the list* > *Trusting Applications*.

To configure trust with the corporate identity provider, use the following procedures:

1. Configure the Corporate Identity Provider Side

Configuration of Identity Authentication as a client in the corporate identity provider establishes the necessary trust and connectivity for delegating authentication through OpenID Connect. This step is required to enable secure user authentication with the corporate identity provider.

Prerequisites

- You have registered Identity Authentication as an application of the corporate identity provider.

> ### Note
>
> The corporate identity provider complies with OpenID Connect Discovery .

- You have created a client secret.

  > ### Note
  >
  > Use the client credentials of the application's registration for Client ID and Client Secret. Use corporate identity provider tenant as Issuer. You can retrieve the information by calling the discovery endpoint of the corporate identity provider:
  >
  > ```
  > https://<OpenID-Connect-IdP>/.well-known/openid-configuration
  > ```

- (For the authorization code flow) - You have configured the callback endpoint of the Identity Authentication tenant as `Redirect URI`

  ```
  https://<Cloud Identity Services domain>/oauth2/callback
  ```

  > ### Note
  >
  > The domain part has the following pattern:
  >
  > `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
  >
  > *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

> ### Note
>
> Use the *OIDC Callback URL* button to copy the callback URL of the Identity Authentication tenant.

Context

The information retrieved from `.well-known/openid-configuration` endpoint can contain:

Attribute		Notes
`issuer`		Required. Must be a valid URI. **Note** If you already have a corporate identity provider configuration with this issuer, configure your corporate identity provider to include an audience claim using the client ID, so the correct configuration can be identified. See also 3718653.
`jwks_uri`		Required. Must be a valid HTTPS URI.
	`id_token_signing_alg_values_supported`	Required. The JSON array must list the JWS signing algorithms (alg values) the OpenID provider supports for encoding ID token claims in a JWT.
	`response_types_supported`	Required. The JSON array lists the supported OAuth 2.0 `response_type` values.
	`subject_types_supported`	Required. The JSON array lists the subject identifier types this OpenID provider supports.
`authorization_endpoint`		Optional. If present it must be a valid HTTPS URI.
`end_session_endpoint`		Optional. If present it must be a valid HTTPS URI. **→ Remember** If the `end_session_endpoint` isn't supported by the OpenID Connect corporate identity provider, the corporate identity provider can't participate in single logout flows.
`token_endpoint`		Optional. If present it must be a valid HTTPS URI. **Note** If the `token_endpoint` isn't supported, it can't participate in browser-based SSO flows. JWT Bearer flow is still possible.

Attribute	Notes
`userinfo_endpoint`	Optional. If present it must be a valid HTTPS URI.
`grant_types_supported`	Optional. → Remember If `grant_types_supported` is provided in the metadata, it must contain `authorization_code`, which means that the OpenID Connect provider must support the authorization code flow.

2. Configure the Identity Authentication Side

Configure the corporate identity provider in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have registered Identity Authentication as an application at the corporate identity provider.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.
4. Under *Provider Configuration* enter the following information for the corporate identity provider:

Provider Configuration	Notes
Discovery URL	Required. Issuer or metadata URL of the corporate identity provider.

Provider Configuration	Notes
Name	Required. Enter a text string. Use a value that can serve as a URL parameter, such as a URI. These values don't need to be escaped. There is no default value. If you load the discovery URL before you enter a name, the system uses the name you chose when you created this identity provider configuration. For more information, see Create Corporate IdP in Administration Console [page 2558].
Metadata Refresh Interval	Refreshes the OpenID Connect metadata of the corporate identity provider automatically if it's older than the selected interval and there are logons which forward the request to the corporate identity provider. Optional. Choose from: • 24 hours (default choice) • 12 hours

5. Under *Client Authentication* enter the following information for the corporate identity provider:

Client Authentication Method	Optional. Choose from: • Client secret in body (default choice) • Client secret in authorization header • Private key JWT • Client assertion in body → Tip If possible, choose **`Private key JWT`** or **`Client assertion in body`**. → Recommendation If you connect Microsoft EntraID, use **`Client assertion in body`** and configure the trust in EntraID. This configuration enables an automatic trust update, because EntraID fetches the keys for signature validation automatically. Use the read-only *JWT Issuer* and *JWT Audience* values displayed below to complete the certificate credential configuration in Entra ID.
Client ID	Required. The Client ID of the application on the corporate identity provider side.

Client Secret	Required when *Client Authentication Method* is **`Client secret in body`** or **`Client secret in authorization header`**. The Client Secret of the application on the corporate identity provider side.
Audience	Required when *Client Authentication Method* is **`Private key JWT`**. The audience value that SAP Cloud Identity Services includes in the `aud` claim of the JWT client assertion sent to the corporate identity provider. Choose the value that the corporate identity provider expects: • *Issuer (default)*: the audience is set to the issuer identifier of the corporate identity provider, as retrieved from its OpenID Connect discovery document. • *Token endpoint*: the audience is set to the token endpoint URL of the corporate identity provider. Consult the documentation of your corporate identity provider to determine the correct value. For example, Microsoft Entra ID requires *Token endpoint*.
JWT Subject	Required when *Client Authentication Method* is **`Client assertion in body`**. The subject of the JWT client assertion sent to the corporate identity provider. By default, the system pre-fills this field with the name of the corporate identity provider. If the name is not available, the display name is used.
JWT Issuer	Read-only. Applies when *Client Authentication Method* is **`Client assertion in body`**. The issuer value that Identity Authentication includes in the JWT client assertion. Enter this value in the configuration of the corporate identity provider, for example when configuring certificate credentials in Microsoft Entra ID.
JWT Audience	Read-only. Applies when *Client Authentication Method* is **`Client assertion in body`**. The audience value that Identity Authentication includes in the JWT client assertion. Enter this value in the configuration of the corporate identity provider. **Note** The JWT Issuer and JWT Audience values are always identical.

6. **Optional:** If needed for your scenario, choose from the *Advanced Settings*.

   For more information, see:

   - Configure PKCE for Corporate Identity Providers [page 2588]
   - Enforce Nonces for Corporate Identity Providers [page 2589]

- Disable ID Token Hints for Corporate Identity Providers [page 2590]

7. **Optional:** View the OpenID Connect issuer and endpoints under the *Endpoints* section.

   The *Endpoints* section is read-only. The *Issuer* shown here is the issuer of the corporate identity provider retrieved from its metadata, not the Identity Authentication Issuer used in client assertions.

8. **Optional:** Add additional scopes if needed.

   You can have up to 20 scopes. The `openid` scope is added by default. Each scope can have a length of up to 99 characters.

   > → Tip
   >
   > If you're using Microsoft Entra ID as corporate identity provider, the recommended claims are:
   > - openid
   > - email
   > - profile

9. **Optional:** Choose the *Validate* button to check the configuration.

   An authorization code flow is run against the corporate identity provider. The configuration is validated in a new tab where additional information about the authorization code, the token with all the claims and scopes, and the token verification is provided.

   > → Tip
   >
   > When SAP Cloud Identity Services works with an OIDC corporate identity provider, we expect a response time within 10 seconds. The response time can be a problem for on-premise identity providers, which don't have defined service level agreements like cloud-based identity providers. To use this configuration, you must ensure that the corporate identity provider can respond within this timeframe. When the corporate identity provider doesn't respond quickly enough, SAP Cloud Identity Services presents the following error message:
   >
   > `OpenID provider cannot process the request because the configuration is incorrect. Please contact your system administrator.`

10. Save your configuration.

    Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Next Steps

- Select the configured identity provider as the authenticating identity provider for the application. For more information, see Choose Default Identity Provider for an Application [page 2067].
- (Optional) Configure the Subject Name Identifier Sent to the OpenID Connect Corporate IdP [page 2587]

Related Information

Edit Administrator Authorizations [page 2309]

Logging OpenID Connect (OIDC) Tokens [page 2980]

Microsoft identity platform application authentication certificate credentials

1.7.16.4.3.1 Enrich Token Claims Coming from Corporate IdP

Tenant administrator can modify the token claims received from the corporate identity provider (IdP) before they are sent to the application that uses the corporate IdP for authentication.

Context

The claims are put in the JSON Web Tokens (JWTs) for the OpenID Connect application. For more information, see Configuring OpenID Connect (OIDC) [page 2636].

For the OpenID Connect applications, you can configure claims with:

- dynamic values - The claims can take up to two dynamic values. They are added into the tokens in the following pattern: `<prefix> ${<received_attribute>} <suffix>`. You can use also multivalue claims.

  > ⚠ Restriction
  >
  > The combination of two multivalue claims is not allowed.

- static values

You can add up to 30 claims per corporate IdP.

SAP Cloud Identity Services supports nested attributes. You can use up to five layers of nesting. For example, `${"kubernetes.io".serviceaccount.name}`.

Identity Federation

If *Use Identity Authentication user store* under *Identity Federation* is disabled, modify the token claims received from the corporate identity provider (IdP). The claims enriched in the administration console for SAP Cloud Identity Services are thus taken into consideration and sent to the application in the modified form. The application specific settings, the claims in the *Default Attributes* section, are ignored.

If *Use Identity Authentication user store* under *Identity Federation* is enabled, use the modified claims in the *Default Attributes* section for the applications that use the corporate IdP for authentication. For more information, see Configuring Attributes Based on Flexible Expressions [page 1979].

> ⓘ Note
>
> You can also overwrite the `Subject Name Identifier` via the Enriched Token Claims option. Identity Authentication sends the modified claim to the application as `subject` in the OpenID Connect tokens.
>
> The `Subject Name Identifier` must be added in the following pattern:

Claim	Value
NameID	`<prefix> ${<NameID>} <suffix>`

To modify the claims coming from the corporate IdP, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.
4. Choose the *Enriched Token Claims* list item.
5. Add the claims as received from the corporate IdP with the new values to be sent to the application.
6. Save your configuration.

   If the operation is successful, you receive the message `Identity provider "<name of identity provider>" updated`.

1.7.16.4.3.2 (Optional) Configure the Subject Name Identifier Sent to the OpenID Connect Corporate IdP

Define the claim which is used as subject name identifier.

Prerequisites

You have enabled the *Use Identity Authentication user store* option. For more information, see Configure Identity Federation [page 2614].

Context

In this scenario, the tenant administrator can define the claim from the token of the corporate identity provider which Identity Authentication should use as subject name identifier. The Subject Name Identifier configuration defines with which value the identity provider user will be searched in the Identity Authentication user store. For more information, see the Context of Configure Identity Federation.

To define the claim which is used as subject name identifier, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.
4. Under *Trust*, choose *Subject Name Identifier*.
5. Select the Subject Name Identifier from the following:
   - *None* - Subject claim (`sub`) is used as subject name identifier. Corporate IdP decides which attribute to use.
   - *Email* - Email claim (`email`) is used as subject name identifier.
6. Save your selection.

   Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Related Information

Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]
Choose Identity Provider Type [page 2602]

1.7.16.4.3.3 Configure PKCE for Corporate Identity Providers

If your corporate identity provider supports Proof Key for Code Exchange (PKCE) and you have public applications that aren't capable of keeping client secrets, such as mobile applications, native applications, and single page applications, we recommend enabling this feature.

Context

Proof Key for Code Exchange (PKCE) is an enhancement of the authorization code flow to mitigate the threat of malicious actors from intercepting the authorization code.

> **Note**
>
> We only support the code challenge method S256.

For more information, see RFC7636 .

Procedure

1. In the administration console for SAP Cloud Identity Services, navigate to the OpenID Connect configuration of your corporate identity provider.

   For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
2. Enable the *Enable PKCE (S256)* check box.

   Use the *Validate* button to confirm that the configuration is still working.
3. Save your entries.

Related Information

Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650]

1.7.16.4.3.4 Enforce Nonces for Corporate Identity Providers

Some corporate identity providers require that applications send nonces. If your applications don't comply, enable this feature to ensure that one is sent.

Context

A nonce is a string associated with a client session and token and is used to mitigate replay attacks. If an application supplies a nonce, Identity Authentication forwards the nonce with requests to the corporate identity provider. By default, if there's no nonce, then Identity Authentication just forwards the request as is. When this feature is enabled and an application doesn't supply a nonce, Identity Authentication generates nonces before forwarding requests to the corporate identity provider.

Procedure

1. In the administration console for SAP Cloud Identity Services, navigate to the OpenID Connect configuration of your corporate identity provider.

   For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
2. Enable the *Enforce Nonce* check box.

   Use the *Validate* button to confirm that the configuration is still working.
3. Save your entries.

1.7.16.4.3.5 Disable ID Token Hints for Corporate Identity Providers

Corporate identity providers sometimes have trouble when the ID token is included as a URL parameter in logout requests. Use this option to disable the inclusion of the ID token.

Context

Identity Authentication includes the ID token in the `id_token_hint` URL parameter. This parameter can help the corporate identity provider identify the applications relevant to this call. For example, the user triggered a logout and the identity provider needs to identify all the applications related to the session. Including the ID token can exceed the length of URL that the corporate identity provider can consume. Your best option is then to disable the `id_token_hint`.

Procedure

1. In the administration console for SAP Cloud Identity Services, navigate to the OpenID Connect configuration of your corporate identity provider.

   For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
2. Enable the *Disable Logout ID Token Hint* check box.
3. Save your entries.

1.7.16.4.3.6 Enforce Issuer Validation for Corporate Identity Providers

To mitigate mix-up attacks, require corporate identity providers acting as authorization servers to identify themselves in their responses. The OAuth 2.0 Authorization Framework, as defined in RFC6749 , doesn't require the authorization server to identify itself in its responses for all grant types. Enable this option to require the corporate identity provider to identify itself in the `iss` parameter of the response.

Prerequisites

> ⚠ Caution
>
> Make sure that your corporate identity provider supports and is configured to issue the `iss` parameter. If the corporate identity provider doesn't include this parameter, SAP Cloud Identity Services rejects the response. You can't use this corporate identity provider for authentication as long as issuer validation is enforced.

To check if you corporate identity provider supports this feature, visit its discovery endpoint and look for `"authorization_response_iss_parameter_supported":true` . For an example of the discovery endpoint, see `https://accounts.sap.com/.well-known/openid-configuration`.

The service also rejects responses that include values in `iss` that aren't trusted identity providers. Verify that the corporate identity provider sends the issuer in your trust configuration.

For more information, Configure Trust with OpenID Connect Corporate Identity Provider [page 2579]

Context

With this implementation, SAP Cloud Identity Services supports RFC9207 .

Procedure

1. In the administration console for SAP Cloud Identity Services, navigate to the OpenID Connect configuration of your corporate identity provider.

   For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
2. Enable the *Enforce Issuer Validation* check box.
3. Use the *Validate* button to confirm that the configuration is still working.
4. Save your entries.

1.7.16.4.3.7 Elliptic Curve Signing Certificates

SAP Cloud Identity Services supports elliptic curve (EC) signing certificates for use with OpenID Connect corporate identity providers that require EC-based signatures.

What Are Elliptic Curve Signing Certificates

Signing certificates allow SAP Cloud Identity Services to sign tokens and requests using a private key so that the recipient can verify the signature using the corresponding public key. By default, SAP Cloud Identity Services uses RSA-based signing certificates (RS256).

Elliptic curve (EC) signing certificates use the ECDSA algorithm family. The following EC algorithms are supported:

Algorithm	Standard Name	Curve
ES256	ECDSA using P-256 and SHA-256	P-256 (secp256r1)

Algorithm	Standard Name	Curve
ES384	ECDSA using P-384 and SHA-384	P-384 (secp384r1)
ES512	ECDSA using P-521 and SHA-512	P-521 (secp521r1)

EC algorithms produce shorter signatures and keys than RSA at equivalent security levels. Some corporate identity providers, particularly those that follow national digital identity standards, accept only EC-signed tokens.

Once you create an EC certificate, you assign it as the *Active* signing certificate in the OpenID Connect configuration of a specific corporate identity provider. This design allows you to share a single EC certificate across multiple corporate identity providers, while each corporate identity provider can independently switch to a different certificate without affecting others.

You can also generate EC certificates through the SAP Cloud Identity Services REST API. Specify `ES256`, `ES384`, or `ES512` as the value of the algorithm parameter in the certificate generation request.

Scope and Constraints

EC signing certificates in SAP Cloud Identity Services have the following scope:

Scope of EC Signing Certificates

Scope	Description
Supported use	Signing of tokens and requests sent toward an OpenID Connect corporate identity provider when you select the EC certificate as the active certificate for that corporate identity provider.
Not supported	You cannot use EC certificates for application token signing (tokens issued to end-user applications). They don't appear in application-level signing certificate lists. **Note** You cannot set EC certificates as the tenant default signing certificate. The tenant default must remain an RSA certificate (RS256 or RS512). If you don't explicitly select a certificate for a corporate identity provider, the system uses the tenant default RSA certificate.

Configuration Overview

To use an EC signing certificate with a corporate identity provider:

1. Generate an EC signing certificate at tenant level. See Generate Elliptic Curve Signing Certificates [page 2593].

2. Assign the certificate as the active signing certificate for the corporate identity provider. See Configure Identity Provider Certificates for Corporate Identity Providers [page 2594].
3. Provide the public key of the certificate to the corporate identity provider for signature verification. The public key is available in the JWKS endpoint of your SAP Cloud Identity Services tenant.

1.7.16.4.3.7.1 Generate Elliptic Curve Signing Certificates

Generate a signing certificate that uses an elliptic curve (EC) algorithm so that it can be assigned as the active signing certificate for a specific corporate identity provider.

Prerequisites

You understand the following constraints before generating an EC certificate:

- EC signing certificates can only be used as the active signing certificate for corporate identity providers. They are not available for application token signing and cannot be set as the tenant default.
- To assign the generated certificate to a corporate identity provider, see Configure Identity Provider Certificates for Corporate Identity Providers [page 2594].

Context

SAP Cloud Identity Services supports elliptic curve (EC) signing certificates at the tenant level. EC certificates use the ECDSA algorithm family (ES256, ES384, ES512) and can be assigned per corporate identity provider, allowing each corporate identity provider to use a different signing algorithm and key if required.

> ⚠ Restriction
>
> EC certificates cannot be configured as the *Default* signing certificate on tenant level. The tenant default must use an RSA algorithm (RS256 or RS512). EC certificates are only applied when explicitly assigned as the active certificate in the configuration of a specific corporate identity provider.

Procedure

1. In the SAP Cloud Identity Services admin console, go to *Tenant Settings* > *Single Sign-On*.
2. Under *OpenID Connect Configuration*, find the *Signing Certificates* section and choose *Generate New Certificate*.
3. From the *Algorithm* dropdown list, select the elliptic curve algorithm to use.

Algorithm	Curve	Hash
ES256	P-256	SHA-256
ES384	P-384	SHA-384
ES512	P-521	SHA-512

> **Note**
>
> For elliptic curve algorithms, the *Key Size* field is not applicable. The key size is determined by the selected curve and is not configurable.

4. Select the certificate *Validity* (1, 3, 6 months, 1, 3, 5, or 10 years).
5. Choose *Generate* to create the certificate.

Results

The new certificate appears in the *Signing Certificates* list with its algorithm (for example, *ES256*) shown in the *Algorithm* column. The certificate is not set as *Default* and is not shown in application-level signing certificate lists.

You can now assign this certificate as the active signing certificate for a corporate identity provider.

Next Steps

Assign the certificate to one or more corporate identity providers. See Configure Identity Provider Certificates for Corporate Identity Providers [page 2594].

1.7.16.4.3.7.2 Configure Identity Provider Certificates for Corporate Identity Providers

Select the signing certificate that SAP Cloud Identity Services uses when communicating with a specific OpenID Connect corporate identity provider.

Prerequisites

Generate the signing certificate you want to use. The certificate must exist in the tenant-level signing certificate list before you can assign it here. For more information, see the following:

- For RSA certificates (RS256, RS512): Tenant OpenID Connect (OIDC) Configurations [page 2117].
- For elliptic curve certificates (ES256, ES384, ES512): Generate Elliptic Curve Signing Certificates [page 2593].

Context

The *Identity Provider Certificates* section in the OpenID Connect configuration of a corporate identity provider controls which signing certificate SAP Cloud Identity Services uses when sending signed requests or tokens to that corporate identity provider. All signing certificates created at tenant level are available for selection here, regardless of algorithm.

Select an elliptic curve certificate (ES256, ES384, or ES512) to meet the signing algorithm requirements of corporate identity providers that only accept EC-based signatures.

> **Note**
>
> You cannot generate new signing certificates from this section. Certificate generation is only available at tenant level under *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration*.

Procedure

1. In the SAP Cloud Identity Services admin console, go to *Applications and Resources* > *Identity Providers*.
2. Select the corporate identity provider whose signing certificate you want to configure.
3. Choose the *OpenID Connect Configuration* tab.
4. In the *Identity Provider Certificates* section, review the list of available signing certificates.

   The table displays all signing certificates configured at tenant level. Each row includes the following information:

Column	Description
Certificate	The subject name or thumbprint of the certificate.
Algorithm	The signing algorithm, such as RS256, RS512, ES256, ES384, or ES512.
Valid Until	The expiry date of the certificate.
Active	Indicates the certificate currently selected as active for this corporate identity provider.

5. Select *Active* for the certificate you want to assign to this corporate identity provider.

   > **Note**
   >
   > Only one certificate can be active at a time for a given corporate identity provider. When you select a new certificate, the system deactivates the previously active one for this identity provider.

6. Save your changes.

Results

SAP Cloud Identity Services uses the selected certificate when signing requests sent to this corporate identity provider. If you selected an elliptic curve certificate, the system uses the EC algorithm defined by that certificate (ES256, ES384, or ES512) for signing.

The tenant *Default* certificate continues to be used for all other signing operations not covered by a corporate identity provider-specific selection, such as application token signing.

Next Steps

Verify that the corporate identity provider accepts tokens signed with the selected algorithm by testing the authentication flow.

API Reference: Certificate Generation — Algorithm Parameter

1.7.16.4.4 Service Provider-Initiated Logout with Corporate Identity Providers

In this scenario, Identity Authentication is configured as an identity provider proxy and the corporate identity provider acts as an authenticating identity provider to the application. When a user triggers logout at an application, this request is propagated to Identity Authentication and any corporate identity providers, while the response returns by the same route.

The logout procedure is triggered by the user at the service provider and results in a logout request sent to the identity provider proxy. Consequently, the identity provider proxy processes the request and destroys any local session information about the user. The identity provider proxy then checks whether there are other service providers in the single sign-on (SSO) session and sends logout requests to all of them. In return, the service providers send logout responses to the identity provider proxy informing it that the logout process is successful. Finally, the identity provider proxy sends a logout response to the original requesting service provider or the service provider of the application.

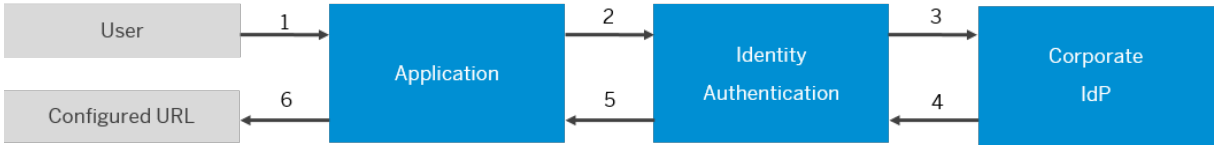
Depending on the protocol used to trust the corporate identity provider, you have different options for configuring logout redirect URLs. See the following table for details.

Protocol Differences for Logout Redirect URLs

Protocol of Service Provider	Options for Logout Redirect URL
SAML	You can configure a URL which is sent in the SAML 2.0 Logout Response as an extension. The URL can be used to redirect the users after logging out of the application. The URL is specific for each corporate identity provider with which Identity Authentication has established trust.
OIDC	If a client OpenID Connect (OIDC) application doesn't specify a post logout redirect URI in its logout request, you can specify a fallback URL. The service redirects the client to this URL after a successful logout.

Corporate Identity Provider Logout Flow

When Identity Authentication acts as a proxy to delegate authentication to a corporate identity provider, and the user who is logged on to one or more applications chooses the *Log Out* link in one of the applications, the following flow is in applies:



Logout Flow with Corporate Identity Providers

1. The user triggers a logout from the application.
2. Identity Authentication checks if the user is logged on to other applications. If yes, Identity Authentication sends logout requests to the applications, and closes the sessions.
3. Identity Authentication sends logout requests to the corporate identity provider or corporate identity providers, if there are more than one.
4. The user is logged out of the corporate identity providers.
5. The user is logged out of Identity Authentication.
    - For SAML: If the Redirect URL option is configured in the administration console for SAP Cloud Identity Services, the URL is sent as an extension in the SAML 2.0 Logout Response. This option can be used by the application to redirect the user to the destination from the link configured for the specific corporate identity provider.

      > ### Note
      >
      > This step is valid only if the application supports the redirect of the user, such as SAP SuccessFactors HCM Suite.

    - For OIDC: Applications should provide the `post_logout_redirect_uri` parameter with their logout request. If applications don't provide this parameter, you can configure a fallback URL. Otherwise, this configuration is ignored.
      For more information, see Call Identity Authentication End Session Endpoint [page 2740].

6. A logout response is sent to the initiating application.
   The response can differ depending on the protocol.
   - For SAML: The SAML service provider redirects to the Logout Redirect URL which was sent as an extension.
   - For OIDC: The application can redirect the user further.

1.7.16.4.4.1 Configure the Logout Redirect URL for Corporate Identity Providers

As a tenant administrator, you can configure an optional logout redirect URL to be used when the conditions apply.

Context

For more information about the conditions, see Service Provider-Initiated Logout with Corporate Identity Providers [page 2596].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].
4. Choose *Logout Redirect URL*.
5. Enter the required data.
6. Save your entries.

Results

Once the user has logged out of the application, Identity Authentication sends:

- For SAML: The logout redirect URL in the SAML 2.0 Response as an extension to the application. The logout redirect URL can be used by the application to redirect the user to the URL configured for the corporate identity provider.
- For OIDC: The logout response to the provided `post_logout_redirect_uri` or fallbacks to logout redirect URL configured for the corporate identity provider.

Single Logout Flows [page 2887]

1.7.16.4.5 Switch Protocols for Corporate Identity Providers

To take advantage of features of other protocols, switch the protocol of your corporate identity provider, for example from SAML to OpenID Connect (OIDC).

SAML isn't obsolete, but the trend is clear that many corporate identity providers are offering more new features with OIDC and not SAML. OIDC also enables you to take advantage of token exchange scenarios to support principal propagation. However, switching from OIDC to SAML is also possible.

To support your move to a new protocol for your corporate identity provider, you can switch all your applications at once or move one application at a time.

1.7.16.4.5.1 Impact on Applications

While this configuration doesn't necessarily affect your applications directly, what is application-specific are the attribute mappings between the attributes the corporate identity provider sends and the attributes the application needs. The identity provider might send different attribute names with the new protocol or even different values, for example, a different subject.

When identity federation is enabled, these mappings are application-specific in Identity Authentication.

For more information, see Configure Identity Federation [page 2614].

For each application, check the configurations, such as:

- Attribute mappings
- Configuration of SAML 2.0 request to corporate identity providers that includes authentication context and issuer.
- Identity provider-initiated single sign-on
  OIDC identity providers don't support such options. Switching to OIDC can break a scenario.
- You can't configure the signing and encryption methods for JWT tokens in OIDC identity providers.
- Single logout isn't supported by all OIDC providers.

1.7.16.4.5.2 Switch All Applications at Once

If you're confident that the new integration with the corporate identity provider will work immediately or any issues can be solved in your maintenance window, you can switch to the new corporate identity provider all at once.

Prerequisites

Plan for some downtime during the switch over.

Context

- Advantage: Efficiency. Move many applications to the new protocol at once.
- Disadvantage: Risk. Unless you've configured a test tenant with your corporate identity provider and your applications, you risk downtime if the applications encounter problems with the new setup.

Procedure

1. Go to the *Identity Provider Type* of your identity provider configuration and change the protocol.

   For more information, see Choose Identity Provider Type [page 2602].
2. Make any protocol-specific configurations.

   See also:

   - Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]
   - Configure Trust with OpenID Connect Corporate Identity Provider [page 2579]
3. Make any application-specific configurations.

   For more information, see Impact on Applications [page 2599].

1.7.16.4.5.3 Switch One Application at a Time

If you have many applications, this approach requires more time. However, you can observe any changes in the behavior of your applications and fix them.

Context

- Advantage: Lower risk. If you have many applications, the potential for downtime is lower. You only migrate one application at a time.
- Disadvantage: Time. It takes longer to migrate all applications to the new protocol, because you migrate one application at a time.

Procedure

1. Create a new identity provider configuration under the new protocol by copying the configuration of your existing corporate identity provider under the old protocol.

   Use the *Copy Settings from Identity Provider* option.

   For more information, see Create Corporate IdP in Administration Console [page 2558].
2. Make any protocol-specific configurations.

   See also:

   - Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]
   - Configure Trust with OpenID Connect Corporate Identity Provider [page 2579]
3. In each application configuration, change the identity provider to the new copy under the new protocol.

   For more information, see Authenticating Identity Provider for an Application [page 2065].
4. Make any application-specific configurations.

   For more information, see Impact on Applications [page 2599].
5. Check that you've moved all your applications from the old identity provider configuration.

   To see a list of the applications that use your old identity provider configuration, go to the identity provider configuration and choose *Trusting Applications*.
6. When the list of *Trusting Applications* is empty, delete the old identity provider configuration.

   For more information, see Delete Corporate Identity Providers [page 2619].

1.7.16.4.6 Choose Identity Provider Type

This topic shows you how to choose a type for the corporate identity provider.

Prerequisites

You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Choose *Identity Provider Type*.
5. Select the radio button for the type of the identity provider.

   You can choose one of the following options:

   - SAML 2.0 Compliant
   - SAP Single Sign-On (SAML 2.0)
   - Microsoft ADFS / Entra ID (SAML 2.0)

     > ⚠ Caution
     >
     > For this type the digest algorithm of the corporate identity provider must be *SHA-256*. For more information, see 2. Configure Trust on Identity Authentication Side in Configure Trust with Corporate Identity Provider [page 2560].

   - OpenID Connect Compliant
6. Save your selection.

   Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Related Information

Corporate Identity Providers [page 2556]
Edit Administrator Authorizations [page 2309]

1.7.16.4.7 Find Which Applications Trust a Corporate Identity Provider

The administration console for SAP Cloud Identity Services enables you to quickly find applications which trust a given corporate identity provider. This information enables you to find the applications you need to consider when you change or remove a corporate identity provider.

Context

Applications trust in corporate identity providers is founded in one or more of the following ways:

- Client authentication
  This source is configured by trust by issuer. For more information, see Configure JWT for OAuth Client Authentication [page 2003].
- Conditional authentication
  For more information, see Configure Conditional Authentication for an Application [page 2076].
- Trust identity providers
  For more information, see Enable SSO with Corporate Identity Providers [page 2087].

> ⓘ Note
>
> Only conditional authentication and trust in identity providers can't be combined.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Choose *Trust* > *Trusting Applications*.
   The system displays a list of applications which trust this corporate identity provider. Search for a specific application or sort by the source of trust.

Next Steps

To navigate to the source of the trust configuration in the relevant application, choose the ⊘ *(check mark)* icon.

1.7.16.4.8 Configure Login Hint Parameter

Tenant administrator can configure the login hint parameter via the administration console for SAP Cloud Identity Services.

Context

The configuration of the login hint parameter affects the following scenarios:

- Identity Authentication acting as proxy to delegate authentication to an external corporate identity provider (IdP). The user is authenticated via that corporate identity provider.
- Identity Authentication acting as a conditional proxy where an external corporate identity provider is configured to be used as an authenticating IdP under certain conditions.

The login hint parameter helps the user when he or she is known to the service provider (SP) or relying party. Thus it prevents the user from re-typing the user identifier on the logon. If the corporate IdP supports the login hint parameter, then it requests only the user credentials.

If the corporate IdP does not support the login hint parameter, it requires both the user identifier and password. You can configure the login hint parameter for corporate IdP via the administration console for SAP Cloud Identity Services.

There are two aspects in the configuration of the login hint parameter: the value of the parameter, and how it is sent to the corporate IdP. The *How it is sent to the corporate IdP* configuration is only relevant for SAML 2.0 corporate identity providers and depends on the *Value* configuration:

Configuration Options

Value	How it is sent to the corporate IdP	Additional Info
User Input	• Login Hint URL parameter - the login hint is sent in the URL as `login_hint parameter` • Authentication Request - the login hint is sent in the SAML 2.0 authentication request as <`Subject`> attribute (for SAML 2.0 only)	As `login_hint` will be sent the user identifier provided at the conditional authentication sign in screen of Identity Authentication.
None	no login hint parameter is sent	The user will need to provide user identifier and password at the corporate identity provider sign in screen.
User Attributes • Login Name • Email	• Login Hint URL parameter - the login hint is sent in the URL as `login_hint parameter` • Authentication Request - the login hint is sent in the SAML 2.0 authentication request as <`Subject`> attribute (for SAML 2.0 only)	As `login_hint` will be sent one of the following: • Login Name • Email .

> **Note**
>
> The *User Input* is the default value option.
>
> The *User Attributes* option is valid only for users that exist in the Identity Authentication local user store. If the user is missing the specified attribute in the configuration, then login hint parameter will not be sent to the corporate IdP.
>
> If the user does not exist in Identity Authentication local user store, then the User Input will be sent as login hint to the corporate IdP.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Set a value for the login hint parameter:
   - User Input
   - None
   - User Attribute (local users only)
5. (For SAML 2.0 providers only) Set how the login hint parameter should be sent to the corporate IdP:
   - *Login Hint URL parameter* -
   - *Authentication Request*

   > → Remember
   >
   > The options are valid only if *User Input* or *User Attribute (local users only)* values are set.

6. Save your configuration.

1.7.16.4.9 Create URLs to Access Applications with Specific Identity Providers

Enhance the user experience by eliminating the need for users to determine which identity provider to use. Users often don't have the context to choose the correct identity providers.

Sometimes you have multiple identity providers in your landscape, whether they are corporate identity providers or your SAP Cloud Identity Services - Identity Authentication tenant. By providing your users with preconfigured URLs, you can direct them to authenticate with specific identity providers for specific applications.

How you prepare these URLs depends on whether the user starts at the identity provider or at the application. It's further modified by your use case. Some typical use cases are described as follows.

Opting for the Local Identity Provider

You can enable users that are stored in SAP Cloud Identity Services to log on with their Identity Authentication credentials. Thus, the employees log on to the application with their corporate credentials, while the external users, such as clients, partners, or SAP support users are authenticated by the local Identity Authentication tenant. Another example is if you're developing an application and you want to use a test user in the local identity provider instead of creating a test user in the corporate identity provider. The following figure illustrates this architecture.

Sign On With the Local Identity Provider and not the Corporate Identity Provider

Example

Example approuter link:

```
https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
sap_idp=custom.sap
```

Note that the approuter needs the origin key for the custom identity provider for the SAP BTP account.

Example link:

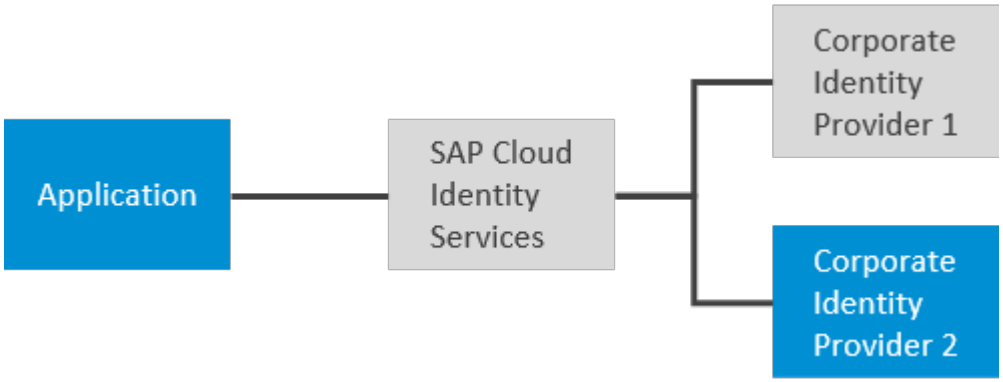
```
https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
my_sci_tenant.accounts.ondemand.com
```

Example with local value:

```
https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=local
```

Multiple Corporate Identity Providers

If your application doesn't define rules to determine which identity provider a user authenticates with, SAP Cloud Identity Services offers the choice to your users. To avoid users choosing the wrong identity provider, you can limit their choices. The following figure illustrates this architecture.

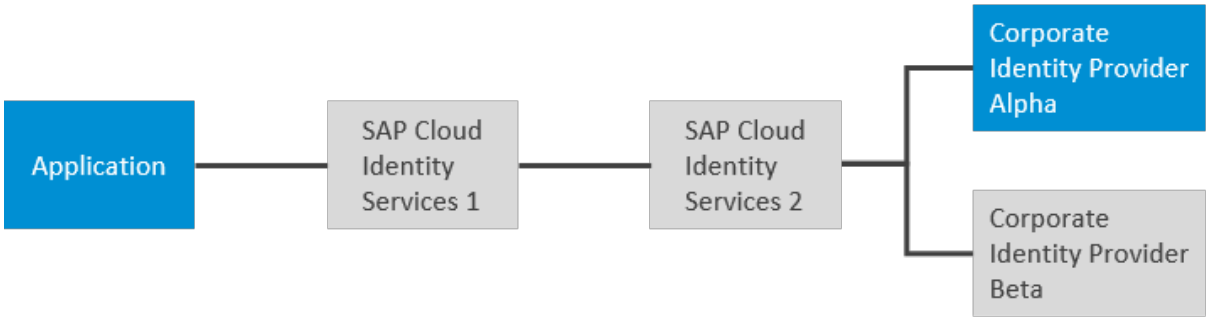


Help Direct Users to the Correct Identity Provider

> ### Example
>
> Example approuter link:
>
> ```
> https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
> sap_idp=https://corp_idp_2.mydomain.com
> ```
>
> Example link:
>
> ```
> https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
> corp_idp_2.mydomain.com
> ```

Deep Hierarchy of Identity Providers

Your landscape has multiple levels of identity providers, perhaps through subsidiaries and conglomerate organizations. You want to direct your users to a specific identity provider, but this identity provider isn't directly known by your SAP Cloud Identity Services tenant. In such cases, provide the chain of identity providers to which the user must be redirected to reach the authenticating identity provider. The following figure illustrates this architecture.



Deep Structure of Identity Providers

Example

Example approuter link:

```
https://approuter-myapplication.cfapps.eu20-001.hana.ondemand.com?
sap_idp=https://scis_2.mydomain.com,corp_idp_alpha.mydomain.com
```

Example link:

```
https://myapplication.cfapps.eu20-001.hana.ondemand.com?sap_idp=https://
scis_2.mydomain.com,corp_idp_alpha.mydomain.com
```

Identity-Provider-Initiated Single Sign-On

Restriction

This option is only supported by SAML.

Identity-provider-initiated single sign-on (IdP-initiated SSO) is used for central portals in an enterprise from which users access applications. Users log on to the central portal first. You need to identify the identity provider the user must log on with. You also need to identify the service provider that the user is forwarded to after authenticating. The identity provider can be SAP Cloud Identity Services or a corporate identity provider or a hierarchy of corporate identity providers. Another unique aspect of IdP-initiated SSO is that the URL pattern you use is determined by SAP Cloud Identity Services. Otherwise, the URL is defined by the application. The following figure illustrates this architecture.

Identity-Provider-Initiated Single Sign-On

Example

Example SAML URL:

```
https://my_sci_tenant.accounts.ondemand.com/saml2/idp/sso?sp=https://
myapplication.cfapps.eu20-001.hana.ondemand.com&idp=https://
corp_idp_1.mydomain.com
```

1.7.16.4.9.1 Creating URLs for Applications to Authenticate with Specific Identity Providers

The URL to access an application is generally determined by the application. When you have multiple identity providers available, you can steer users to the correct identity provider with the `idp` parameter.

Prerequisites

- You have set a corporate IdP as the default identity provider in the administration console.
  For more information, see Choose a Corporate Identity Provider as Default [page 2072].
- The application supports selection of the corporate IdP with the idp parameter in the application URL. See the documentation of the application.

  > **Example**
  >
  > Example: Many BTP applications use the application router, which requires the `sap_idp` query parameter.
  >
  > For more information, see @sap/approuter at *npm*.

- If you have enabled the *Allow Identity Authentication Users Log On* option, you can use the reserved name **`local`** to authenticate with your Identity Authentication tenant.
  For more information, see (Optional) Use the Allow Identity Authentication Users Log On Option [page 2074].

Procedure

Use the `idp` parameter in the URL for OIDC or in the URL or body for SAML.

> **Caution**
>
> It depends on the service provider whether the parameter can be passed in body or URL. Identity Authentication doesn't control how the SAML 2.0 request is sent.

Parameters

Parameter	Description
`idp`	Name of the identity provider as defined under the *Name* in the *Trust* configuration of the identity provider. • For SAML, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560]. • For OIDC, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579]. If you need a chain of identity providers, use a comma without spaces (,) to separate them. Use the value **`local`** to override the conditional authentication configuration and authenticate with Identity Authentication instead.

1.7.16.4.9.2 Creating URLs for IdP-Initiated Single Sign-On

Direct users to a authenticate at an IdP before accessing an application. For IdP-Initiated SSO, the URL syntax is determined by SAP Cloud Identity services.

Prerequisites

- You have enabled IdP-initiated Single Sign-On (SSO) from all configured corporate IdPs. For more information, see Enable SSO with Corporate Identity Providers [page 2087] .
- You have configured one of the following options:
- The application supports IdP-initiated Single Sign-On (SSO). For more information, see Security Assertion Markup Language (SAML) V2.0 Technical Overview .

Context

This option is available to SAML applications.

Procedure

Contruct the URL from the following pattern.

```
https://<tenant_ID>.accounts.ondemand.com/saml2/idp/sso?
sp=<sp_name>&idp=<corporateIdP1_name>,<corporateIdP2_name>
```

Parameters

Parameter	Description
`sp`	Redirect target after authentication. The `<sp_name>` value equals to the Entity ID of the service provider.
`idp`	Name of the identity provider as defined under the *Issuer* in the *Tenant Settings*. For more information, see Tenant SAML 2.0 Configurations [page 2103]. If you need a chain of identity providers, use a comma without spaces (,) to separate them.

> → Remember
>
> If there is more than one corporate IdP in the IdP-initiated link, use *HTTP-Redirect* as default binding in the trust configuration with SAML 2.0 Corporate Identity Provider. For more information, see Configure Trust on Identity Authentication Side [page 2562].

1.7.16.4.10 Forward All SSO Requests to Corporate IdP

Identity Authentication can be configured to forward all single sign-on(SSO) requests to the corporate identity provider.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured Identity Authentication to use a corporate identity provider as an external authenticating authority. For more information, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560] or Forward All SSO Requests to Corporate IdP [page 2611].
- You have selected the configured identity provider as the authenticating identity provider for your applications. For more information, see Choose Default Identity Provider for an Application [page 2067].

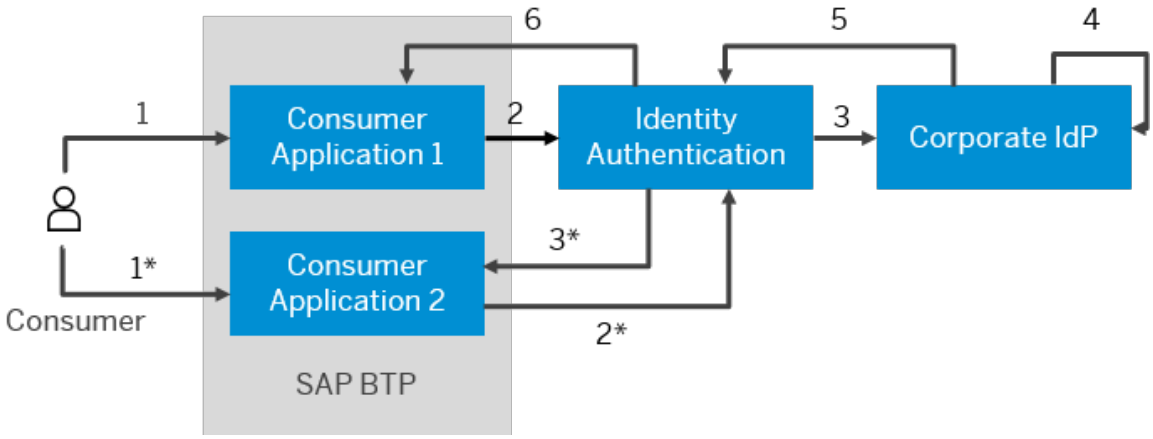
Context

The *Forward All SSO Requests to Corporate IdP* option allows the corporate identity provider (IdP) to process all single sign-on (SSO) requests when Identity Authentication acts as a proxy.

By default, the *Forward All SSO Requests to Corporate IdP* option is disabled. In this case Identity Authentication reuses the active session of the user.

When *Forward All SSO Requests to Corporate IdP* option is enabled, Identity Authentication sends new authentication request for each application.

Forward All SSO Requests to Corporate IdP Disabled



1. User tries to access *Application 1*.

2. *Application 1* sends authentication request to Identity Authentication.

3. Identity Authentication acts as proxy; forwards the request to corporate IdP.

4. Corporate IdP logs on the user.

5. Corporate IdP returns authentication response to Identity Authentication.

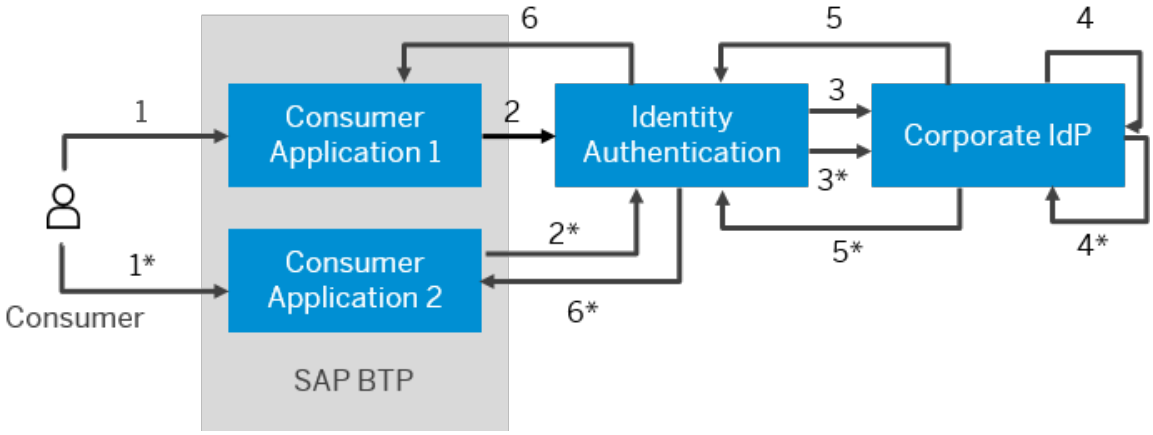
6. Identity Authentication returns authentication response to *Application 1*.

1*. User tries to access *Application 2*.

2*. *Application 2* sends authentication request to Identity Authentication.

3*. The user has an active session. Identity Authentication reuses the session and returns the authentication response to *Application 2*.

Forward All SSO Requests to Corporate IdP Enabled



1. User tries to access *Application 1*.

2. *Application 1* sends authentication request to Identity Authentication.

3. Identity Authentication acts as proxy; forwards the request to corporate IdP.

4. Corporate IdP logs on the user.

5. Corporate IdP returns authentication response to Identity Authentication.

6. Identity Authentication returns authentication response to *Application 1*.

1*. User tries to access *Application 2*.

2*. *Application 2* sends authentication request to Identity Authentication.

3*. Identity Authentication acts as proxy; it forwards the request to corporate IdP, though the user has an active session..

4*. Corporate IdP logs on the user.

5*. Corporate IdP returns new authentication response to Identity Authentication.

6*. Identity Authentication returns new authentication response to *Application 2*.

To enable the *Forward All SSO Requests to Corporate IdP*, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure for *Forward All SSO Requests to Corporate IdP*.
    - If you do not have an identity provider in your list, click the *Add* button to create one, and proceed with the configuration.
    - If you have an identity provider in your list, choose the one that you want to configure.
4. Use the slider next to *Forward All SSO Requests to Corporate IdP* to enable or disable it.

    If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

1.7.16.4.11 Configure Identity Federation

Tenant administrators can configure whether the attributes are taken from the assertion of the corporate identity provider or from the user store of Identity Authentication, and can restrict access based on the user profile.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured Identity Authentication to use a corporate identity provider as an external authenticating authority. For more information, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560] or Configure Identity Federation [page 2614].
- You have selected the configured identity provider as the authenticating identity provider for your application. For more information, see Choose Default Identity Provider for an Application [page 2067].
- You have imported the users, authenticated by the corporate identity provider, in Identity Authentication. For more information about how to import users, see Import or Update Users for a Specific Application [page 2348].

Context

The *Identity Federation* option allows you to choose whether the user attributes are taken from the corporate IdP assertion or from Identity Authentication user store. You can also restrict access based on the user profile, and additionally apply the custom application configurations for the authentication and access policies.

User Store

By default, *Use Identity Authentication user store* is disabled.

In scenarios when the application is using for authentication a corporate identity provider, and the *Use Identity Authentication user store* option is disabled, the user attributes, the name ID attribute, and the default attributes configurations in the administration console for SAP Cloud Identity Services are not relevant. In such scenarios, Identity Authentication sends to the application the same attributes it has received from the corporate identity provider. For more information about the corporate identity provider scenario, see Corporate Identity Providers [page 2556].

When *Use Identity Authentication user store* option is enabled, the application checks if the users authenticated by the corporate identity provider exist in the Identity Directory, the user store of Identity Authentication. The existence check is done with the name identifier sent by the corporate identity provider for the identifying attributes `uid`, `loginName`, `emails` and `phoneNumber`.

For users that exist in the Identity Directory, data from the user store is taken and the subject name identifier, assertion and default attributes according to the application configuration are sent. For users with no profile in Identity Authentication, the application receives the nameID attribute from the corporate IdP assertion, and the attributes according to the application configuration.

User Access

When *Allow Identity Authentication users only* is enabled, only the users that exist in Identity Authentication can access the application.

By default, *Allow Identity Authentication users only* is disabled, and all users successfully authenticated to the corporate IdP are allowed.

Restrict Logon to Members of Certain Groups

You can assign a group or groups to the corporate identity provider. Only users from the Identity Authentication that are members of the assigned group can access the application.

> → Remember
>
> You can assign groups, only when *Allow Identity Authentication users only* option is enabled. If disabled, the assigned groups option is not taken into consideration.

Restrict Logon to Users with Certain Email Domains

Only users from the Identity Authentication user store whose email domains are allowed can access the application.

> → Remember
>
> You can allow email domains from the allow list, only when the *Allow Identity Authentication users only* option is enabled. If disabled, the allow list option is not taken into consideration.

Application Configuration

By default, *Apply Application Configurations* is disabled.

When enabled, the custom application configurations for authentication and access policies are applied.

When this option is enabled, the user is authenticated by the corporate IdP, then Identity Authentication checks for the configurations for authentication and access policies on application level, and applies them. They include Risk-Based-Authentication, Terms of Use, Privacy Policy, Upgrade and Registration Forms.

> → Remember
>
> The concurrent user access configuration is always applied for the application regardless of the *Apply Application Configurations* state.

Use Identity Authentication user store

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure for *Identity Federation*.

- If you do not have an identity provider in your list, click the *Add* button to create one, and proceed with the configuration.
- If you have an identity provider in your list, choose the one that you want to configure.

4. Choose *Identity Federation* to configure the options.
5. Use the slider next to *Use Identity Authentication user store* to enable it.

   If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

Allow Identity Authentication users only

Prerequisites

You have enabled *Use Identity Authentication user store* option. For more information about how to enable the option, see *Use Identity Authentication user store* in this topic.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure for *Identity Federation*.
   - If you do not have an identity provider in your list, click the *Add* button to create one, and proceed with the configuration.
   - If you have an identity provider in your list, choose the one that you want to configure.
4. Choose *Identity Federation* to configure the options.
5. Use the slider next to *Allow Identity Authentication users only* to enable it.

   If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

Apply Application Configurations

Prerequisites

You have enabled *Allow Identity Authentication users only* option. For more information about how to enable the option, see *Allow Identity Authentication users only* in this topic.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure for *Identity Federation*.
   - If you do not have an identity provider in your list, click the *Add* button to create one, and proceed with the configuration.
   - If you have an identity provider in your list, choose the one that you want to configure.
4. Choose *Identity Federation* to configure the options.
5. Use the slider next to *Apply Application Configurations* to enable it.

   If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

(Optional) Restrict Logon Only to Members of Certain Groups

Prerequisites

You have enabled *Allow Identity Authentication users only* option. For more information about how to enable the option, see *Allow Identity Authentication users only* in this topic.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Choose *Identity Federation*.

   You will see a list of the groups assigned to this corporate identity provider. If no groups are assigned, the list will be empty.
5. Choose the *Add* button.
6. Select the groups that you want to assign to this corporate identity provider.

   The list does not include the groups that are already assigned to the corporate identity provider.

   If you do not have any groups in your list, you can create one. For more details about how to create groups and assign the group to a user, see Related Information.
7. Save your changes.

If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

> **Note**
>
> To unassign groups, select the groups you want to unassign, choose the *Remove* button, and confirm the operation in the dialog.
>
> Users that belong only to the unassigned groups will not be able to access the application any more.

(Optional) Restrict Logon Only to Users with Specific Email Domains

Prerequisites

You have enabled *Allow Identity Authentication users only* option. For more information about how to enable the option, see *Allow Identity Authentication users only* in this topic.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > **→ Tip**
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Choose *Identity Federation*.

   You will see a list of the allowed email domains for this corporate identity provider. If no email domains are allowed, the list will be empty.
5. Choose the *Add* button.
6. Type the email domains that you want to allow for this corporate identity provider.
7. Save your changes.

   If the operation is successful, the system displays the message `Identity provider <name of identity provider> updated`.

   > **Note**
   >
   > To remove the email domains, select them from the list, choose the *Remove* button, and confirm the operation in the dialog.

1.7.16.4.12 Delete Corporate Identity Providers

As a tenant administrator, you can delete one or more corporate identity providers in a tenant of Identity Authentication.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have at least one corporate identity provider that you want to delete.
- The identity provider you want to delete must not be used by an application. For more information about how to choose an identity provider for an application, see Authenticating Identity Provider for an Application [page 2065].

Context

A *Delete Identity Providers* operation removes the identity providers and all of their configurations from the tenant of Identity Authentication.

> **Note**
>
> If you want to delete an identity provider that is in use for conditional authentication, client authentication, or is set as a trusted identity provider or a default identity provider for an application, edit the rules or the client authentication, or change the trusted or default identity provider for the application. For more information see Authenticating Identity Provider for an Application [page 2065].

To delete one or more identity providers, not used not used by applications in the tenant, choose one of the following options:

Delete Multiple Corporate Identity Providers

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Choose the icon in the left-hand panel.

   This operation activates the *Delete Identity Providers* mode.
4. Select the identity provider or identity providers that you want to delete.

5. Choose the *Delete* button.
6. Confirm the operation in the pop-up dialog.

   The system deletes only the identity providers that are not used by applications.

   Once the identity provider or identity providers have been deleted, the system displays the message `<number> identity providers deleted`.

Delete Single Corporate Identity Provider

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the identity provider that you want to delete.

   > → Tip
   >
   > Type the name of the identity provider in the search field to filter the list items.

4. Choose the *Delete* button in the right-hand panel to delete the selected corporate identity provider.
5. Confirm the operation in the pop-up dialog.

   The system deletes only the identity provider that is not used by applications.

   Once the identity provider has been deleted, the system displays the message `Identity provider deleted`.

1.7.17.1 Configure Authentication Provider To Migrate User Passwords from SAP SuccessFactors Systems to Identity Authentication

Prerequisites

- You have provisioned the users from `SAP SuccessFactors` to Identity Authentication.
- Users provisioned to Identity Authentication have the `sourceSystem` attribute with value `100`, and the `sourceSystemId` with value equal to the SAP SuccessFactors company ID.
  You can find information about the user's authentication provider type and system ID under the legal tab in the user details section. For more information, see List and Edit User Details [page 2361].

Context

In this scenario, you have an SAP SuccessFactors instance integrated with Identity Authentication. In the SAP SuccessFactors instance, there are users that log on with username and password (also known as password or non-sso users). The authentication provider opportunity gives the possibility these users to be migrated and to use Identity Authentication without the need to change the passwords that they already have. The password of each SAP SuccessFactors user is migrated once only during his or her first successful logon after the configuration of the authentication provider scenario in Identity Authentication. After that the user passwords are managed by Identity Authentication.

The first logon after the migration must be with a username and password. After this first successful logon, the user can use any other allowed logon identifier.

> → Remember
>
> If a user has enabled the *Remember me* option, when that user changes his or her password in the external authentication provider, the remember me cookie isn't invalidated. For more information, see Use the Remember Me Option [page 2774].

To configure a authentication provider, follow the steps below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new authentication provider to the list.
4. Under *Configuration*, make the corresponding entries in the configuration for the target system you want to create:

Configurations	Description
Display Name	The name of the configuration.
Type	Select the *SuccessFactors* type.
Company ID	The company of the authentication provider.

Configurations	Description
Password Validation URL	The URL endpoint for validation of the users name and password. It can be provided by the authentication provider administrator. **Note** The URl must have the following pattern: `https://<SuccessFactors_API_Host>/odata/v2/restricted/validateUser` Replace the host `<SuccessFactors_API_host>` with the Authentication URL host from the SAP SuccessFactors Data Centers Mapping to Authentication URL [page 2634] document. Plain HTTP is supported for testing purposes only. Make sure that you use the encrypted HTTPS protocol for productive systems. For more information about the mapping between the SAP SuccessFactors data centers and the password validation URL, see SAP SuccessFactors Data Centers Mapping to Authentication URL [page 2634]. **→ Remember** If you choose the *X.509* certificate as your *Authentication Type*, you'll need to add ".cert" after the subdomain part of the URL. For example: `https://exampleapi.cert.sapsf.com/odata/v2/restricted/validateUser`

Configurations	Description
• *Authentication Type*	Choose: • *Basic* - provide *Technical User* and *Technical User Secret*: *Technical User* Technical user added in the authentication provider that has administrator permissions to access the OData API. It can be provided by the external authentication provider administrator. For more information of the permission settings of the user, see Setting Up an API User for Sync Jobs in SAP SuccessFactors (Basic Authentication Method). *Technical User Secret* Password set on the technical user. It can be provided by the authentication provider administrator. → Tip For productive systems, we recommend that you use passwords that are difficult to be guessed. • *X.509* Enter CN for the certificate in the provided field. Once the certificate is generated, you can view its details. The validity of the certificate is 1 year. ⓘ Note You can choose the option for automatic regeneration of the certificate by selecting the *Automatic Renewal* checkbox. Two weeks before the expiry of the certificate, it is regenerated. The renewed certificate will have the same DN. → Remember If you choose the *X.509* certificate as your *Authentication Type*, you'll need to upload that certificate into SAP SuccessFactors to register Identity Authentication for incoming calls using *X.509* certificate-based authentication. Refer to Upgrade to X.509 Certificate-Based Authentication for Incoming Calls for the steps to complete the upload. → Tip To create a *X.509* certificate to use it as *Authentication Type* for the authentication provider:

Configurations	Description

	1. Open the authentication provider created in the administration console.
	2. Choose the *display button* under the *Actions* column.
	3. Copy content of the *X.509* certificate from the popup window.
	4. Create a `cer.` file in the following way:
	Sample Code
	`-----BEGIN CERTIFICATE-----`
	`<Copied content of the X.509 certificate>`
	`-----END CERTIFICATE-----`

First Logon Behavior	Choose if a user whose password doesn't meet the password policy requirements of the application must reset or change it after the first successful logon. • *Change password* - The user will be presented a dialog to change their password. The new password must meet the current password policy. This is the default choice. • *Reset password* - The user receives the reset password link by email.

5. Save your configuration.

   The system displays the message `Authentication provider <id of the system> created`.

   If you have chosen *Authentication Type - X.509*, the certificate is generated after saving the configuration.
6. **Optional:** Choose *Test Connection* to test the authentication provider configuration.

Next Steps

> **Note**
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

- (Optional) To edit an existing authentication provider configuration, select *provider you want to edit* > *Edit button* > *make the necessary changes* > *Save*.
- (Optional) To change the display name of an existing authentication provider, select the authentication provider whose name you want to change, choose the *Edit icon*, provide the new name, and save your changes.

Migrating Passwords from SAP SuccessFactors to Identity Authentication Service

1.7.17.2 Configure Authentication Provider To Migrate User Passwords from SAP Learning Management System to Identity Authentication

Prerequisites

- You have provisioned the users from `SAP Learning Management System` to Identity Authentication.
- Users provisioned to Identity Authentication have the `sourceSystem` attribute with value `101`, and the `sourceSystemId` with value equal to the SAP Learning Management System tenant ID.
  You can find information about the user's authentication provider type and system ID under the legal tab in the user details section. For more information, see List and Edit User Details [page 2361].

Context

In this scenario, you have an SAP Learning Management System instance integrated with Identity Authentication. In the SAP Learning Management System instance there are users that log on with username and password (also known as External Learners). The authentication provider opportunity gives the possibility these users to be migrated and to use Identity Authentication without the need to change the passwords that they already have. The password of each SAP Learning Management System user is migrated once only during his or her first successful logon after the configuration of the authentication provider scenario in Identity Authentication. After that the user passwords are managed by Identity Authentication.

> → Remember
>
> If a user has enabled the *Remember me* option, when that user changes his or her password in the external authentication provider, the remember me cookie is not invalidated. For more information, see Use the Remember Me Option [page 2774].

To configure a authentication provider, follow the steps below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new authentication provider to the list.
4. Under *Configuration*, make the corresponding entries in the configuration for the target system you want to add:

Configurations	Description
Display Name	The name of the configuration.
Type	Select the *Learning Management System* type.
System ID	The ID of the authentication provider.
Password Validation URL	The URL endpoint for validation of the users name and password. It is automatically generated and has the following pattern: `https://<lms-system-id>.plateau.com/learning/rest/integrated/admin/Learner.svc/ias/v1/~validateCredentials` The *Password Validation URL* can be provided also by the authentication provider administrator. It must have the following pattern: `https://<lms-system-id>.plateau.com/learning/rest/integrated/admin/Learner.svc/ias/v1/~validateCredentials` Plain HTTP is supported for testing purposes only. Make sure that you use the encrypted HTTPS protocol for productive systems.

Configurations	Description
Authentication Type	Choose: • *Basic* - provide *Technical User* and *Technical User Secret*: *Technical User* Technical user added in the authentication provider that has administrator permissions to access the OData API. It can be provided by the external authentication provider administrator. *Technical User Secret* Secret set on the technical user. It can be provided by the authentication provider administrator. → Tip For productive systems, we recommend that you use passwords that are difficult to be guessed. • *X.509* Enter CN for the certificate in the provided field. Once the certificate is generated, you can view its details. The validity of the certificate is one year. ⓘ Note You can choose the option for automatic regeneration of the certificate by selecting the *Automatic Renewal* checkbox. Two weeks before the expiry of the certificate, it will be regenerated. The renewed certificate will have the same DN.
First Logon Behavior	Choose: • if a user whose password does not meet the password policy requirements of the application must reset or change it after the first successful logon. • if a user whose LMS password is expired must reset or change it after the first successful logon. The default choice is *Change password*.

5. Save your configuration.

   The system displays the message `Authentication provider <id of the system> created`.

   If you have chosen *Authentication Type - X.509*, the certificate is generated after saving the configuration.
6. **Optional:** Choose *Test Connection* to test the authentication provider configuration.

Next Steps

> **Note**
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

- (Optional) To edit an existing authentication provider configuration, select *provider you want to edit* > *Edit button* > *make the necessary changes* > *Save*.
- (Optional) To change the display name of an existing authentication provider, select the authentication provider whose name you want to change, choose the *Edit icon*, provide the new name, and save your changes.

1.7.17.3 Configure Authentication Provider To Migrate User Passwords from SAP Fieldglass to Identity Authentication

Prerequisites

- You have provisioned the users from SAP Fieldglass to Identity Authentication.
- Users provisioned to Identity Authentication have the `sourceSystem` attribute with value `102`, and the `sourceSystemId` with value equal to the SAP Fieldglass tenant ID.
  You can find information about the user's authentication provider type and system ID under the legal tab in the user details section. For more information, see List and Edit User Details [page 2361].

Context

In this scenario, you have an SAP Fieldglass instance integrated with Identity Authentication. In the SAP Fieldglass instance there are users that log on with username and password. The authentication provider opportunity gives the possibility these users to be migrated and to use Identity Authentication without the need to change the passwords that they already have. The password of each SAP Fieldglass user is migrated once only during his or her first successful logon after the configuration of the authentication provider scenario in Identity Authentication. After that the user passwords are managed by Identity Authentication.

> → Remember
>
> If a user has enabled the *Remember me* option, when that user changes his or her password in the external authentication provider, the remember me cookie is not invalidated. For more information, see Use the Remember Me Option [page 2774].

To configure a authentication provider, follow the steps below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new authentication provider to the list.
4. Under *Configuration*, make the corresponding entries in the configuration for the target system you want to add:

Configurations	Description
Display Name	The name of the configuration.
Type	Select the **`Fieldglass`** type.
Company Code	The company code of the authentication provider.
Password Validation URL	The URL endpoint for validation of the users name and password. It must have the following pattern: `https://<fieldglass_host>/api/v1/ias/passwordsync` Plain HTTP is supported for testing purposes only. Make sure that you use the encrypted HTTPS protocol for productive systems.
Technical User	Technical user added in the authentication provider that has administrator permissions to access the OData API. It can be provided by the external authentication provider administrator.

Configurations	Description
Technical User Secret	Secret set on the technical user. It can be provided by the authentication provider administrator. → Tip For productive systems, we recommend that you use passwords that are difficult to be guessed.
Token URL	Token endpoint to which the technical user is authenticated.
First Logon Behavior	Choose if a user whose password does not meet the password policy requirements of the application must reset or change it after the first successful logon. The default choice is *Change password*.

5. Save your configuration.

   The system displays the message `Authentication provider <id of the system> created`.
6. **Optional:** Choose *Test Connection* to test the authentication provider configuration.

Next Steps

> ⓘ Note
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

- (Optional) To edit an existing authentication provider configuration, select *provider you want to edit* > *Edit button* > *make the necessary changes* > *Save*.
- (Optional) To change the display name of an existing authentication provider, select the authentication provider whose name you want to change, choose the *Edit icon*, provide the new name, and save your changes.

1.7.17.4 Configure Authentication Provider To Migrate User Passwords from SAP Concur to Identity Authentication

Prerequisites

- You have provisioned the users from SAP Concur to Identity Authentication.
- Users provisioned to Identity Authentication have the `sourceSystem` attribute with value `103`, and the `sourceSystemId` with value equal to the SAP Concur tenant ID.
  You can find information about the user's authentication provider type and system ID under the legal tab in the user details section. For more information, see List and Edit User Details [page 2361].

Context

> → Remember
>
> If you have completed automated identity provisioning with SAP Cloud Identity Services for your organization, skip the procedure below. For more information, see Process.

In this scenario, you have an SAP Concur instance integrated with Identity Authentication. In the SAP Concur instance, there are users that log on with username and password. The authentication provider opportunity gives the possibility these users to be migrated and to use Identity Authentication without the need to change the passwords that they already have. The password of each SAP Concur user is migrated once only during his or her first successful logon after the configuration of the authentication provider scenario in Identity Authentication. After that the user passwords are managed by Identity Authentication.

> → Remember
>
> - If a user has enabled the *Remember me* option, when that user changes his or her password in the external authentication provider, the remember me cookie is not invalidated. For more information, see Use the Remember Me Option [page 2774].
> - If a user has a second-factor authentication configured for his profile, they will be asked to provide it together with the password.

To configure an authentication provider, follow the steps below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Authentication Providers* tile.
3. Press the *Create* button on the left-hand panel to add a new authentication provider to the list.
4. Under *Configuration*, make the corresponding entries in the configuration for the target system you want to add:

Configurations	Description
Display Name	The name of the configuration.
Type	Select the **`Concur`** type.
Company ID	The company ID of the authentication provider.
Password validation URL	The URL endpoint for validation of the users name and password. It must have the following pattern: `https://<concur_host>/password/v0/ias/passwordcheck` Plain HTTP is supported for testing purposes only. Make sure that you use the encrypted HTTPS protocol for productive systems.
Common Name (CN)	
First Logon Behavior	Choose if a user whose password does not meet the password policy requirements of the application must reset or change it after the first successful logon. The default choice is *Change password*.

5. Save your configuration.

   The system displays the message `Authentication provider <id of the system> created`.
6. **Optional:** Choose *Test Connection* to test the authentication provider configuration.

Next Steps

> ⓘ Note
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

- (Optional) To edit an existing authentication provider configuration, select *provider you want to edit* > *Edit button* > *make the necessary changes* > *Save*.

- (Optional) To change the display name of an existing authentication provider, select the authentication provider whose name you want to change, choose the *Edit icon*, provide the new name, and save your changes.

Configure Authentication Provider To Migrate User Passwords from SAP Concur to Identity Authentication [page 2632]

1.7.18 Configuring OpenID Connect (OIDC)

You can use Identity Authentication for authentication in OpenID Connect (OIDC) protected applications.

OpenID Connect (OIDC) is a simple identity layer on top of the OAuth 2.0 protocol. Clients can verify the identity of the end-user based on the authentication performed by an authorization server, as well as to obtain basic profile information about the end-user in an interoperable and REST-like manner. For more information about the OpenID Connect (OIDC) specification, see OpenID Connect Core 1.0 .

The OpenID Connect (OIDC) implementation of Identity Authentication supports all flow from OpenID Connect (OIDC) Core 1.0.

In addition to the core, the service also supports the following:

- Discovery
- Front-Channel Logout
- OAuth 2.0 Dynamic Client Registration Protocol

Based on your scenario, choose one of the flows to see how to authorize access to your application:

- Using Authorization Code Flow [page 2638]
- Call Identity Authentication Refresh Token [page 2725]
- Using Client Credentials Flow [page 2660]
- Using Resource Owner Password Credentials Flow [page 2669]
- Using Implicit Flow [page 2679]
- Call Identity Authentication Revoke Token Endpoint [page 2736]
- Call Identity Authentication Discovery Endpoint [page 2729]
- Call Identity Authentication UserInfo Endpoint [page 2735]
- Call Identity Authentication Certificate Endpoint [page 2731]
- Call Identity Authentication List Sessions Endpoint [page 2733]
- Call Identity Authentication Introspect Token Endpoint [page 2738]
- Using JWT Bearer Flow [page 2689]
- Call Identity Authentication End Session Endpoint [page 2740]
- Call Identity Authentication Introspect Token Endpoint [page 2738]
- Using Token Exchange [page 2701]
- Call Identity Authentication Revoke Token Endpoint [page 2736]
- Call Identity Authentication List Sessions Endpoint [page 2733]
- Using Token Exchange [page 2701]
- Logging OpenID Connect (OIDC) Tokens [page 2980]

1.7.18.1 Using Authorization Code Flow

To authenticate using the authorization code flow, follow the procedures below. Tasks 1 and 2 are configurations on Identity Authentication side. Tasks 3 and 4 are configurations, done on the client (relying party) side.

> → Recommendation
>
> Follow the best practices of RFC 9700 and use PKCE for confidential clients. You must use PKCE for public clients.

1. Create OpenID Connect (OIDC) Application [page 2639]
   You can create a new OpenID Connect (OIDC) application.
2. Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642]
   This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the authorization code flow.
3. Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow [page 2645]
   The authorize endpoint is used for authentication and returns authorization code when using the authorization code flow. It's recommended for confidential clients that can keep the client secret.
4. Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650]
   The authorization code flow with PKCE is recommended for public clients that aren't capable of keeping the client secrets.

5. Configure the Client to Call Identity Authentication Token Endpoint for Authorization Code Flow [page 2656]
   The token endpoint is used to get the user's access token, id token and refresh token.

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.1.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional.

Fields	Notes
	⚠ Caution If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down.

Fields	Notes
	Note Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]

Task overview: Using Authorization Code Flow [page 2638]

Next task: Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642]

1.7.18.1.2 Configure OpenID Connect (OIDC) Application for Authorization Code Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the authorization code flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (mandatory)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Front-Channel Logout URIs	(Optional) URIs which will be requested for logout. You can add up to 20 URIs.
Back-Channel Logout URI	(Optional) URIs which will be requested for logout. You can add up to 20 URIs.

> ### → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. **→ Tip** To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. **⚠ Caution** The application will stop working if the configuration of the application is not updated with the new certificate.

Option	Description
	Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> **Tip**
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the following grant types:

Grant Type	Notes
Authorization Code	For the authorization code flow.
Authorization Code > *Authorization Code / Enforce PKCE (S256)*	For the authorization code flow with PKCE.

> **Note**
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> **Remember**
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> **Note**
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

Task overview: Using Authorization Code Flow [page 2638]

Previous task: Create OpenID Connect (OIDC) Application [page 2639]

Next: Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow [page 2645]

Handle Single Logout Request from Identity Authentication [page 2743]

1.7.18.1.3 Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow

The authorize endpoint is used for authentication and returns authorization code when using the authorization code flow. It's recommended for confidential clients that can keep the client secret.

This document explains how to call the `authorize` endpoint and what are the authorize request parameters supported by Identity Authentication for the authorization code flow.

> ⓘ Note
>
> Confidential clients are applications that can keep the client secret. These clients are the so-called web applications.

Prerequisites

For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication.

For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Request

URI: `https://<Cloud Identity Services domain>/oauth2/authorize`

> ⓘ Note
>
> The domain part has the following pattern:

`<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Query
`redirect_uri`	Yes	string	• Configure OpenID Connect (OIDC) Application [page 1949] • Redirect URIs, Post Logout Redirect URI Rules [page 2747]	Query
`response_type`	Yes	string	The supported value is `code`.	Query

Parameter	Required	Data Type	Additional Information	Parameter Type
`scope`	Yes	string	The supported values are: • `openid` • `email` • `profile` • `groups` • `offline_access` **Note** The new tokens are independently created from the Identity Authentication Web session. This means that even if a user logs out from Identity Authentication the `refresh_token` will exist in the database until it expires, and can be used to perform the refresh token flow if the user is not present in Identity Authentication with a Web session. Values must be space-delimited parameter, for example: `scope=openid email`.	Query
`state`	Yes	string	Free text.	Query
`app_tid`	No	string	Reserved.	Query

Parameter	Required	Data Type	Additional Information	Parameter Type
`idp`	No	string	The technical name of the corporate identity provider as configured in the administration console for SAP Cloud Identity Services. When a chain of identity providers are allowed for an application via conditional authentication, these parameters enable the client to specify which corporate identity providers are to be used. Identity Authentication uses the `idp` parameter to detect the correct corporate identity providers and redirect the request to them. When there is more than one corporate IdP in the IdP-initiated link, they are separated by comma "`,`" without space between them. For applications that allow authentication with OIDC, use the value **`local`** to override the conditional authentication configuration and authenticate with Identity Authentication instead.	Query
`login_hint`	No	string	The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen. Supported values are the allowed logon identifiers for the users. The options are *User ID*, *Login Name*, and *Email* (For SAML 2.0). For more information, see Configure Allowed Logon Identifiers [page 2146] .	Query
`logout_uri`	No	string	• Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642] • Logout URI Rules [page 2750]	Query
`max_age`	No	integer	Maximum time in seconds since the user was last authenticated. When `max_age` has been reached, the user must re-authenticate.	Query

Parameter	Required	Data Type	Additional Information	Parameter Type
`nonce`	No	string	Free text.	Query
`prompt`	No	string	This parameter enables the client to determine if the user is still present in the current session. Supported values are: • *login* Force reauthentication of the user. • *none* Without user interaction, check if there is an exisiting user session. If there is a session, continue as normal. If there is no session or if the user is forced to authenticate for other reasons, return the error code `login_required`.	Query

Request Example

```
https://my-tenant.ondemand.com/oauth2/authorize?
response_type=code&scope=openid+email&client_id=94ff0b4b0baa45a893c7cd24254b72b7&
state=state&nonce=m-0G6_FaS3Kg&redirect_uri=https://
example.com&login_hint=dona.moore@example.com
```

Response

Response Headers

Header	Description
`code`	The `code` is generated by Identity Authentication and is returned in the URL as a parameter. It must be used when calling the token endpoint. **Note** The parameter can be used within two minutes after it is generated and returned in the URL. It can be used only once.

Response Status and Error Codes

Code	Reason	Description
302 Found	Successful operation.	Additionally provides a URL in the header field Location. **Note** The URL contains `code` necessary for the token endpoint.
400 Bad Request	Missing or wrong parameter	

Response Example

```
Location:
 https://www.example.com/?code=4454554df477w01s34540672dc462e6f0&state=state
```

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.1.4 Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE

The authorization code flow with PKCE is recommended for public clients that aren't capable of keeping the client secrets.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

This document explains how to call the `authorize` endpoint and what are the authorize request parameters supported by Identity Authentication for the authorization code flow with PKCE.

> ### Note
>
> Public clients are applications that aren't capable of keeping the client secret, such as mobile applications, native applications, and single page applications.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/authorize`

> ### Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Query
`code_challenge`	Yes	string	Client created code. **→ Tip** You can use online PKCE generator tools to generate the `code_challenge` values.	Query
`code_challenge_method`	Yes	string	Code verifier transformation method is "S256" or "plain".	Query
`redirect_uri`	Yes	string	• Configure OpenID Connect (OIDC) Application [page 1949] • Redirect URIs, Post Logout Redirect URI Rules [page 2747]	Query
`response_type`	Yes	string	The supported value is `code`.	Query

Parameter	Required	Data Type	Additional Information	Parameter Type
`scope`	Yes	string	Value must be space delimited parameter, for example: `scope=openid email`. The supported values are: • `openid` • `email` • `profile` • `groups` • `offline_access` **Note** The new tokens are independently created from the Identity Authentication Web session. This means that even if a user logs out from Identity Authentication the `refresh_token` will exist in the database until it expires, and can be used to perform the refresh token flow if the user is not present in Identity Authentication with a Web session.	Query
`state`	Yes	string	Free text.	Query
`app_tid`	No	string	Reserved.	Query
`login_hint`	No	string	The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen. Supported values are the allowed logon identifiers for the users. The options are *User ID*, *Login Name*, and *Email* (For SAML 2.0). For more information, see Configure Allowed Logon Identifiers [page 2146] .	Query

Parameter	Required	Data Type	Additional Information	Parameter Type
`logout_uri`	No	string	• Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642] • Logout URI Rules [page 2750]	Query
`max_age`	No	integer	Maximum time in seconds since the user was last authenticated. When `max_age` has been reached, the user must re-authenticate.	Query
`nonce`	No	string	Free text.	Query
`prompt`	No	string	This parameter enables the client to determine if the user is still present in the current session. Supported values are: • *login* Force reauthentication of the user. • *none* Without user interaction, check if there is an exisiting user session. If there is a session, continue as normal. If there is no session or if the user is forced to authenticate for other reasons, return the error code `login_required`.	Query
`refresh_expiry`	No	string	Reduces the expiration of a refresh token. It's useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0, you won't receive a `refresh_token` in response.	Query

Request Example

Request Example (`code_challenge` and `code_challenge_method` are required)

```
https://my-tenant.ondemand.com/oauth2/authorize?

Proof Key for Code Exchange by OAuth Public Clients (IETF)

1.7.18.1.5 Configure the Client to Call Identity Authentication Token Endpoint for Authorization Code Flow

The token endpoint is used to get the user's access token, id token and refresh token.

This document explains how to call the token endpoint and what are the parameters supported by Identity Authentication.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`grant_type`	Yes	string	authorization_code	Request body
`code`	Yes	string	The `code` generated by Identity Authentication in the `authorize` endpoint. It's returned with the response from the `authorize` endpoint. **Note** The `code` parameter can be used within 2 minutes after it generated and returned in the URL. It can be used only once.	Request body
`redirect_uri`	Yes	string	The same URL that has been sent with the authorization request. For more information, see Configure OpenID Connect (OIDC) Application [page 1949].	Request body
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body
`code_verifier`	No	string	Validation value for the `code_challenge`. Required for PKCE.	Request body
`refresh_expiry`	No	string	Reduces the expiry of a refresh token. It is useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0 or less, you won't receive a `refresh_token` in response.	Request body

Parameter	Required	Data Type	Description	Parameter Type
`max_exchange_period`	No	string	You can set a limit on how long the application can exchange user tokens without re-authenticating after having acquired the initial token. The `max_exchange_period` parameter has a numeric value which can be set at between 1 hour and 4320 hours (six months). → Remember If the `max_exchange_period` value is smaller than the configuration defined in token policy, this value overrides the configuration defined in token policy configuration and propagates it once the token is exchanged or refreshed. If the value is bigger, it is ignored and the configuration defined in token policy is taken into consideration. For more information, see Token Policy Configuration for Applications [page 2752]	Request body
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT-based access token. If not set, the current defaults per grant type are used.	Request body
`app_tid`	No	string	Reserved.	Path

Request Example

```
grant_type=authorization_code&client_id=12b52d2c-1q34-5r5t-
a576-75e85asdf523&code=768fsd1206we951236729134fa4a247ee&redirect_uri=https://
www.example.com
```

Request Example with PKCE

```
grant_type=authorization_code&client_id=23q45d2c-1e98-4c7f-
a576-69e85dddb456&code=b1d87f103c9f4c8a936a2f164c8728a0&redirect_uri=https://
www.example.com&code_verifier=e4yAeaa_OLJ-8ZC1sj6JWFqgRK8QR-
egfqG4lQlsy0~NOrjOcVdIpPxPvUEsG1Il1LP76F0MGr4a0miVD2Z84Gn_Lw67BhZ9GQDTF6wN_fUwQtJ
JeN3bnvk7J.Ty6jDi
```

Response

Response Status and Error Codes

Code	Reason	Description
200 OK	Successful operation.	Returns `access_token`, `refresh_token`, and `id_token`. **Note** The `refresh_token` is used to obtain a new `id_token` and `access_token` when the current token becomes invalid or expires. For more information, see Call Identity Authentication Refresh Token [page 2725]. The `id_token` is in the form of a JWT (JSON Web Token) and contains information about the user. The `id_token` is valid for 60 minutes.
400 Bad Request	Missing or wrong parameter.	Returns information about the error.

Response Payload Example

```
{
 "access_token":
"eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9.eyJhdWQiOiIxMmEzNGI1Yy02ZDc4LTl

Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650]

1.7.18.2 Using Client Credentials Flow

To authenticate using the client credentials flow, follow the procedures below. Tasks 1 and 2 are configurations on Identity Authentication side. Task 3 is a configuration, done on the client (relying party) side.

1. Create OpenID Connect (OIDC) Application [page 2660]
   You can create a new OpenID Connect (OIDC) application.
2. Configure OpenID Connect (OIDC) Application for Client Credentials Flow [page 2663]
   This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the client credentials flow.
3. Configure the Client to Call Identity Authentication Token Endpoint for Client Credentials Flow [page 2666]
   The token endpoint is used to get the user's access token.

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.2.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional.

Fields	Notes
	This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]

- Configure an Application's Home URL [page 1937]
- Visit an Application's Web Page [page 1939]
- Configuring User Attributes from the Identity Directory [page 1973]
- Configuring Attributes Based on Flexible Expressions [page 1979]
- Configure Secrets for API Authentication [page 1997]
- Configure Certificates for API Authentication [page 2001]
- Enable or Disable Kerberos Authentication for an Application [page 2556]
- Configure Risk-Based Authentication for an Application [page 2007]
- Configure User Access to the Application [page 2025]
- Authenticating Identity Provider for an Application [page 2065]
- Enable Email Verification [page 2026]
- Configuring Password Policies [page 2223]
- Configuring Privacy Policies [page 2235]
- Configuring Terms of Use [page 2273]
- Display Application Name on Logon Page [page 2033]
- Configure Logo [page 2030]
- Choose and Configure a Branding Style for an Application [page 2035]
- Configure Registration and Upgrade Forms [page 2046]
- Protecting Self-Registration, Upgrade with Phone Verification [page 2050]
- Protecting Application Forms with Google reCAPTCHA [page 2056]
- Configure Identity Federation [page 2614]
- Configure Authentication Request to Corporate IdPs [page 1966]

Task overview: Using Client Credentials Flow [page 2660]

Next task: Configure OpenID Connect (OIDC) Application for Client Credentials Flow [page 2663]

1.7.18.2.2 Configure OpenID Connect (OIDC) Application for Client Credentials Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the client credentials flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party).

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate.

Option	Description
	Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> **Tip**
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

7. Select the *Client Credentials* grant type.

> **Note**
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

8. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> **Remember**
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

1. Configure authentication for the application. For more information about the configuration, see API Authentication [page 1996].
2. Invalidate the tokens that are no longer need. For more information, see Call Identity Authentication Revoke Token Endpoint [page 2736].

Task overview: Using Client Credentials Flow [page 2660]

Previous task: Create OpenID Connect (OIDC) Application [page 2660]

Next: Configure the Client to Call Identity Authentication Token Endpoint for Client Credentials Flow [page 2666]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.2.3 Configure the Client to Call Identity Authentication Token Endpoint for Client Credentials Flow

The token endpoint is used to get the user's access token.

This document explains how to call the token endpoint and what are the parameters supported by Identity Authentication - for a relying party client and system as administrator.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

Request - Relying Party

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`grant_type`	Yes	string	client_credentials	Request body
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT-based access token. If not set, the current defaults per grant type are used.	Request body
`app_tid`	No	string	Reserved	Request body

Request Example

```
grant_type=client_credentials&client_id=12b52d2c-1q34-5r5t-a576-75e85asdf523
```

Request - System as Administrator

> **Note**
>
> Use the received `access_token` to authenticate when accessing the Application Configurations API and Identity Directory API with a system as administrator.

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`grant_type`	Yes	string	client_credentials	Request body
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body

Request Example

```
Client - Relying Party
Request:
grant_type=client_credentials&client_id=12b52d2c-1q34-5r5t-a576-75e85asdf523
```

```
Client - System as Administrator
Request:
grant_type=client_credentials
```

Response

Response Status and Error Codes

Code	Reason	Description
200 OK	Successful operation.	Returns `access_token`.
400 Bad Request	Missing or wrong parameter.	Returns information about the error.

Response Payload Example

```
{
  "access_token":
"eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9.eyJhdWQiOiIxMnM1NHc2YS0xdzU
2LTVlOGItZjI1Ni0wN3YwNXZmZ2IzMTIiLCJzdWIiOiIxMnM1NHc2YS0xdzU2LTVl
```

```
OGItZjI1Ni0wN3YwNXZmZ2IzMTIiLCJpc3MiOiJodHRwczovLzx0ZW5hbnQgSUQ-L
mFjY291bnRzLm9uZGVtYW5kLmNvbSIsImV4cCI6MTU4ODAyNzk3MCwiaWF0IjoxNT
g4MDI0MTEyLCJqdGkiOiIzMDhiYTg5NC0zMGE0LTQ4MDUtYWUzOS1vc2EyYXNkMjU
2ZTIifQ.9IJLkgsKQtYzMRrHUY004X7OJYWI-L8QV1oG42EZ0Kc",
  "token_type": "Bearer",
  "expires_in": 3600
}
}
```

> **Note**
>
> The format of the `issuer` depends on the configuration in the administration console for SAP Cloud Identity Services. For more information, see Tenant OpenID Connect (OIDC) Configurations [page 2117].

Parent topic: Using Client Credentials Flow [page 2660]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.3 Using Resource Owner Password Credentials Flow

To get access using the resource owner password credentials flow, follow the procedures below.

Tasks 1 and 2 are configurations on Identity Authentication. Task 3 is a configuration on the client (relying party).

> **Restriction**
>
> Only corporate identity providers configured with OpenID Connect (OIDC) support this flow.
>
> If you've configured a corporate identity provider for your application, multifactor authentication isn't supported with this flow. For human users we recommend that you use a web-based flow like the authorization code flow.

1. Create OpenID Connect (OIDC) Application [page 2670]
   You can create a new OpenID Connect (OIDC) application.
2. Configure OpenID Connect (OIDC) Application for Resource Owner Password Credentials Flow [page 2673]
   This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the resource owner password credentials flow.
3. Configure the Client to Call Identity Authentication Token Endpoint for Resource Owner Password Credentials Flow [page 2675]

The token endpoint is used to get the user's access token, id token and refresh token.

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.3.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional.

Fields	Notes
	→ Remember Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.

Fields	Notes
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. → Remember Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

Task overview: Using Resource Owner Password Credentials Flow [page 2669]

Next task: Configure OpenID Connect (OIDC) Application for Resource Owner Password Credentials Flow [page 2673]

1.7.18.3.2 Configure OpenID Connect (OIDC) Application for Resource Owner Password Credentials Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the resource owner password credentials flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party).

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Under the *Configure Manually* section provide a name of your choice.
7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

→ Tip

When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *Password*

ⓘ Note

Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

→ Remember

Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

  > ### Note
  >
  > The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

Task overview: Using Resource Owner Password Credentials Flow [page 2669]

Previous task: Create OpenID Connect (OIDC) Application [page 2670]

Next: Configure the Client to Call Identity Authentication Token Endpoint for Resource Owner Password Credentials Flow [page 2675]

1.7.18.3.3 Configure the Client to Call Identity Authentication Token Endpoint for Resource Owner Password Credentials Flow

The token endpoint is used to get the user's access token, id token and refresh token.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

For more information, see API Authentication [page 1996].

This document explains how to call the token endpoint and what are the parameters supported by Identity Authentication.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type
`grant_type`	Yes	string	The supported value is `password`	Request body
`username`	Yes	string	The user identifier.	Request body
`password`	Yes	string	The user password, and the one-time password (OTP) generated by the user's registered device if the application is configured to require two-factor authentication. **Note** If the application requires two-factor authentication, the OTP code must be linked to the password. For example, `password=mypassword123456`.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body
`refresh_expiry`	No	string	Reduces the expiration of a refresh token. It's useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0, you won't receive a `refresh_token` in response.	Request body
`max_exchange_period`	No	string	You can set a limit on how long the application can exchange user tokens without re-authenticating after having acquired the initial token. The `max_exchange_period` parameter has a numeric value which can be set at between 1 hour and 4320 hours (six months). **→ Remember** If the `max_exchange_period` value is smaller than the configuration defined in token policy, this value overrides the configuration defined in token policy configuration and propagates it once the token is exchanged or refreshed. If the value is bigger, it is ignored and the configuration defined in token policy is taken into consideration. For more information, see Token Policy Configuration for Applications [page 2752]	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT based access token. If not set, the current defaults per grant type are used.	Request body
`app_tid`	No	string	Reserved.	Request body
`scope`	No	string	Value must be space delimited parameter, for example: `scope=openid email`. The supported values are: • `openid` • `email` • `profile` • `groups`	Request body

Request Example

```
grant_type=password&username=<user identifier>&password=<user
password>[<otpcode>]
```

Response

Response Status and Error Codes

Code	Result or X-Message Code	Description
200 OK	Successful operation.	Returns `access_token`, `refresh_token`, and `id_token`. **Note** The `refresh_token` is used to obtain a new `id_token` and `access_token` when the current token becomes invalid or expires. For more information, see Call Identity Authentication Refresh Token [page 2725]. The `id_token` is in the form of a JWT (JSON Web Token) and contains information about the user. The `id_token` is valid for 60 minutes.
400 Bad Request	Missing or wrong parameter.	Returns an information about the error.

Code	Result or X-Message Code	Description
401 Unauthorized	Wrong user ID or password parameters passed for the basic authentication. For more information, see Configure Secrets for API Authentication [page 1997].	The authentication of the client (relying party) failed.
	PASSWORD_CHANGE_REQUIRED	When the user must change his or her password before logon.
	INITIAL_PASSWORD_EXPIRED	When the initial password of the user has expired. After the validity of the initial password expires, the user can't log on to the application and must contact the administrator.

> ### Note
>
> The format of the `issuer` depends on the configuration in the administration console for SAP Cloud Identity Services. For more information, see Tenant OpenID Connect (OIDC) Configurations [page 2117].

Parent topic: Using Resource Owner Password Credentials Flow [page 2669]

Previous task: Configure OpenID Connect (OIDC) Application for Resource Owner Password Credentials Flow [page 2673]

1.7.18.4 Using Implicit Flow

To authenticate using the implicit flow, follow the procedures below. Tasks 1 and 2 are configurations on Identity Authentication side. Task 3 is a configuration, done on the client (relying party) side.

> ### Note
>
> For applications such as mobile applications, native applications and single page applications, the authorization code flow with PKCE is recommended. For more information, see Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650].

1. Create OpenID Connect (OIDC) Application [page 2680]
   You can create a new OpenID Connect (OIDC) application.
2. Configure OpenID Connect Application for Implicit Flow [page 2683]
   This document is intended to help you configure an OpenID Connect application in the administration console for SAP Cloud Identity Services for the implicit flow.
3. Configure the Client to Call Identity Authentication Authorize Endpoint for Implicit Flow [page 2686]
   The `authorize` endpoint is used for authentication and returns the `id_token` when using the implicit flow.

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.4.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a

Fields	Notes
	CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on

Fields	Notes
	the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]

- Configure Authentication Request to Corporate IdPs [page 1966]

Task overview: Using Implicit Flow [page 2679]

Next task: Configure OpenID Connect Application for Implicit Flow [page 2683]

1.7.18.4.2 Configure OpenID Connect Application for Implicit Flow

This document is intended to help you configure an OpenID Connect application in the administration console for SAP Cloud Identity Services for the implicit flow.

Prerequisites

You have an OpenID Connect application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> ⓘ Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate.

Option	Description
	Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> **Tip**
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Selct the *Implicit* grant type.

> **Note**
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> **Remember**
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].

Task overview: Using Implicit Flow [page 2679]

Previous task: Create OpenID Connect (OIDC) Application [page 2680]

Next: Configure the Client to Call Identity Authentication Authorize Endpoint for Implicit Flow [page 2686]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.4.3 Configure the Client to Call Identity Authentication Authorize Endpoint for Implicit Flow

The `authorize` endpoint is used for authentication and returns the `id_token` when using the implicit flow.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

This document explains how to call the `authorize` endpoint and what are the request parameters supported by Identity Authentication for the implicit flow.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/authorize`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request
`nonce`	Yes	string	Free text.	Request
`redirect_uri`	Yes	string	One of the valid URIs configured for the application. You can configure up to five URIs. For more information, see Configure OpenID Connect (OIDC) Application [page 1949].	Request
`response_type`	Yes	string	The supported value is `id_token`	Request
`scope`	Yes	string	The supported value is `openid`	Request
`login_hint`	No	string	The `login_hint` parameter helps the user when he or she is known to the service provider (SP). Thus it prevents the user from re-typing the user identifier on the logon or conditional screen. Supported values are the allowed logon identifiers for the users. The options are *User ID*, *Login Name*, and *Email* (For SAML 2.0). For more information, see Configure Allowed Logon Identifiers [page 2146] .	Request
`logout_uri`	No	string	• Create OpenID Connect (OIDC) Application [page 1925] • Logout URI Rules [page 2750]	Request
`max_age`	No	integer	Maximum time in seconds since the user was last authenticated. When `max_age` has been reached, the user must re-authenticate.	Request

Parameter	Required	Data Type	Additional Information	Parameter Type
`prompt`	No	string	This parameter enables the client to determine if the user is still present in the current session. Supported values are: • *login* Force reauthentication of the user. • *none* Without user interaction, check if there is an exisiting user session. If there is a session, continue as normal. If there is no session or if the user is forced to authenticate for other reasons, return the error code `login_required`.	Request
state	No	string	Free text.	Request

Request Example

```
https://my-tenant.ondemand.com/oauth2/authorize?
response_type=id_token&scope=openid&client_id=T000000&state=state&nonce=m-0G6_FaS
3Kg&redirect_uri=https://example.com&login_hint=dona.moore@example.com
```

Response

Response Status and Error Codes

Code	Reason	Description
200 OK	Successful operation.	Additionally provides a URL in the header field Location. **Note** The URL contains `id_token`. The `id_token` is in the form of a JWT (JSON Web Token) and contains information about the user. The `id_token` is valid for 60 minutes.
400	Missing or wrong parameter	

Response Example

```
https://www.example.com/#id_token=eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9.ey

Parent topic: Using Implicit Flow [page 2679]

Previous task: Configure OpenID Connect Application for Implicit Flow [page 2683]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.5 Using JWT Bearer Flow

To authenticate using the JWT Bearer flow, follow the procedures below. Tasks 1 and 2 are configurations on Identity Authentication side. Task 3 is a configuration, done on the client (relying party) side.

The JWT Bearer flow is used for token exchanges from a server application, where the server already has a token. For example:

- To switch for a public client with restricted audience to a confidential client with full audience list
- To authenticate with a token coming from a different identity provider (IdP) to an Identity Authentication token

> → Remember
>
> If the `id_token` is issued by another OpenID Connect provider, like Microsoft Entra ID for example, you must configure that provider as a corporate identity provider in the administration console of Identity Authentication. For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].

1. Create OpenID Connect (OIDC) Application [page 2690]
   You can create a new OpenID Connect (OIDC) application.
2. Configure OpenID Connect (OIDC) Application for JWT Bearer Flow [page 2693]
   This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the JWT bearer flow.
3. Configure the Client to Call Identity Authentication JWT Bearer Token [page 2696]
   With the JWT bearer flow you can use an `id_token` ID from an application which is in the same Identity Authentication tenant, or an external `id_token` whose issuer is trusted by Identity Authentication.

1.7.18.5.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional. **→ Remember** Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the

Fields	Notes
	administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. **→ Remember** Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

Once the application has been created, the system displays the message `Application <name of application> created`.

The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]
- Visit an Application's Web Page [page 1939]
- Configuring User Attributes from the Identity Directory [page 1973]
- Configuring Attributes Based on Flexible Expressions [page 1979]
- Configure Secrets for API Authentication [page 1997]
- Configure Certificates for API Authentication [page 2001]
- Enable or Disable Kerberos Authentication for an Application [page 2556]
- Configure Risk-Based Authentication for an Application [page 2007]
- Configure User Access to the Application [page 2025]
- Authenticating Identity Provider for an Application [page 2065]
- Enable Email Verification [page 2026]
- Configuring Password Policies [page 2223]
- Configuring Privacy Policies [page 2235]
- Configuring Terms of Use [page 2273]
- Display Application Name on Logon Page [page 2033]
- Configure Logo [page 2030]
- Choose and Configure a Branding Style for an Application [page 2035]
- Configure Registration and Upgrade Forms [page 2046]
- Protecting Self-Registration, Upgrade with Phone Verification [page 2050]
- Protecting Application Forms with Google reCAPTCHA [page 2056]
- Configure Identity Federation [page 2614]
- Configure Authentication Request to Corporate IdPs [page 1966]

Task overview: Using JWT Bearer Flow [page 2689]

Next task: Configure OpenID Connect (OIDC) Application for JWT Bearer Flow [page 2693]

1.7.18.5.2 Configure OpenID Connect (OIDC) Application for JWT Bearer Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the JWT bearer flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.

Setting	Description
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *JWT Bearer* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> ⓘ Note
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

Task overview: Using JWT Bearer Flow [page 2689]

Previous task: Create OpenID Connect (OIDC) Application [page 2690]

Next: Configure the Client to Call Identity Authentication JWT Bearer Token [page 2696]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.5.3 Configure the Client to Call Identity Authentication JWT Bearer Token

With the JWT bearer flow you can use an `id_token` ID from an application which is in the same Identity Authentication tenant, or an external `id_token` whose issuer is trusted by Identity Authentication.

> ⚠ Restriction
>
> Token exchange to external tokens is not supported for public clients and is intentionally restricted for security reasons.
>
> If your use case requires external token exchange, use a **confidential client** instead.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

> ⓘ Note
>
> You can't exchange external tokens in a public client.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

Content-Type `application/x-www-form-urlencoded`

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type

`assertion`	Yes	string	**Same tenant ID token:**
			• user identifier:
			  • if "`user_uuid`" claim is provided, it will be used to search the user by user_uuid
			  • otherwise "`sub`" claim will be used, therefore the subject name identifier from the other application will be checked to accordingly search the user in the tenant
			• audience: must contain the client ID of the requested application in "`aud`" claim
			External ID token:
			• user identifier: according to the Subject Name Identifier configuration of the used corporate identity provider, the value of "email" or "sub" claim will be used to search the user by email
			• audience: must contain either the requested Identity Authentication issuer or the client ID of the corporate identity provider in "`aud`" claim
				Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body
`grant_type`	Yes	string	`urn:ietf:params:oauth:grant-type:jwt-bearer`	Request body
`app_tid`	No	string	Reserved.	Request body
`client_secret`	No	string	The client secret configured for basic authentication for the application. For more information, see Configure Secrets for API Authentication [page 1997].	Request body
`max_exchange_period`	No	string	You can set a limit on how long the application can exchange user tokens without re-authenticating after having acquired the initial token. The `max_exchange_period` parameter has a numeric value which can be set at between 1 hour and 4320 hours (six months). **→ Remember** If the `max_exchange_period` value is smaller than the configuration defined in token policy, this value overrides the configuration defined in token policy configuration and propagates it once the token is exchanged or refreshed. If the value is bigger, it is ignored and the configuration defined in token policy is taken into consideration. For more information, see Token Policy Configuration for Applications [page 2752]	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`refresh_expiry`	No	string	Reduces the expiration of a refresh token. It's useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0, you won't receive a `refresh_token` in response.	Request body
`resource`	No	string	Identifies the dependency consumed by the application. The resource parameter is a Uniform Resource Name (URN). For more information, see Consuming APIs from Other Applications [page 2889].	Request body
`scope`	No	string	Value must be space delimited parameter, for example: `scope=openid email`. The supported values are: • `openid` • `email` • `profile` • `groups` • `offline_access` **Note** The new tokens are independently created from the Identity Authentication Web session. This means that even if a user logs out from Identity Authentication the `refresh_token` will exist in the database until it expires, and can be used to perform the refresh token flow if the user is not present in Identity Authentication with a Web session.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT based access token. If not set, the current defaults per grant type are used.	Request body

Request Example

```
POST /oauth2/token
Content-Type: application/x-www-form-urlencoded
grant_type=urn:ietf:params:oauth:grant-type:jwt-bearer&
client_id=c95ad226-fg34-abc6-abc6-6e8a6b9f2442&
client_secret=PASu9/0sTUeUCG1LAYmSQ18Ut0zrfMz&
assertion=eyJraWQiOiJva3JFVVNsbHRIbGlL...hoXvzy2TgmdPS0LlAXA
```

Response

Response Example

```
Content-Type: application/json

{

Parent topic: Using JWT Bearer Flow [page 2689]

Previous task: Configure OpenID Connect (OIDC) Application for JWT Bearer Flow [page 2693]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants

1.7.18.6 Using Token Exchange

To authenticate using the Token Exchange flow, follow the procedures below. Tasks 1 and 2 are configurations on Identity Authentication side. Task 3 is a configuration, done on the client (relying party) side.

The Token Exchange is used, as the name states, for token exchanges. For more information about this flow, see the OAuth 2.0 Token Exchange specification.

1.7.18.6.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional.

Fields	Notes
	→ Remember Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.

Fields	Notes
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. → Remember Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]
- Visit an Application's Web Page [page 1939]
- Configuring User Attributes from the Identity Directory [page 1973]
- Configuring Attributes Based on Flexible Expressions [page 1979]
- Configure Secrets for API Authentication [page 1997]
- Configure Certificates for API Authentication [page 2001]
- Enable or Disable Kerberos Authentication for an Application [page 2556]
- Configure Risk-Based Authentication for an Application [page 2007]
- Configure User Access to the Application [page 2025]
- Authenticating Identity Provider for an Application [page 2065]
- Enable Email Verification [page 2026]
- Configuring Password Policies [page 2223]
- Configuring Privacy Policies [page 2235]
- Configuring Terms of Use [page 2273]
- Display Application Name on Logon Page [page 2033]
- Configure Logo [page 2030]
- Choose and Configure a Branding Style for an Application [page 2035]
- Configure Registration and Upgrade Forms [page 2046]
- Protecting Self-Registration, Upgrade with Phone Verification [page 2050]

- Configure Identity Federation [page 2614]

- Configure Authentication Request to Corporate IdPs [page 1966]

1.7.18.6.2 Configure OpenID Connect Application for Token Exchange

This document is intended to help you configure an OpenID Connect application in the administration console for SAP Cloud Identity Services for the Token Exchange flow.

Prerequisites

You have an OpenID Connect application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > **Note**
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

8. Select the *Token Exchange (RFC 8693)* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> ⓘ Note
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.6.3 Configure the Client to Call Identity Authentication Token Exchange

With the Token Exchange flow you can exchange one token for another. For more information, see OAuth 2.0 Token Exchange .

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

> **Restriction**
>
> Token exchange to external tokens is not supported for public clients and is intentionally restricted for security reasons.
>
> If your use case requires external token exchange, use a **confidential client** instead.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

Content-Type `application/x-www-form-urlencoded`

HTTP Method: *POST*

Request Headers

Request Parameters

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Parameter	Required	Data Type	Additional Information	Parameter Type
`grant_type`	Yes	string	`urn:ietf:params:oauth:grant-type:token-exchange`	Request body
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body
`client_secret`	No	string	The client secret configured for basic authentication for the application. For more information, see Configure Secrets for API Authentication [page 1997].	Request body
`subject_token`	Yes	string	A security token that represents the identity of the party on behalf of whom the request is being made, as stated in the OAuth 2.0 Token Exchange specification.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`subject_token_type`	Yes	string	The type of the security token in the `subject_token`. Allowed values: • `urn:sap:identity:oauth:token-type:saml2-session` • `urn:ietf:params:oauth:token-type:access_token` • `urn:ietf:params:oauth:token-type:refresh_token` • `urn:ietf:params:oauth:token-type:id_token` • `urn:ietf:params:oauth:token-type:jwt` → Tip You can use either a JWT-based access token or an id_token. If you want to exchange a JWT token of a corporate identity provider (IdP), you should do it before an exchange with a JWT bearer token.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`requested_token_type`	No	string	The type of the requested security token. Allowed values for `requested_token_type` parameter: • `urn:ietf:params:oauth:token-type:access_token` • `urn:ietf:params:oauth:token-type:id_token` • `urn:ietf:params:oauth:token-type:saml2` • `urn:sap:identity:oauth:token-type:saml2-header` **Note** The exchange of an OpenID Connect token with SAML 2.0 is possible in two scenarios, depending on the requested token type string: • `urn:sap:identity:oauth:token-type:saml2-header` - 2043039 • `urn:ietf:params:oauth:token-type:saml2` - SAML 2.0 Bearer Assertion Flow for OAuth 2.0 Client	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`resource`	No	string	Identifies the single sign-on scenario you want to consume. To consume the APIs of other applications, enter the provided API names. For more information, see Consuming APIs from Other Applications [page 2889]. **Note** If `resource` parameter is used to consume APIs from other applications, then the returned token is always of type `urn:ietf:params:oauth:token-type:access_token` even if `requested_token_type` is requested for type `id_token`. To exchange a refresh token for an opaque access token in mobile to web application scenarios, enter `urn:sap:identity:sso`. The access token is only valid for five minutes.	Request body
`refresh_expiry`	No	string	Reduces the expiry of a refresh token. It is useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0 or less, you won't receive a `refresh_token` in response.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`max_exchange_period`	No	string	You can set a limit on how long the application can exchange user tokens without re-authenticating after having acquired the initial token. The `max_exchange_period` parameter has a numeric value which can be set at between 1 hour and 4320 hours (six months). → Remember If the `max_exchange_period` value is smaller than the configuration defined in token policy, this value overrides the configuration defined in token policy configuration and propagates it once the token is exchanged or refreshed. If the value is bigger, it is ignored and the configuration defined in token policy is taken into consideration. For more information, see Token Policy Configuration for Applications [page 2752]	Request body
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT-based access token. If not set, the current defaults per grant type are used.	Request body
`app_tid`	No	string	Reserved.	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`scope`	Yes	string	Value must be space delimi-nated parameter, for example: `scope=openid email`. The supported values are: • `openid` • `email` • `profile` • `groups` • `offline_access` **Note** The new tokens are inde-pendently created from the Identity Authentication Web session. This means that even if a user logs out from Identity Authentication the `refresh_token` will exist in the database un-til it expires, and can be used to perform the re-fresh token flow if the user is not present in Identity Authentication with a Web session.	Request body

Examples

Example

Request to exchange an opaque access token for a new token set.

Request

```
POST /oauth2/token
Content-Type: application/x-www-form-urlencoded
grant_type=urn:ietf:params:oauth:grant-type:token-exchange&
client_id=a90ca226sbc34-soc5-dcf6-6k8a6b9f2469&
client_secret=OWSu0/0sSUeUCG1LAYmSQ10Ut0yrfPz&
subject_token=Zjk1YTI3YERzNGZlZmTlNzZjNzk4YTY2ZjdlZjYwMacw&
subject_token_type=urn:ietf:params:oauth:token-type:access_token&
scope=openid
```

Response

```
Content-Type: application/json
```

```
{
    "access_token": "dzEyYTM0YmM2OWZhZnU3NmE3OThzNjZmN3NmNjg3MQ",
    "refresh_token": "s95s27af4fefae76c798a66f7ef9034",
    "issued_token_type": "urn:ietf:params:oauth:token-type:access_token",
    "id_token": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.ey

subject_token_type=urn:ietf:params:oauth:token-type:id_token&
requested_token_type=urn:ietf:params:oauth:token-type:saml2&
resource=urn:sap:identity:application:provider:name:SAML2SSO
```

Response

```
Content-Type: application/json
{
"access_token": "<Base64Url-Encoded-SAML2-Bearer-Assertion>",
"issued_token_type": "urn:ietf:params:oauth:token-type:saml2",
"token_type": "Bearer",
"expires_in": 600
}
```

Example

Request to exchange an opaque `access_token` for an opaque SSO token using the SSO resource flow.

Request

```
https://my-tenant.ondemand.com/oauth2/token?
grant_type=urn:ietf:params:oauth:grant-type:token-exchange&
client_id=a30ca226sbc21-soc5-dcf6-7k8a6b9f24
client_secret=OWSu0/0sSUeUCG1LAYmSQ10Ut0yrfz&
subject_token=Zjk1YTI3YERzNGZlZmTlNzZjNzk4YTY2ZjdlZjYwacw&
subject_token_type=urn:ietf:params:oauth:token-type:access_token&
requested_token_type=urn:ietf:params:oauth:token-type:acces_token&
resource=urn:sap:identity:sso
```

Response

```
Content-Type: application/json
{
"access_token": "MDFmMTNmY2MtMmViMC00ZWI5LWI0YWQtYjlkZjc5NmE1Mz",
"issued_token_type": "urn:ietf:params:oauth:token-type:access_token",
"scope": "openid",
"token_type": "Bearer",
"expires_in": 300
}
```

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants

1.7.18.7 Using SAML 2.0 Bearer Flow

To authenticate using the SAML 2.0 Bearer flow, follow these procedures. Tasks 1 and 2 are configurations on the Identity Authentication side. Task 3 is a configuration on the client (relying party) side.

Use this flow to exchange a SAML assertion from your corporate identity provider for an OAuth token. This flow implements RFC 7522 .

Your implementation must include the following requirements:

- The issuer of the SAML assertion must match the name of a trusted SAML corporate identity provider.
- The SAML audience must specify the Identity Authentication issuer.
  `<saml:Audience>https://<IAS_Issuer>.<domain></saml:Audience>`
- In the `subject` element, the `subjectConfirmation` uses the method `urn:oasis:names:tc:SAML:2.0:cm:bearer`. In this element, `SubjectConfirmationData` specifies the recipient as the Identity Authentication issuer combined with the token path.

  Example

  ```
  <saml:Subject>
      <saml:NameID Format="urn:oasis:names:tc:SAML:1.1:nameid-
  format:emailAddress">my.name@example.com</saml:NameID>
      <saml:SubjectConfirmation
  Method="urn:oasis:names:tc:SAML:2.0:cm:bearer">
          <saml:SubjectConfirmationData NotOnOrAfter="2026-03-24T11:42:49Z"
  Recipient="https://my_issuer.cloud.sap/oauth2/token"/>
      </saml:SubjectConfirmation>
  </saml:Subject>
  ```

1. Create OpenID Connect (OIDC) Application [page 2716]
   You can create a new OpenID Connect (OIDC) application.

2. Configure OpenID Connect (OIDC) Application for SAML 2.0 Bearer Flow [page 2719]
   This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the SAML 2.0 bearer flow.
3. Configure the Client to Call Identity Authentication SAML 2.0 Bearer Token [page 2722]
   In the SAML 2.0 Bearer Token flow, you exchange one token for another. For more information, see RFC 7522 .

1.7.18.7.1 Create OpenID Connect (OIDC) Application

You can create a new OpenID Connect (OIDC) application.

Context

To create a new OpenID Connect (OIDC) application you have to add a new application to the list of applications in Identity Authentication, and set the protocol of the application to OpenID Connect (OIDC).

To create a new OpenID Connect (OIDC) application follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Create* button on the left-hand panel and fill in the information in the dialog box.
4. Provide the following information:

Fields	Notes
Display Name	Required. The display name of the application appears on the logon and registration pages.
Home URL	Optional. Users are redirected to the *Home URL* after activating their accounts, when they are created via a CSV file import or the user registration service of Identity Authentication.
Type	Optional. **⚠ Caution** If the type of the application is not the correct one, the system may change it automatically without a warning.
Parent Application	Optional.

Fields	Notes
	→ Remember Newly created applications with an assigned parent application will inherit all the configurations from the parent except for the `Client ID` and `Secrets`. The inherited configurations will be marked as such. • If you are an administrator with the *Manage Applications* role, the newly created applications can have as parent any of the parent applications in the administration console. Choose the parent application from the list that pops up. • If you are an administrator with authorizations based on policies, you can assign as parent only the application to which you have read or manage applications rights. The applications to which you have read or manage rights are restricted on the basis of the `application.organization` attribute in the policy. Choose the parent application from the list that pops up. For more information about how to assign authorizations based on policies, see Configure Application Authorizations [page 2325].
Organization ID	Optional. This field allows you to group the applications under a specific organization and on the basis of the *Organization ID* to restrict the access to these applications. The *Organization ID* can contain lowercase Latin letters (a-z), numbers (0-9), and the underscore (_) character. It can be up to 255 characters. • If you are an administrator with *Manage Applications* role, the newly created applications by default are in the `global` *Organization ID*. You can change the *Organization ID* during the creation of the new application by entering a new name or later you can edit it. • If your authorizations are based on policies, the newly created applications can take the *Organization ID* of the applications to which you have manage rights on the basis of the `application.organization` attribute in the policy. Choose the allowed *Organization ID* from the drop-down. **ⓘ Note** Applications created either as subscriptions within or with the Identity service of an SAP BTP subaccount receive the *Organization ID* of the application that represents the trust configuration of that subaccount.

Fields	Notes
Protocol Type	Select the *OpenID Connect(OIDC)* radio-button. → Remember Newly created applications with an assigned parent application will inherit the protocol from the parent. To change the protocol, first create the new application and then edit it.

5. Choose *+Create*.

   Once the application has been created, the system displays the message `Application <name of application> created`.

   The newly created application appears on the list with the applications on the left. It is selected and you can set its protocol to OpenID Connect (OIDC).

Next Steps

(Optional) If necessary, configure additional settings for the application. For more information about the supported configurations for the OpenID Connect (OIDC) applications, see the following links:

- Change an Application's Display Name [page 1934]
- Configure an Application's Home URL [page 1937]

Task overview: Using SAML 2.0 Bearer Flow [page 2715]

Next task: Configure OpenID Connect (OIDC) Application for SAML 2.0 Bearer Flow [page 2719]

1.7.18.7.2 Configure OpenID Connect (OIDC) Application for SAML 2.0 Bearer Flow

This document is intended to help you configure an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services for the SAML 2.0 bearer flow.

Prerequisites

You have an OpenID Connect (OIDC) application in the administration console for SAP Cloud Identity Services. For more information, see .

Context

The trust is configured by entering the information manually. You can enter manually the name of the client (relying party), and its redirect URIs.

To configure an OpenID Connect (OIDC) trusted application in the administration console for SAP Cloud Identity Services, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.

5. Under *SINGLE SIGN-ON*, choose *OpenID Connect (OIDC) Configuration*.
6. Manually enter the communication settings negotiated between Identity Authentication and the client.

Setting	Description
Name (mandatory)	Provide a name of your choice.
Redirect URIs (optional)	The redirection URIs to which the response can be sent. You can add up to 20 redirect URIs.
Post Logout Redirect URIs (optional)	The redirection URIs where the user can be forwarded after logout. You can add up to 20 redirect URIs.
Front-Channel Logout URIs (optional)	URIs which will be requested for logout. You can add up to 20 URIs.

> → Tip
>
> For more information about the format of the redirect URIs and post logout redirect URIs, see OpenID Connect (OIDC) Application Configurations [page 2747].

7. Select the *SAML 2.0 Bearer (RFC 7522)* grant type.

> ⓘ Note
>
> Beware that for each flow the respective grant type must be selected. All other grant types can be deselected if they aren't required by the application.

8. **Optional:** (If you have added signing certificates in *Tenant Settings* or an application certificate in *Applications*.) Under *Identity Provider Certificates*, choose the certificate to be used when a request to the application is signed.

Option	Description
ON	This is the default setting. When the option is enabled, the certificate that is set as *Default* in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates* is used when a request to the application is signed.
OFF	When this option is disabled, the certificate that is set as *Active* in the list is used when a request to the application is signed. You can choose the active certificate from the list. → Tip To add an application certificate for the specific application, go to *Applications* > *choose the application you want to edit* > *Single Sign-On* > *OpenID Connect Configuration* > *Certificates* > *Add*. ⚠ Caution The application will stop working if the configuration of the application is not updated with the new certificate. ⓘ Note Your choice of *Active* certificate in the list is not related with the choice of *Default* certificate in *Tenant Settings* > *Single Sign-On* > *OpenID Connect Configuration* > *Signing Certificates*.

For more information, see Rotate Signing Certificates for OpenID Connect Applications [page 2113].

> → Tip
>
> When the default signing certificate is changed to a new one, and the old one isn't used anymore, we recommend you delete the old certificate.

9. Save your selection. Once the application has been changed, the system displays the message `Application <name of application> updated`.

> → Remember
>
> Configure trust on the client side. See the client documentation for more information about how to configure the trust.

Next Steps

- Configure HTTP basic authentication for the application. For more information about the configuration, see Configure Secrets for API Authentication [page 1997].
- Enable the public client flows option for this application. In the administration console, choose *the OpenID Connect (OIDC) application* > *Client Authentication under the Trust tab* > *Enable Public Client Flows under Public Client*. Optionally, you can configure the API permission groups. For more information, see Consuming APIs from Other Applications [page 2889] .

> ⓘ Note
>
> The *Public* client type is used for environments where it is difficult to protect the client credential, such as mobile and desktop applications, and client-side parts of web applications.

Task overview: Using SAML 2.0 Bearer Flow [page 2715]

Previous task: Create OpenID Connect (OIDC) Application [page 2716]

Next: Configure the Client to Call Identity Authentication SAML 2.0 Bearer Token [page 2722]

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.7.3 Configure the Client to Call Identity Authentication SAML 2.0 Bearer Token

In the SAML 2.0 Bearer Token flow, you exchange one token for another. For more information, see RFC 7522 .

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

Content-Type `application/x-www-form-urlencoded`

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Additional Information	Parameter Type
`assertion`	Yes	string	Enter a Base64URL-encoded SAML assertion.	Request body
`client_id`	Yes	string	Enter the identifier for the Identity Authentication application. **Note** This parameter is optional if the request uses authentication.	Request body
`grant_type`	Yes	string	`urn:ietf:params:oauth:grant-type:saml2-bearer`	Request body
`app_tid`	No	string	The parameter is reserved.	Request body
`client_secret`	No	string	Enter the client secret for basic authentication. For more information, see Configure Secrets for API Authentication [page 1997].	Request body
`max_exchange_period`	No	string	Set a limit for how long the application can exchange user tokens without re-authenticating after the initial token is acquired. You select a numeric value between one hour and 4320 hours (six months). **→ Remember** If the `max_exchange_period` value is smaller than the configuration in token policy, the value overrides the token policy configuration and applies when the token is exchanged or refreshed. If the value is larger, the system ignores it and uses the existing token policy configuration. For more information, see Token Policy Configuration for Applications [page 2752].	Request body

Parameter	Required	Data Type	Additional Information	Parameter Type
`refresh_expiry`	No	string	Reduces the expiration of a refresh token. It's useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0, you won't receive a `refresh_token` in response.	Request body
`resource`	No	string	Enter the Uniform Resource Name (URN) for the dependency used by the application. For more information, see Consuming APIs from Other Applications [page 2889].	Request body
`scope`	No	string	Parameter values must be space-delimited. For example: `scope=openid email`. Supported values: • `openid` • `email` • `profile` • `groups` • `offline_access` **Note** Tokens are created independently from the Identity Authentication web session. Even if a user logs out from Identity Authentication, the `refresh_token` remains in the database until it expires. You can use it for the refresh token flow if the user doesn't have an active session in Identity Authentication.	Request body
`token_format`	No	string	You can set `token_format` to `opaque` to retrieve an opaque access token, or to `jwt` to retrieve a JWT-based access token. If you don't set the parameter, the system uses the current defaults for each grant type.	Request body

Request Example

```
POST /oauth2/token
Content-Type: application/x-www-form-urlencoded
grant_type=urn:ietf:params:oauth:grant-type:saml2-bearer&
client_id=c95ad226-fg34-abc6-abc6-6e8a6b9f2442&
client_secret=PASu9/0sTUeUCG1LAYmSQ18Ut0zrfMz&
assertion=PHNhbWw6QXNzZXJ0aW9uIElEPSJB...1sOkFzc2VydGlvbj4=
```

Response

Response Example

Parent topic: Using SAML 2.0 Bearer Flow [page 2715]

Previous task: Configure OpenID Connect (OIDC) Application for SAML 2.0 Bearer Flow [page 2719]

1.7.18.8 Call Identity Authentication Refresh Token

The refresh token is used to receive a new id token and access token, to be used when the old token is not valid or expires.

To get an id token or access token via the refresh token for the first time the client must have a refresh token received via either the authorization code flow or the resource owner password credentials flow. For more information, see Call Identity Authentication Refresh Token [page 2725], or Configure the Client to Call Identity Authentication Token Endpoint for Resource Owner Password Credentials Flow [page 2675]. Once the client has a valid refresh token it can be used to call the token endpoint to receive a new id token and access token.

Prerequisites

- For your business application, there's an OpenID Connect (OIDC) application in Identity Authentication. For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OpenID Connect (OIDC) application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
    For more information, see `Authorization` in the *Request Header* table below.
  - X.509
    For more information, see `Authorization` in the *Request Header* table below.
  - JWT (client_assertion)
    - Trust by issuer: You must include the `client_id` in the request.
    - Trust by URI: Including `client_id` in the request is optional.

    For more information, see the *Request Parameters* table below.

  For more information, see API Authentication [page 1996].

Request

URI: `https://<Cloud Identity Services domain>/oauth2/token`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`grant_type`	Yes	string	refresh_token	Request body

Parameter	Required	Data Type	Description	Parameter Type
`refresh_token`	Yes	string	The `refresh_token` generated by Identity Authentication in the token endpoint of the supported flows. It is returned with the request to the token endpoint. If `token_format` was specified in `grant_type` before, for example `authorization_code`, this format is re-used in the refresh token endpoint. **Note** The validity of the `refresh_token` after it is generated and returned in the URL is the same as timeout session for Identity Authentication. For more information about the session timeout feature, see Configure Session Timeout [page 2170].	Request body
`refresh_expiry`	No	string	Reduces the expiration of a refresh token. It's useful if your application is called from mobile and web applications, and both have different session requirements. If you set the token lifetime to 0, you won't receive a `refresh_token` in response.	Request body
`token_format`	No	string	The `token_format` can be set to `opaque` to retrieve an opaque access token or to `jwt` to retrieve a JWT based access token. If not set, the current defaults per grant type are used.	Request body
`app_tid`	No	string	Reserved.	Request body

Request Example

```
grant_type=refresh_token&refresh_token=d12a12abcd198765dd54r456e98321
```

Response

Response Status and Error Codes

Code	Reason	Description
200 OK	Successful operation.	Returns `access_token`, `refresh_token`, and `id_token`. The `id_token` is valid for 60 minutes.
400 Bad Request	Missing or wrong parameter.	Returns an information about the error.
401 Unauthorized	Wrong user ID or password parameters passed for the basic authentication. For more information, see Configure Secrets for API Authentication [page 1997].	The authentication of the client (relying party) failed.

1.7.18.9 Call Identity Authentication Discovery Endpoint

This document explains how to call the discovery endpoint.

OpenID Connect Discovery enables clients to verify the identity of the end user based on the authentication performed by Identity Authentication.

Call Discovery Endpoint

URI: `https://<Cloud Identity Services domain>/.well-known/openid-configuration`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`appid`	No	string	Used to identify the corresponding Identity Authentication application.	Request body
`app_tid`	No	string	Reserved.	Request body
`client_id`	No	string	Used to identify the corresponding client of the Identity Authentication application.	Request body

Request Examples

```
https://my-tenant.ondemand.com/.well-known/openid-configuration
```

Result

Result

```

```

> **Note**
>
> The format of the `issuer` depends on the configuration in the administration console for SAP Cloud Identity Services. For more information, see Tenant OpenID Connect (OIDC) Configurations [page 2117].

> **Restriction**
>
> - If the `issuer` doesn't use HTTPS, then this tenant isn't OIDC-compliant. Not using HTTPS can cause integration failures. Changing the protocol at the tenant level can also cause integration failures. You can change the protocol at the application level to make the issuer OIDC compliant for that application. In the *OpenID Connect Configuration* of the application, set *Enforce Compliant OIDC Issuer*.
> - If *Enforce Compliant OIDC Issuer* is enabled, you must provide one of the following parameter combinations in your discovery endpoint request:
>   - `client_id` and optional `app_tid`
>   - `appid`
>
>   Without one of these parameter combinations, the discovery endpoint returns an issuer URL without the protocol, which causes OIDC validation to fail.

> **→ Remember**
>
> Identity Authentication supports only the assertion created by the security token service (STS) model. For more information, see OAuth Assertion Framework .

1.7.18.10 Call Identity Authentication Certificate Endpoint

The certificate endpoint contains information about the OpenID provider public keys.

The public keys are encoded as JSON Web Key (JWK).

Request

URI: `https://<Cloud Identity Services domain>/oauth2/certs`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/json
`x-app_tid`	No	Reserved.
`x-client_id`	No	Reserved.

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`appid`	No	string	Used to identify the corresponding Identity Authentication application.	Request body
`app_tid`	No	string	Reserved.	Request body

Parameter	Required	Data Type	Description	Parameter Type
client_id	No	string	Used to identify the corresponding the client of the Identity Authentication application.	Request body

Request Example

```
https://my-tenant.ondemand.com/oauth2/certs
```

Response

Response Status and Error Codes

Code	Description
200	Success

Response Payload Example

JSON Web Key (JWK)

1.7.18.11 Call Identity Authentication List Sessions Endpoint

The service endpoint returns the list of sessions associated with the OpenID Connect (OIDC) token submitted with the request. Use this endpoint to enable your application to see how many tokens are still active after the application has performed a token exchange.

> **Note**
>
> The result is similar to when the authenticated user looks at their sessions and tokens in their user profile. For an example, view the self-service application.
>
> 1. Navigate to `https://<my_tenant>.sap.com/ui/protected/profilemanagement`.
> 2. Under *Sessions and Tokens*, choose *Show*.

Prerequisites

- For your business application, there's an OIDC application in Identity Authentication.
  For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- For your OIDC application in Identity Authentication, you've prepared an authentication credential for the API call. The API supports the following authentication schemes:
  - Basic
  - X.509
  - JWT Bearer

  For more information, see API Authentication [page 1996].
- Your application has an access, ID, or refresh token.

Call Session List Endpoint

URI: `https://<Cloud Identity Services domain>/oauth2/token/list`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`token`	Yes	string	Provide the Identity Authentication token. The endpoint supports ID tokens, access tokens, and refresh tokens.	Request body
`client_id`	No	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is mandatory if the request is provided without authentication.	Request body

Request Example

```
POST /oauth2/token/list
Content-Type: application/x-www-form-urlencoded
Authorization: Basic eyJbiOi…

token=eyJ0eab…
```

Result

The result is an array of sessions for the user associated with token your application submitted.

```
Content-Type: application/json

```

Related Information

Configuring OpenID Connect (OIDC) [page 2636]

1.7.18.12 Call Identity Authentication UserInfo Endpoint

OpenID Connect UserInfo endpoint enables the clients to retrieve information about the authenticated user.

The client makes a request to the UserInfo endpoint using the access token obtained from the OpenID Connect authentication from the user-based flows.

Request

URI: `https://<Cloud Identity Services domain>/oauth2/userinfo`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET* or *POST*

Request Headers

Header	Required	Values
`Authorization`	Yes	Bearer <access_token>

Request Example

```
GET /oauth2/userinfo
  Host: https://<tenant ID>.accounts.ondemand.com
  Authorization: Bearer eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9
```

Response

Response Status and Error Codes

Code	Reason	Description
200	Successful operation.	Returns information about the user.
400	Bad request	Returns an error with error description. For example, expired token.
401	Unauthorized	The client is not authenticated.
403	Forbidden	Returns an error with error description.

Response Example

```
{
 "aud": "a123456e-314a-4923-899c-05c535c3d7f9",
 "sub": "P12345",
 "user_uuid": "158a1b2c7-981az-69ab9-8079-d824da69c681",
 "mail": "dona.moore@example.com",
 "iss": "https://my-_tenant.accounts.ondemand.com",
 "last_name": "Moore",
 "exp": 1588019044,
 "iat": 158801376,
 "first_name": "Dona",
 "jti": "38e42330-de7a-4130-a3a1-b582b528da98"
}
```

1.7.18.13 Call Identity Authentication Revoke Token Endpoint

The revoke token endpoint invalidates any access and refresh tokens issued to the client for the same end-user and session.

To revoke tokens from other sessions belonging to the same end-user, find the other session and revoke tokens for those sessions separately. For more information about finding user sessions, see Call Identity Authentication List Sessions Endpoint [page 2733].

The token revocation endpoint is implemented according to RFC 7009 OAuth 2.0 Token Revocation .

Request

URI: `https://<Cloud Identity Services domain>/oauth2/revoke`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded
`Authentication`	Yes	• Basic Authentication - Client ID and a Secret to authenticate the client (relying party). For more information, see Configure Secrets for API Authentication [page 1997]. **Note** The client ID and secret must be encoded using the "application/x-www-form-urlencoded" encoding algorithm. • X.509 Certificate • Bearer `<client_credential_token>`)

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`token`	Yes	string	Must contain the JWT or opaque token from the issuer.	Path
`token_type_hint`	No	string		Path
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided with authentication.	Request body

Request Example

```
token=0ab12345978c51ffe7c4e9a2b1158bb4
```

Response

Token is successfully revoked.

Response Status and Error Codes

Code	Reason
200 OK	Successful operation.
401 Unauthorized	The client is not authenticated.

1.7.18.14 Call Identity Authentication Introspect Token Endpoint

The introspect token endpoint is an option for clients to get long expiring refresh tokens, opaque access and id tokens in JWT format validated.

The introspect token endpoint is implemented according to RFC 7662 OAuth 2.0 Token Introspection .

Request

URI: `https://<Cloud Identity Services domain>/oauth2/introspect`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Header	Required	Values
`Authorization`	Yes	• Basic - Client ID and a Secret to authenticate the client (relying party). For more information, see Configure Secrets for API Authentication [page 1997]. **Note** The client ID and secret must be encoded using the "application/x-www-form-urlencoded" encoding algorithm. • Bearer <client_credential_token>) • X.509 Certificate

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`token`	Yes	string	Must contain the JWT or opaque token from the issuer.	Request body
`token_type_hint`	No	string		Request body
`client_id`	Yes	string	Used to identify the corresponding Identity Authentication application. **Note** The `client_id` parameter is optional if the request is provided without authentication.	Request body

Request Example

```
token=0ab82505123c12ffe7c4e9a2b0158cn7
```

Response

Response Example

If token is valid:

```
Content-Type: application/json
{
 "active": true,
 "aud": "a123456e-314a-4923-899c-05c535c3d7f9",
 "username": "P12345",
 "sub": "P12345",
 "user_uuid": "158a1b2c7-981az-69ab9-8079-d824da69c681",
 "mail": "dona.moore@example.com",
 "iss": "https://my-_tenant.accounts.ondemand.com",
```

```
 "last_name": "Moore",
 "exp": 1588019044,
 "iat": 158801376,
 "first_name": "Dona",
 "jti": "38e42330-de7a-4130-a3a1-b582b528da98"
}
```

If token is not valid/expired/not known or any other token related issue:

```
Content-Type: application/json
{
 "active": false
}
```

Response Status and Error Codes

Code	Reason
200 OK	Successful operation.
401 Unauthorized	The client is not authenticated.

1.7.18.15 Call Identity Authentication End Session Endpoint

To propagate a user's logout to other applications and any corporate identity providers used, an OIDC application can call the end session endpoint of Identity Authentication.

After the entire single logout (SLO) operation has completed, by default, Identity Authentication redirects the user agent to the Identity Authentication profile page of the user. To redirect the user after logout to a different page of the application that triggered the logout, include a post logout URI in your request. The URI must be among the allowed post logout redirect URIs configured for the application.

For more information, see OpenID Connect (OIDC) Application Configurations [page 2747].

If you include a post logout redirect URI in your request, include the client ID. Instead of including the client ID, you can include the ID token and the service reads the client ID from the token.

Call End Session Endpoint

URI: `https://<Cloud Identity Services domain>/oauth2/logout`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`id_token_hint`	No → Remember The parameter is optional, but either `id_token` or `client_id` must be present.	string	Previously issued `id_token`. **Note** The token must be from the current session.	Query
`post_logout_redirect_uri`	No	string	The redirection URI where the user will be forwarded after logout.	Query
`state`	No	string	Used by the application to maintain state between the logout request and the callback to the endpoint specified by the `post_logout_redirect_uri` query parameter. If included in the logout request, the identity provider passes this value back to the application using the `state` query parameter when redirecting the browser back to the application.	Query

Parameter	Required	Data Type	Description	Parameter Type
`client_id`	No → Remember The parameter is optional, but either `id_token` or `client_id` must be present.	string	Used to identify the corresponding Identity Authentication application.	Query
`app_tid`	No	string	Required for multitenant scenarios to identify corresponding Identity Authentication application.	Query

> ### Note
>
> All request parameters can be combined in any order.

```

```
https://my-tenant.ondemand.com/oauth2/logout?
post_logout_redirect_uri=https%3A%2F%2Fexample.com&client_id=a0b22cd0-
f2d5-45d8-9937-3a4bebd6598c
```

```
https://my-tenant.ondemand.com/oauth2/logout?state=state&client_id=a0b22cd0-
f2d5-45d8-9937-3a4bebd6598c
```

Result

Response Status and Error Codes

Identity Authentication terminates all user sessions and finally redirects the user to the post logout page.

1.7.18.16 Handle Single Logout Request from Identity Authentication

When a user logs out from an application, the other applications that participate in the same user session must also be notified, so that it can log out the user as well. The application that doesn't trigger the logout, but must be notified, should do the following:

- Provide your own logout endpoint. For more information, see OpenID Connect Front-Channel Logout 1.0 .
- Configure the endpoint (*Front-Channel Logout URIs* or *Back-Channel Logout URIs*) in the respective Identity Authentication application. For more information, see Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642] or Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650].

> **Note**
>
> If the application is a multitenant one, it must include the tenant-specific logout endpoint during the login flow. This endpoint must follow the rules, specified in Logout URI Rules [page 2750]. The logout endpoint is sent during login (see Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow [page 2645] or Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650]).

1.7.18.17 Claims of SAP Cloud Identity Services OAuth Tokens

Understanding OAuth token claims helps you to achieve secure and efficient authentication and authorization. This knowledge helps you use tokens correctly, reduce security risks, and maintain trust in your system.

Viewing Claims Supported by SAP Cloud Identity Services

View the claims issued by SAP Cloud Identity Services by calling the discovery endpoint and checking the `claims_supported` property.

URI: `https://<Cloud Identity Services domain>/.well-known/openid-configuration`

For more information, see Call Identity Authentication Discovery Endpoint [page 2729].

Supported Claims

The following table describes the claims supported by SAP Cloud Identity Services.

Claims Supported by SAP Cloud Identity Services

Claim	Description
`app_tid`	An SAP claim that identifies the tenant of the application. This claim is used in multitenant scenarios, for example, if you subscribed to a SAP BTP application.
`at_hash`	This claim contains a hash of the access token. Clients can hash the access token that it received and compare it to the `at_hash` value in the ID token to ensure they belong together and prevent token substitution attacks.
`aud`	Identifies the recipient of the token. It can be a string or array of audience identifiers, such as the client ID of the application requesting access.
`auth_time`	This claim shows the time when the client authenticated, in seconds since the Unix epoch in UTC. Applications can use this claim to determine how long ago a user authenticated and to enforce reauthentication.
`azp`	The authorized party identifies the client ID to which the ID token was issued.

Claim	Description
`azpacr`	An SAP claim that identifies the authentication context class reference of the authorized party. It indicates the strength of authentication used by the client application when it obtained the token. A value of `1` indicates the client used a client secret, and a value of `2` indicates the client used a certificate. This claim is present in tokens issued through the client credentials grant type.
`azp_app_tid`	An SAP claim that identifies the tenant of the authorized party in app-to-app token exchange scenarios. In multitenant SAP BTP environments, this claim represents the application tenant identifier of the consumer application that initiated the token exchange. The `app_tid` claim represents the provider application's tenant.
`cnf`	Binds a token to a specific cryptographic key held by the client. In proof-of-possession token scenarios, only the client holding the corresponding private key can use the token.
`email`	Email address of the user for whom the token was issued. This claim is included when the `email` scope is requested.
`email_verified`	Indicates whether or not the email has been verified. It's a boolean. This claim is included when the `email` scope is requested.
`exp`	The expiration time after which the token must not be accepted.
`family_name`	The surname (last name) of the user for whom the token was issued. This claim is included when the `profile` scope is requested.
`given_name`	The given name (first name) of the user for whom the token was issued. This claim is included when the `profile` scope is requested.
`groups`	The groups the user belongs to. These groups are associated with authorizations. This claim is included when the `groups` scope is requested.
`ias_apis`	An SAP claim that lists the API permission groups or a fixed value for when all APIs of an application are consumed. They're used to make authorization decisions. See also Consuming APIs from Other Applications [page 2889].
`ias_iss`	An SAP claim that identifies an SAP tenant even if the token was issued from a custom domain in a non SAP domain.

Claim	Description
`iat`	The time when the token was issued in seconds of the Unix epoch. Used to determine the age of the token.
`iss`	Identifies the issuer of the token. Typically a URL, for example, `https://<tenant>.accounts.ondemand.com`.
`jti`	A unique identifier for the JWT. Used to avoid replay attacks.
`middle_name`	Middle name of the user for whom the token was issued.
`name`	Full display name of the user for whom the token was issued.
`nonce`	A string associated with the client session to help mitigate against replay attacks. Clients can verify that it matches was the client sent in its authentication request.
`preferred_username`	A human-readable display name for the user for whom the token was issued. The claim shows what the user recognizes as their username.
`sap_azp_gtid`	An SAP claim that provides a globally unique tenant identifier of the authorized party in app-to-app token exchange scenarios. In multitenant SAP BTP environments, this claim represents the globally unique tenant identifier of the consumer application that initiated the token exchange.
`sap_gtid`	An SAP claim that provides a globally unique tenant identifier.
`sap_intospect`	An SAP claim that holds a list of claim names that were omitted from the token due to size restrictions. You can retrieve the full values of these claims from the `/oauth2/userinfo` or `/oauth2/introspect` endpoint.
`sap_id_type`	An SAP claim that identifies the type of token. Values: • `app`: The token is a credential for an application. • `user`: The token is a credential for a user.
`sap_scope`	An SAP claim that lists the scopes granted to the token. Currently, only the `offline_access` scope is stored in this claim.
`sap_user_type`	An SAP claim that identifies the type of user for whom the token was issued.
`scim_id`	An SAP claim that identifies the user with their SCIM ID in SAP Cloud Identity Services.

Claim	Description
`sid`	The session ID is used to track the session of a user with that specific application.
`sub`	The subject is a unique identifier for the user for whom the token is issued. Identity Authentication rejects a token request when the subject claim of the token matches the client ID of the requesting Identity Authentication application.

1.7.18.18 OpenID Connect (OIDC) Application Configurations

Redirect URIs, Post Logout Redirect URI Rules [page 2747]
Rules for the redirect URIs or post logout redirect URIs.

Logout URI Rules [page 2750]
Rules for the front and back-channel URIs.

Token Policy Configuration for Applications [page 2752]
Set the token policy for a specific OpenID Connect application. Configure the validity of the refresh token, access and id_token, and the maximum sessions per user.

Configure Grant Types [page 2755]
Configure the allowed grant type for your OpenID Connect application.

1.7.18.18.1 Redirect URIs, Post Logout Redirect URI Rules

Rules for the redirect URIs or post logout redirect URIs.

The redirect URI defines the redirection URIs to which the response can be sent. The post logout redirect URI defines the redirection URIs where the user can be forwarded after logout.

The redirect URI or post logout redirect URI must be in the following format:

`protocol://domain<:port>/<path>`

For example: `https://example.com:70/path`.

> ⓘ Note
>
> The URL parameters are not taken into consideration during runtime.

When you construct the redirect URIs or post logout redirect URIs have the following in mind:

Number

You may have a maximum of 20 redirect URIs and 20 post logout redirect URIs.

Length

The length is limited to 499 characters.

Domains

Top level domains are allowed. The domain part can't end with a hyphen "-".

- Protocols - Use the HTTPS protocol. The HTTP protocol is only allowed for localhost.

  > ✤ Example
  >
  > https://example.com
  >
  > https://10.11.12.13

- Localhost is allowed in the domain part.

  > ✤ Example
  >
  > http://localhost
  >
  > https://localhost
  >
  > http://127.0.0.1
  >
  > https://127.0.0.1

- Non-ascii characters are not allowed in the domain part.
- Custom schemas are supported, except `ftp`, `sftp`, `tftp`, `file`, `telnet` and `http`.
  Custom schemas must have at least 2 characters. The following are allowed: lower case characters, numbers, and the special characters "`.`", "`-`", and "`+`" .

  > ✤ Example
  >
  > custom-schema://example

Wildcards

- You can use asterisk (*) as first subdomain for localhost addresses. No other subdomains allowed.

  > ✤ Example
  >
  > http://*.localhost
  >
  > https://*.localhost

- You can use asterisk (`*`) in the domain part, or you can have a subdomain and add an asterisk at the beginning or at the end of it. There must be at least 3 subdomains left after the subdomain with the asterisk, and there can only be one subdomain with an asterisk.

> ### Example
>
> https://*.test.example.com
>
> https://app.*foo.test.example.com
>
> https://app.foo*.test.example.com

- You can use asterisk (`*`) at the end of the path, or between paths.

  > ### Example
  >
  > https://example.com/path/*
  >
  > https://example.com/path/*/path2

- You can use double wildcard, two asterisks (`**`), at the end of a path.

  > ### Example
  >
  > https://example.com/**
  >
  > http://localhost/path/*/path2/**

Ports (optional)

After the domain you can specify a port number, always preceded by a leading colon (`:`).

> ### Example
>
> https://example.com:8080

We support port wildcards for `localhost` and IP address `127.0.0.1` in redirect URIs of OIDC applications. Port wildcards enable tools, such as ABAP Development Tools, which use variable ports.

> ### Restriction
>
> Port wildcards aren't supported for other hosts.

> ### Example
>
> ```
> http://localhost:*
> https://localhost:*
> https://localhost:*/some/path
> http://*.localhost:*
> http://127.0.0.1:*/some/path
> https://127.0.0.1:*/some/path
> ```

Parent topic: OpenID Connect (OIDC) Application Configurations [page 2747]

Related Information

Logout URI Rules [page 2750]
Token Policy Configuration for Applications [page 2752]
Configure Grant Types [page 2755]

1.7.18.18.2 Logout URI Rules

Rules for the front and back-channel URIs.

Identity Authentication triggers a logout request to the front or back-channel URI.

The front and back-channel logout URI must be in the following format:

`protocol://domain<:port>/<path><?query parameters>`

For example: `https://example.com:70/logout?abc=123`.

When you construct the front and back-channel URIs, have the following in mind:

Number

You may have a maximum of 20 front and 20 back-channel URIs.

Length

The length is limited to 499 characters.

Domains

- Protocols - Use the HTTPS protocol. The HTTP protocol is only allowed for localhost.

  > ✤ Example
  >
  > https://example.com/logout

- Localhost - It's allowed in the domain part.

> **Example**
>
> http://localhost/logout
>
> https://localhost/logout

- Wildcard - It's allowed in the domain part. Wildcards are only supported in front-channel flows. Although there's no restriction on using wildcards with single tenant apps, the use of wildcards was developed with multitenant applications in mind. When using wildcards, the `logout_uri` parameter is required.

  > **Example**
  >
  > https://*.example.com/logout
  >
  > Allow during authorize call to register a URI with parameter `logout_uri`, for example: `https://app1.example.com/logout`.

- IP Addresses - Usage of IP addresses isn't allowed.

Ports (optional)

After the domain part, you can put the port numbers. Always use a leading colon (`:`).

> **Example**
>
> https://example.com:8080/logout

Fragments

> **Restriction**
>
> Usage of fragment identifier (#) isn't allowed. For example, you can't use `https://example.com/path#index.html`.

1.7.18.18.3 Token Policy Configuration for Applications

Set the token policy for a specific OpenID Connect application. Configure the validity of the refresh token, access and id_token, and the maximum sessions per user.

Context

Token Policy

The following table lists the token policy options for OIDC applications.

Token Policy Configuration Parameters

Parameter	Description

Refresh Token	Sets the refresh token lifetime issued by Identity Authentication. The value can range from 1 to 4320 hours, in other words, from 1 hour to 180 days.
	
	The default value is 12 hours.
	
	Note
	• If the validity of refresh tokens is less than the validity of access/ID tokens, access/ID tokens can't be refreshed after the access/ID tokens expire.
	• When using the authorization code flow, if you set the token policy for refresh tokens longer than the session timeout, add the *offline_access* scope to your authorization code request. Without this scope, the service deletes the refresh token from the database when the resource owner ends the session (logs out). Without the refresh token, the OAuth client can't request new tokens anymore. For more information, see:
	  • Configure Session Timeout [page 2170]
	  • Using Authorization Code Flow [page 2638]

Access / ID Token	Sets the access and id_token lifetime issued by Identity Authentication. The value can range from 1 to 720 minutes, in other words, from 1 minute to 12 hours. The default value is 60 minutes.

Parameter	Description
Max sessions per user	Determines the maximum number of tokens that the service issues for the same session in parallel. Imagine you're logged on to the application through a web interface and a command-line interface in parallel. Then you'd set this parameter to 2. The value can range from 1 to 10. The default value is 1.

> → Remember
>
> The default configurations for the token policy per application are the tenant token policy. If you configure new values for an application, the service ignores the tenant token policy for that application. For more information about the tenant token policy, see Tenant OpenID Connect (OIDC) Configurations [page 2117]

> ⓘ Note
>
> The effective token validity for OIDC applications cannot exceed the Global Session Timeout configured at the tenant level. If the session timeout is shorter than the token policy values configured here, access tokens are capped at the remaining session duration, and refresh tokens cannot be renewed beyond session expiry. Exchanging a refresh token does not extend the session. For more information, see Configure Session Timeout [page 2170].

Offline Access

Disable this option to stop users from using this application beyond the regular session validity. You can configure this only for source applications. It is turned off by default. This control isn't visible for single-tenant applications and is enabled by default. Use this option to enable users to access a mobile or native application, such as a command-line interface, without having to authenticate each time.

Enforce Reauthentication

Use this option to limit how long the application can refresh user tokens without reauthenticating. This function helps you meet compliance requirements that restrict tokens from being valid beyond a specific period. By default this option is enabled and set to 3 months. When enabled, the maximum possible value is 2,147,483,647 seconds.

Advanced Settings

Refresh Token Usage After Renewal

When refresh token flows fail, you can enable the server to accept a refresh token that was already submitted. Normally, a refresh token can only be used once. The configuration aims to solve issues, for example network problems in refresh token calls, and allow an application to retry this call. Define the behavior of clients depending on your scenario and the risk. If you extend the rotation life time, we recommend revoking existing tokens with a separate call.

Refresh Token Usage After Renewal

Settings	Description
Off (Default)	The new refresh token immediately invalidates the old one.

Settings	Description
Online scenarios	The new refresh token is created and the old one is still active for 5 minutes.
Mobile scenarios	The new and old refresh token are valid during the configured refresh token life time.

> **Note**
>
> For online and mobile scenarios, calls to refresh the old refresh token end in the new token. Calls with the new refresh token, invalidates the old refresh token.

Access Token Format

Settings	Description
Grant-Type Dependent (Default)	The format of the token depends on the grant type. It is as folows: • Authorization Code Flow - `JWT` • Client Credentials Flow - `JWT` • Resource Owner Password Credentials Flow - `opaque` • Token Exchange - `opaque` • JWT Bearer Flow - `opaque` • Refresh Token Endpoint - `opaque`
JSON Web Token	All tokens are generated in the JWT format.
Opaque	All tokens are generated in the opaque format.

Enforce Compliant OIDC Issuer

If you notice this configuration option in your application, the default configuration of the tenant issuer is not OIDC compliant. This configuration can cause your application to

- Fail OIDC discovery.
- Fail token validation in standard libraries.
- Be unable to interoperate with other OIDC-compliant systems.

When enabled, the issuer of tokens for this application always starts with "`https://`".

To configure an application-specific token policy, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Single Sign-On*, choose *OpenID Connect Configuration*.
6. Under the *Authentication* tab, choose *Authentication Policy (`<Default or Custom>`)*.
7. Choose *Edit*.
8. Configure the token policy for the application.

   If needed, use the reset button to set to the default value.
9. **Optional:** Choose values for the *Advanced Settings* configuration.
10. Save your changes.

Task overview: OpenID Connect (OIDC) Application Configurations [page 2747]

Related Information

Redirect URIs, Post Logout Redirect URI Rules [page 2747]
Logout URI Rules [page 2750]
Configure Grant Types [page 2755]
Tenant OpenID Connect (OIDC) Configurations [page 2117]

1.7.18.18.4 Configure Grant Types

Configure the allowed grant type for your OpenID Connect application.

Prerequisites

You have an OpenID Connect application in the administration console for SAP Cloud Identity Services. For more information, see Create OpenID Connect (OIDC) Application [page 1925].

Context

To configure the grant type, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *OpenID Connect Configuration*.
6. Configure the allowed grant types for the application.

Grant Type	Default Behavior
Authorization Code	selected
Authorization Code / Enforce PKCE (S256)	not-selected
Password	selected
JWT Bearer	selected
Implicit	not-selected
Refresh	selected
Client Credentials	selected
Token Exchange (RFC 8693)	not-selected

> **Note**
>
> Beware that for each flow the respective grant type must be selected.

7. Save your selection.

   Once the application has been changed, the system displays the message `Application <name of application> updated`.

Task overview: OpenID Connect (OIDC) Application Configurations [page 2747]

1.8 User Guide

This user guide describes the scenarios in the Identity Authentication from a user's perspective. It's aimed at consumers, partners, and employees.

For the scenarios, users can use services to maintain or update their user profiles and to log on to applications. User services are divided into profile and sign-on services. For configuration of certain profile services, users access the profile page.

> **Note**
>
> You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

Users can use the following sign-on services:

- Basic authentication
  Users can log on to applications by providing basic credentials, such as user name and password.
- Single Sign-On authentication
  Users can access cloud applications via SAML 2.0 or OpenID Connect based single sign-on (SSO).
- Multi-factor authentication
  If the application requires second factor for authentication, users should provide an SMS code, or a passcode generated by a mobile device as an addition to the basic authentication. For more information, see Multi-Factor Authentication [page 2761].

Users can use the following self-services:

On the Logon Page

- Self-registration
  If this option is activated by an administrator, a user can register when he or she accesses the application's logon page. When the user clicks on the *Register* button, a registration form appears, where he or she needs to provide some personal data. The user also has to accept the organization's terms of use and privacy policy.
  By clicking the *Register* button, the users acknowledge that he or she has read the organization's privacy policy document.
  Once the user has submitted the form, he or she receives an email explaining how to activate the account. Successful activation of the user account completes the registration, thus allowing the user to log on to the application.

  > **Note**
  >
  > If the user hasn't received the activation email, he or she can do the following:

- Check the *Deleted*, *Junk*, or other folders in his or her mail box.
- Follow the *Forgot Password* link in the logon page of the application. If the registration is successful, this will trigger the *Forgot Password* process, and the user will receive an email with instructions how to reset the password.
- Choose the *Register Now* link, and fill in the registration form again.
- Contact the system administrator of the application.

- Forgot password
  A user can change his or her password when he or she accesses the application's logon page. When the user clicks on the *Forgot password?* link, the user triggers the forgot password process.
- Social sign-on
  If this feature is enabled by an administrator, users can link their Identity Authentication accounts with social network accounts. That way they can authenticate through a social provider by choosing the social network button on the logon page. They can also unlink their accounts on the profile page.

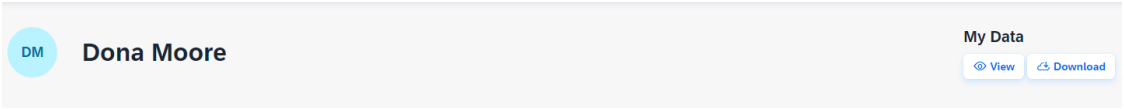
> ### Note
>
> The content in this section is not relevant for China (Shanghai) region.

On the Profile Page

- Changing profile data
  Users can change their profile information on the profile page. This includes Personal Information, Company Information, and Contact Preferences.

> ### Note
>
> The `Login Name` field can't be edited on the profile page. This field can be edited by the tenant administrator via the administration console for SAP Cloud Identity Services.
>
> The `Valid From` and `Valid To` fields are empty if no validity dates are set for the user. The dates are not editable via the profile page.

- Viewing profile data
  - Users can open a printable overview of all the data on file for them by visiting their account information in the upper right corner of the screen and choosing the *User Data* section from the menu.



> ### Note
>
> The data includes the **Terms of Use** and **Privacy Policy** documents singed by the user. The documents can be seen by clicking on their names. They open in a new tab.

  - Users can download an overview of all the data for them on a JSON file by clicking the download button in the *User Data* section.
- Self verifying user phone
  The phone verification possibility on the Profile Page is optional and must be enabled by a system administrator.
  If phone verification is enabled by a system administrator, the users provide their phone number in the respective field, after that they receive an SMS code and enters it in the provided field to complete the

verification. Once the phone number is verified, users can change it on the profile by choosing *Edit* in the *Personal Information* section. They will receive a verification code on the phone which must be provided so that the change is completed. If the code fails to arrive, users have up to five attempts to request a new code via SMS. They can also trigger one phone call per session.
When CAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) protection is enabled, users must solve the CAPTCHA to verify their phone.
If the phone number is not verified, users can change it without a verification code.

> ⚠ Restriction
>
> A phone number can be verified by only one user. If another user has already verified the phone number that is provided, the user is prompted to choose a different one or contact an administrator.

- Changing user passwords
  Users can change their passwords on the profile page.
  By clicking the change password button in the *Password* section, users trigger the change password process. That way, they are asked to provide the current and the new passwords. Users must also comply with the password requirements.

  > ⓘ Note
  >
  > Users must familiarize themselves with the password policy for logging on to the respective application. If no password policy is set for the application, users are able to modify their passwords with any characters of their choosing.

- Viewing sessions and tokens information
  Users can view their sessions and tokens on the profile page and delete those that they don't want or they don't trust. There is information about the:
  - browser
  - operating system
  - IP address
  - credentials or token type
  - expiration period
- Unlinking social sign-on
  Users can unlink their accounts on the profile page.

  > ⓘ Note
  >
  > The content in this section is not relevant for China (Shanghai) region.

1.8.1 Passwordless Authentication

This document provides information about the passwordless authentication option.

Based on the configurations for the application, you may authenticate with a certificate or biometric information (something that you are) without the need to provide your username and password.

FIDO2 Biometric Authentication

If biometric authentication is allowed for the application, you can choose the *Biometric Authentication* button on the logon page. If you have a configured FIDO2 biometric authentication device, the logon process will require authentication with the registered device. If biometric authentication isn't configured, you are required to register a device by providing your username and password first. This is a one time configuration.

> **Note**
>
> You can add more than one device via your profile page, but you can't add a device that has already been added, either for biometric authentication or for two-factor authentication.
>
> You can also remove a device from the list on the profile page. The removal of a device is password protected.

Identity Authentication supports the following:

Device	OS	Browser
Face ID	Latest iOS	• Latest Chrome • Latest Safari
Touch ID	Latest macOS	• Latest Chrome • Latest Safari
Windows Hello	Windows 10	• Latest Edge • Latest Chrome

Certificate Authentication

If certificate authentication is allowed for the application, you can generate your own certificate and authenticate with it without the need to provide your username and password.

When certificate authentication is allowed, you can see the *Certificates* section on your profile page. You should go to the profile page and under the *Certificates* section generate your certificate for authentication. You must provide your user password, then the certificate password, and the certificate validity. You can choose from 12 months, three months, and one month.

Once the certificate is generated, it's downloaded to your device. Import the certificate to your certificate store, and it is ready for authentication. Now, when you navigate to the logon page of the application, you

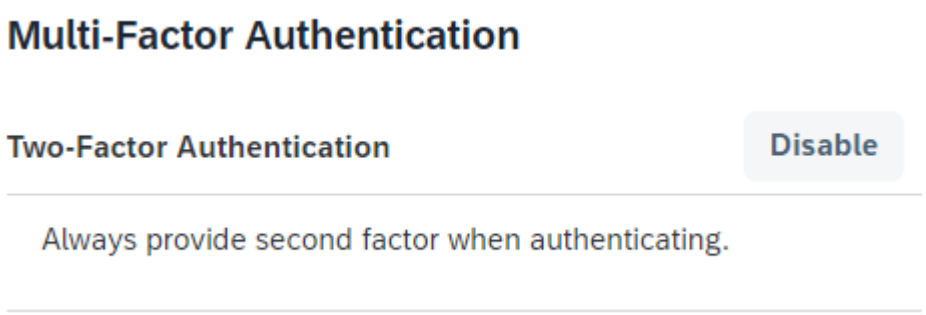
are automatically authenticated with the certificate. If the authentication fails, you're prompted to provide username and password.

1.8.2 Multi-Factor Authentication

This document provides information about the second factor for authentication or how to sign in if you are asked to provide a second factor to your primary credentials.

Based on the configurations for the application, you can be asked to provide a time-based, one time (TOTP) passcode, generated on a mobile device, a one-time (OTP) passcode sent to your email, a passcode sent via SMS, or a PIN security key. You can choose one of the enabled second factor authentication methods or press the button to enable a new method.

You can also choose to enhance your security with a second factor, although the application may not explicitly require it. This choice is available only if the system administrator has allowed it for your profile. If enabled, you see the following option on the profile page:



For more information about this option, see Always Authenticate with Second Factor [page 2763].

Authenticate with TOTP Two-Factor Authentication

TOTP passcodes are time-based and are valid for one logon attempt only, thus providing additional security to the common static passwords. Passcodes are generated by an authenticator application. The authenticator is a mobile application that you install on your mobile devices. For more information about how to install and configure authenticators, see their documentation.

To sign in when the application requires TOTP two-factor authentication, first you provide your primary credentials, choose the method or enable it, then provide the passcode generated on your mobile device.

If you don't have a device, activated for TOTP two-factor authentication, see Activate TOTP Two-Factor Authentication [page 2765].

Authenticate with SMS Two-Factor Authentication

SMS passcodes are sent to a mobile device.

To sign in when the application requires SMS two-factor authentication, first you provide your primary credentials, choose the method, or enable it, then you provide the passcode you received via SMS.

Authenticate with Web Two-Factor Authentication

To sign in when the application requires web authentication (FIDO2 standard), first you provide your primary credentials, choose the method, or enable it, then you provide the PIN code on your security key hardware USB authenticator. If you don't have a registered security key, you must register it first.

If you don't have a device activated for web authentication, see Add a Device for Web Two-Factor Authentication [page 2766].

Authenticate with Email Two-Factor Authentication

To sign in when the application requires email two-factor authentication, first you provide your primary credentials, choose the method, or enable it, then enter the 8-digit code sent to your email. You can request a new code after 3 minutes from your last request.

> → Remember
>
> Your session is valid for 10 minutes. If you don't use the code within the ten-minute period, the session expires and you must provide your primary credentials, and enter the new 8-digit code sent to your email again.

If you enter five wrong codes in row, the email two-factor authentication will be temporarily locked because of too many failed sign in attempts. It will be automatically unlocked in 60 minutes. If the application allows other two-factor authentication methods, you can use them.

If your email is not verified, the system won't send you a code, and you must contact the application's administrator for assistance.

Always Authenticate with Second Factor [page 2763]
: This document provides information about how to enhance the security of your account by always providing second factor in addition to your primary credentials.

Activate TOTP Two-Factor Authentication [page 2765]
: To log on to applications that require time-based one-time password (TOTP) as two-factor authentication, first you have to activate a mobile device that will generate TOTP passcodes.

Add a Device for Web Two-Factor Authentication [page 2766]
: To log on to applications that require web two-factor authentication (FIDO2 standard), first you have to activate an authenticator device.

Deactivate TOTP Two-Factor Authentication [page 2768]
: This document shows you how to deactivate the TOTP two-factor authentication that you use to access applications requiring passcodes for stronger authentication.

Remove Web Two-Factor Authentication [page 2770]
: This document shows you how to remove the web two-factor authentication (FIDO2 standard) that you use to access applications requiring it for stronger authentication.

1.8.2.1 Always Authenticate with Second Factor

This document provides information about how to enhance the security of your account by always providing second factor in addition to your primary credentials.

Prerequisites

You have a device activated for time-based one-time password (TOTP) or Web Two-Factor Authentication. For more information, seeActivate TOTP Two-Factor Authentication [page 2765] and Add a Device for Web Two-Factor Authentication [page 2766].

Context

You can choose to enhance your security with additional authentication, second factor (passcode or security key), although the application may not explicitly require it. This option is available only if the system administrator has allowed it for your profile.

> **Note**
>
> If the option is allowed by the administrator, but you don't have an activated device, you won't be able to enable it. When the option is disabled, but you dont't have on the profile page, under *Multi-Factor Authentication*, you see:
>
> >
>
> To use this option you must first activate a device for time-based one-time password (TOTP) or Web Two-Factor Authentication.

To enable the *Multi-Factor Authentication* option, proceed as follows:

Procedure

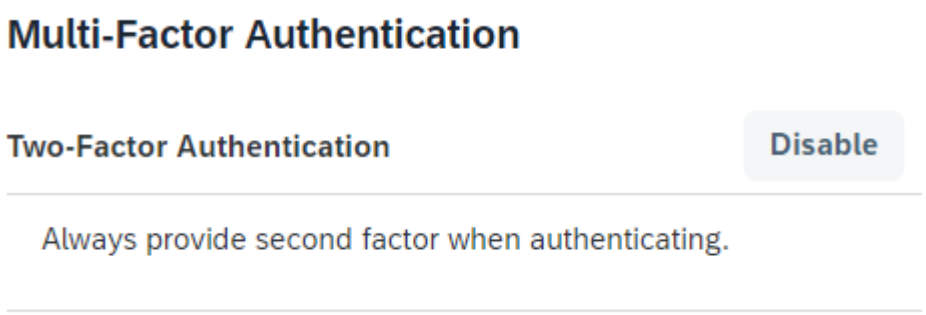
1. Access your profile page.

> **Note**
>
> You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Under *Multi-Factor Authentication*, enable *Two-Factor Authentication* to always provide second factor when authenticating.
3. Verify your identity if you have already activated multi-factor authentication.

Results

When enabled, you see the following option on your profile page:



Next Steps

Activate multifactor authentication methods. For more information, see Activate TOTP Two-Factor Authentication [page 2765] or Add a Device for Web Two-Factor Authentication [page 2766].

Task overview: Multi-Factor Authentication [page 2761]

Related Information

Activate TOTP Two-Factor Authentication [page 2765]
Add a Device for Web Two-Factor Authentication [page 2766]
Deactivate TOTP Two-Factor Authentication [page 2768]
Remove Web Two-Factor Authentication [page 2770]

1.8.2.2 Activate TOTP Two-Factor Authentication

To log on to applications that require time-based one-time password (TOTP) as two-factor authentication, first you have to activate a mobile device that will generate TOTP passcodes.

Prerequisites

- You have installed a QR code scanner and an authenticator application on your mobile device.

  > **Note**
  >
  > You can use third-party authenticators such as Google Authenticator or Microsoft Authenticator. For more information about how to install and configure the authenticators see their documentation.

Context

Some applications require two-factor authentication as an additional security to the common static passwords. They will ask you to provide your password and a passcode, generated by a mobile device.

> **Note**
>
> Passcodes are only necessary for applications that require two-factor authentication. You do not need to activate a device for applications that only require passwords for authentication.

You activate a mobile device that generates passcodes.

Procedure

1. Access your profile page.

   > **Note**
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Under the *Multi-Factor Authentication* section, choose *Activate* for *TOTP Two-Factor Authentication*.
3. Open the authenticator application.
4. Provide your security key and follow the onscreen instructions on the profile page.

   > **Note**
   >
   > Skip this step if you activate two-factor authentication for the first time.

5. Do one of the following on your mobile device:
    - Scan the QR code from the profile page screen.
    - Enter the secret key from the profile page screen manually.
6. Complete the setup on your mobile device.
7. Enter the passcode generated by the authenticator application in the space provided on the screen on your profile page.
8. Press *Activate*.

Results

Now, you can log on to applications that require passcode as an additional security for authentication.

> **Note**
>
> Optionally, you can activate TOTP two-factor authentication when you log on to an application that requires passcode as a second factor. Access the protected page of the application and follow the onscreen instructions.

Task overview: Multi-Factor Authentication [page 2761]

Related Information

Add a Device for Web Two-Factor Authentication [page 2766]
Deactivate TOTP Two-Factor Authentication [page 2768]
Remove Web Two-Factor Authentication [page 2770]

1.8.2.3 Add a Device for Web Two-Factor Authentication

To log on to applications that require web two-factor authentication (FIDO2 standard), first you have to activate an authenticator device.

Prerequisites

- Use a browser and platform that supports web authentication.

Context

Some applications require web two-factor authentication as an additional security to the common static passwords. They ask you to authenticate to the application and use your device to continue the logon.

> **Note**
>
> You can add more than one device for web two-factor authentication.

Procedure

1. Access your profile page.

   > **Note**
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Press plus button next to *Web Two-Factor Authentication*.
3. Verify your identity by choosing a verification method and follow the onscreen instructions.

   > **Note**
   >
   > Skip this step if you activate two-factor authentication for the first time.

TOTP Two-Factor Authentication	(if configured) Provide the passcode and choose *Send* after selecting that option.
WEB Two-Factor Authentication	(if configured) Your security key. Follow the onscreen instructions after selecting that option.

4. Choose *Activate* and follow the instructions.

   Connect your authenticator device if not connected.
5. In the popup, allow the site to see the make and model of your security key.
6. Provide a name for your device.

Results

Now, you can log on to applications that require web authentication as an additional security for authentication.

> **Note**
>
> Optionally, you can activate a web two-factor authentication when you log on to an application that require it as a second factor. Access the protected page of the application and follow the onscreen instructions.

Task overview: Multi-Factor Authentication [page 2761]

Related Information

Always Authenticate with Second Factor [page 2763]
Activate TOTP Two-Factor Authentication [page 2765]
Deactivate TOTP Two-Factor Authentication [page 2768]
Remove Web Two-Factor Authentication [page 2770]

1.8.2.4 Deactivate TOTP Two-Factor Authentication

This document shows you how to deactivate the TOTP two-factor authentication that you use to access applications requiring passcodes for stronger authentication.

Context

You can deactivate TOTP two-factor authentication if you don't want to use it anymore to generate passcodes.

If you deactivate the TOTP two-factor authentication, you won't be able to log on to applications that require only passcodes. To be able to access these applications again, you have to activate again TOTP. For more information, see Activate TOTP Two-Factor Authentication [page 2765].

> → Tip
>
> If your device that generates passcodes has been lost or stolen, or you can't provide a valid passcode, you can still deactivate the TOTP via the channels offered on the profile page, or contact a system administrator of the application.

Based on the configuration of the account made by the administrator, you can choose among three deactivation channels:

- *Existing Multi-Factor Authentication* - to verify your identity, choose a verification method:
  - *TOTP Two-Factor Authentication* - use a passcode generated on your registered device
  - (if configured) *WEB Two-Factor Authentication* - provide security key
- *Passcode via SMS* - (if configured) use a passcode sent to you on your verified phone
- *Passcode via Email* - (if configured) use a passcode sent to you on your verified email

> ⚠ Caution
>
> The system can send you up to three emails within 24 hours. After that you won't be able to request a passcode for TOTP deactivation via email during these 24 hours.

To deactivate your mobile device that generates passcodes, proceed as follows:

Procedure

1. Access your profile page.

   > **Note**
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Press the deactivate button next to *TOTP Two-Factor Authentication*.
3. Select a deactivation channel:

Existing Multi-Factor Authentication	Choose one of the verification methods: • *TOTP Two-Factor Authentication* - This is the default choice. Provide the passcode and choose *Send* after selecting that option. • *WEB Two-Factor Authentication* - Your security key (if configured.). Follow the onscreen instructions after selecting that option.
Passcode via SMS	Provide the passcode and choose *Send* after selecting that option.
Passcode via Email	Provide a passcode and choose *Send* after selecting that option.

   > **Note**
   >
   > The deactivation channels depend on the configuration of the account made by the administrator. You may not see all deactivation channels.

4. Press *Deactivate*.

Task overview: Multi-Factor Authentication [page 2761]

Related Information

Remove Web Two-Factor Authentication [page 2770]

1.8.2.5 Remove Web Two-Factor Authentication

This document shows you how to remove the web two-factor authentication (FIDO2 standard) that you use to access applications requiring it for stronger authentication.

Context

You can remove web two-factor authentication if you don't want to use it anymore to verify your identity.

> **Note**
>
> If you remove the web two-factor authentication, you won't be able to log on to applications that require it as additional authentication. To be able to access these applications again, you have to activate again web authentication. For more information, see Add a Device for Web Two-Factor Authentication [page 2766].

Based on the configuration of the account made by the administrator, you can choose among three channels:

- *Existing Multi-Factor Authentication* - choose a verification method:
  - (if configured) *TOTP Two-Factor Authentication* - use a passcode generated on your registered device
  - *WEB Two-Factor Authentication* - provide security key
- *Passcode via SMS* - (if configured) use a passcode sent to you on your verified phone
- *Passcode via Email* - (if configured) use a passcode sent to you on your verified email

> **Caution**
>
> The system can send you up to three emails within 24 hours. After that you won't be able to request a passcode for TOTP deactivation via email during these 24 hours.

To remove your mobile device that generates passcodes, proceed as follows:

Procedure

1. Access your profile page.

   > **Note**
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Under *Web Two-Factor Authentication*, press the delete button next to the device that you want to remove.
3. Select a channel:

Existing Multi-Factor Authentication	Choose one of the verification methods:

	• *TOTP Two-Factor Authentication* - Provide the pass-code and choose *Send* after selecting that option. • *WEB Two-Factor Authentication* - This is the default choice. Your security key (if configured.). Follow the onscreen instructions after selecting that option.
Passcode via SMS	Provide the passcode and choose *Send* after selecting that option.
Passcode via Email	Provide a passcode and choose *Send* after selecting that option.

> ⓘ Note
>
> The deactivation channels depend on the configuration of the account made by the administrator. You may not see all deactivation channels.

4. Press *Remove* if required.

Task overview: Multi-Factor Authentication [page 2761]

1.8.3 Social Authentication

Context

> ⓘ Note
>
> The content in this section is not relevant for China (Shanghai) region.

Log on with a Social Provider Account

You can log on to applications that use Identity Authentication via your accounts in X, Facebook, LinkedIn, or Google.

Prerequisites

The applications must be configured to allow logon via social networks.

Context

Using the social network authentication, you link your Identity Authentication account with your social network account or accounts. After the initial setup, when you link the accounts, you can log on to the applications with your social network credentials.

Identity Authentication has access to the following data from the social providers:

Social Identity Provider	Data Used by Identity Authentication
Apple	ID of your user - used to link your Apple account with your Identity Authentication account
Facebook	• ID of your user - used to link your Facebook account with your Identity Authentication account • your display name - used to prefill the registration form in case of non-existing user
Google	• ID of your user - used to link your Google account with your Identity Authentication account • your display name, first name, and last name - used to prefill the registration form in case of non-existing user
LinkedIn	• ID of your user - used to link your LinkedIn account with your Identity Authentication account • your first name and last name - used to prefill the registration form in case of non-existing user
X	• ID of your user - used to link your X account with your Identity Authentication account • your display name - used to prefill the registration form in case of non-existing user • your logon name

This data is used for the initial linking of your Identity Authentication account with the social network account. Later, if you update the personal information in your social account, the updated information will not be copied by Identity Authentication.

To link your Identity Authentication account with a social network account, proceed as follows:

Procedure

1. Access the application's logon page.
2. Choose the icon of the social network provider you want to log on with.

   > ### Note
   >
   > Which social networks are displayed on the page depends on the application.

3. Sign in to your social network account.
4. Choose one of the following options:
   - Link your Identity Authentication account with your social network account.
   - Create a new Identity Authentication account that will be linked with your social network account.

     > ### Note
     >
     > This option appears only for applications that allow user registration.

Results

Once you allow Identity Authentication to link your account with the social providers' accounts, you can log on to the applications via the social providers.

Unlink a Social Provider Account

You can unlink your social provider account via the profile page.

Context

To remove your social network logon information from your Identity Authentication account, proceed as follows:

Procedure

1. Access the profile page.

   > ### Note
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Press *Edit* under *Social Sign-On*.
3. Press *Unlink* to remove your social network logon information from your account.

   If the operation is successful, the system displays the message Profile updated .

1.8.4 Use the Remember Me Option

With the *Remember me* functionality enabled, you can log on to an application without the need to provide your credentials every time you access it.

Context

If you enable the *Remember me* functionality, the application saves a cookie in the browser on your local computer. It automatically logs you on next time you access the application from the same browser on your local computer. Once enabled, the *Remember me* functionality is valid for 3 months unless you log out from the application.

> ### Note
>
> If the application requires two-factor authentication, you must provide a valid one-time password (passcode) generated by a mobile device every time you access the application. For more details about how to use two-factor authentication on your mobile device, see **Related Information**.

Procedure

1. Access the application that you want to log on to with *Remember me*.
2. Provide your credentials and select the *Remember me* checkbox.
3. **Optional:** Provide a passcode if required.

Results

Next time you access the application, you will be logged on automatically. If the application requires two-factor authentication, you need to provide a valid passcode, generated by a mobile device.

> ⓘ Note
>
> If you want to disable *Remember me* for an application log out from the application, and do not select the checkbox next time you log on.

> → Remember
>
> If you are authenticating with credentials from an external system (authentication provider or corporate user store), the following limitations are observed:
>
> - (in the case of corporate user store) when you are authenticating with remember me cookie, your cloud user record in Identity Authentication is not updated.
> - (in the case of authentication provider or corporate user store) if you change your password in the external system, the remember me cookie is not invalidated.
>
> For more information about the type of your system, contact your system administrator.

> → Remember
>
> If you are authenticating with credentials from an external authentication provider, if you change your password in the external provider, the remember me cookie is not invalidated.
>
> For more information about the type of your provider, contact your system administrator.

Related Information

Multi-Factor Authentication [page 2761]

1.8.5 Change or Reset Password via Profile Page

You, as an end-user, can change your current password or request a reset password email via your profile page.

Context

Your password grants you access to any platform connected to Identity Authentication. Depending on the configuration of your profile page, you can either change your password directly on the profile page or request a reset password email via your profile page. The configuration is done by an administrator, and you can't choose which option to use.

To change your current password, you need to provide the current and the new passwords to the system. To reset your password, you must have access to your email. You can find information about the email of your account in the *Personal Information* section of your profile page. For both cases you must comply with the password requirements.

> → Tip
>
> If you don't know your current password, follow the *Forgot Password* link at the sign-in page of the application. This triggers the **Forgot Password** process, and receive an email with instructions how to reset your password. For more information, see Reset Your Forgotten Password [page 2777].
>
> If you don't see the *Forgot Password* link at the sign-in page, contact the system administrator of your application.

To change or reset your current password, follow the procedure below:

Procedure

1. Access your profile page.

   > ⓘ Note
   >
   > You have received the link to your profile page in an email with information how to activate your account for user profile. If you can't find this email, and you don't know how to access your profile page, please contact your system administrator for assistance.

2. Under *Authentication*, you see only one of the following options in the *Password* section:
   - *Change* - When you press the *Change* button, a pop-up requiring input from you appears. Provide your current and new password and save your changes. If the operation is successful, you sign in with your new password.
   - *Reset* - When you press the button *Reset* an email is sent to your inbox. To reset your password, click on the link that is in the email, provide the new password on screen that appears, and save your changes. If the operation is successful, you can sign in with your new password.

Results

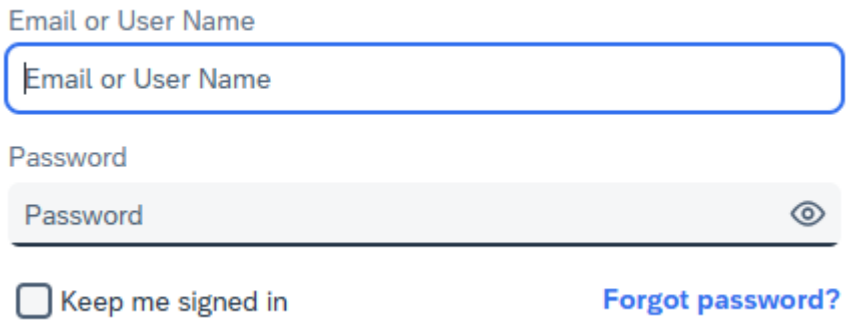
> → Remember
>
> Your password can only be changed once every 24 hours.

1.8.6 Reset Your Forgotten Password

You can reset your password if you have forgotten it.

Prerequisites

- You have forgotten your current password.
- You see the *Forgot Password* link on the sign-in page of your application:



> ⓘ Note
>
> The image is just for an illustration purpose and may differ from your sign-in page.

Some applications don't offer the reset password option. If you can't see the *Forgot Password* link, contact the system administrator of your application with a request to reset your password.

Context

> → Tip
>
> If you know your password, but for security or any other reasons you want to change it, follow the procedure in Change or Reset Password via Profile Page [page 2776].

If you don't remember your current password, choose the *Forgot Password* link in the sign-in page of the application, and follow the onscreen instructions. Depending on the configurations made by your organization, you may have one, two, or all three options:

- Receive an email with instructions how to reset your password.
- Answer security questions. You must have already configured your answers in the profile page to be able to reset password via this option.
- Provide a PIN code. You must have already set your PIN code in the profile page to be able to reset the password via this option.

Passwords can be reset and changed once in 24 hours.

To reset your password, follow the steps below:

Procedure

1. Access the sign-in page of the application.
2. Choose the *Forgot Password* link.
3. Choose one of the options available on your screen. Be aware that the options are visible only if the application supports them:
   - **Optional:** *Email* - Provide the email address from your account and press *Continue*. An email with a link to a page where you can reset your password will be sent to you. The email might take a few minutes to reach your inbox.

     > → Tip
     >
     > If you don't receive the email with the reset password link, check your spam folder. If the email isn't there, choose *Return to Sign In* and start the process again. If the problem persists, contact your administrator for further assistance.

   - **Optional:** *Security Questions* - Provide the required information and answers, and press *Continue*.

     > → Remember
     >
     > To use this option, you must have configured the security questions section in your profile page. Note that the answers to the security questions are case sensitive. You must provide exactly the same answers that you have configured.

   - **Optional:** *PIN Code* - Provide the required information and PIN code, and press *Continue*.

     > → Remember
     >
     > To use this option, you must have configured the PIN code section in your profile page.

1.8.7 Error Messages on End User Screens

This section aims to help end users to deal with error messages when using applications for logon, registration, invitation, password update, and account activation.

Error Codes

Solutions to Error Messages

Error Message	Description	Solution
Authentication failed; try again	• You have entered the wrong credentials; • Your account is not activated.	• Try again; • Open your email and activate your account; • Register on the logon page; • Contact your administrator.
An error occurred; try again	An unexpected error occurred.	• Try again; • Contact your administrator.
Insufficient password complexity; check password requirements	Your password does not comply with the application's password policy.	Familiarize yourself with the password policy for the application.
Cannot verify your password; try again	The old password for the password update is invalid.	Enter your correct current password.
The password has already been changed in the last 24 hours	According to the application's policy, you are not allowed to change the password right now.	• Familiarize yourself with the application's policy for changing the password; • Try again later.
Your email activation link is invalid.	The email activation link that you have received is expired or already used by you.	• *Visit the application > choose Log On > follow Forgot Password link* • Contact your administrator.

Related Information

Getting Support [page 3141]

1.9 Development

The developer guide is aimed mainly at organization developers who can implement configurations in addition to the ones in the administration console of Identity Authentication. Developers can use REST API services

to configure various authentication and registration mechanisms for their applications. The applications that administrators configure use different application services for all user-related processes.

Application Services

The application services are used by the cloud services and cloud applications to interact with Identity Authentication with regard to user records in the tenant.

The following APIs are offered to cloud applications:

- An API to register users
  For more information, see User Registration [page 2807]
- An API to invite users
  For more information, see Invitation REST API [page 2802]
- Identity Authentication implementation of the System for Cross-domain Identity Management (SCIM) REST API protocol.
  For more information, see Identity Authentication API (Deprecated) [page 2796].
- An API to change the predefined texts and messages for end-user screens available per tenant in the Identity Authentication.
  For more information, see Change Tenant Texts REST API [page 2826].
- An API to change the predefined master data texts.
  For more information, see Change Master Data Texts REST API [page 2860].

Related Information

Error and Success Codes [page 2883]
Configure Certificates for API Authentication [page 2001]

1.9.1 API Authentication

Developers can choose the type of authentication when API methods of Identity Authentication are used.

The certificate to be used for authentication by the REST APIs of Identity Authentication must be requested from the SAP Support Portal.

Configure Secrets for API Authentication [page 2781]
This document describes how developers configure secrets with scopes and validity for client authentication.

Unlock Client ID [page 2783]
Unlock the client ID after five failed logon attempts before the automatic unlock time of 60 minutes has passed.

Disable Client ID Locking [page 2784]
You can disable the automatic lock of the client ID after five failed logon attempts.

Configure Certificates for API Authentication [page 2785]
: This document describes how developers configure the certificates used for authentication when the API methods and OpenID Connect scenarios of Identity Authentication are used.

Configure JWT for OAuth Client Authentication [page 2787]
: Configure the JSON Web Token (JWT) - the issuer and subject of tokens for JWT client authentication in token requests, or the URI for JSON web key retrieval for client authentication.

1.9.1.1 Configure Secrets for API Authentication

This document describes how developers configure secrets with scopes and validity for client authentication.

Context

You can use a client ID and a secret to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Password REST API) to the tenant of Identity Authentication are used. The client ID and secret can also be used in the OpenID Connect scenarios of Identity Authentication.

The client ID is in the universally unique identifier (UUID) format. For example, `1ab7c243-5de5-4530-8d14-1234a26373ab`.

> → Remember
>
> The User ID and a password (secret) to authenticate the client (relying party) in the OpenID Connect scenario must be encoded using the "application/x-www-form-urlencoded" encoding algorithm.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   > ⓘ Note
   >
   > Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
   >
   > If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.

   You can see the *Client ID* generated for the chosen application.

6. Choose the *Add* button in the *Secrets* section.

> **Restriction**
>
> You can generate up to 20 client secrets per application.

7. Provide the required info in the pop up.

Description	This field is optional.
Expire in	You can choose from three options: • 1 year • 2 years • Never
Scope	• Application - Secrets with *Application* scope are used to update the Application configurations. • Application Users - select this option to generate a secret to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Service REST API) are used. • OpenID - select this option to generate a secret to authenticate in the OpenID Connect scenario. **Note** By default all options are selected. Your secret can be used for all scopes.

8. Save your configuration.

   A pop up with the generated credentials appears. Make sure that you save the client secret for the client ID. You will need it for the API authentication, but you will not be able to retrieve it from the system later.

Results

Once your secret is generated you can see a table with your secrets and information about them.

1.9.1.2 Unlock Client ID

Unlock the client ID after five failed logon attempts before the automatic unlock time of 60 minutes has passed.

Context

The client ID locks for 60 minutes after five failed logon attempts. After 60 minutes the client ID is automatically unlocked.

To unlock the client ID before the automatic unlock time of 60 minutes has passed follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application with a locked client ID.
4. Under *API AUTHENTICATION*, choose *Client ID and Secrets*.
5. Choose *Unlock* next to *Client ID Status*.

> → Remember
>
> You can only unlock locked client IDs. If the client ID is not locked, the *Unlock* button is disabled.

Task overview: API Authentication [page 2780]

Related Information

Disable Client ID Locking [page 2000]

1.9.1.3 Disable Client ID Locking

You can disable the automatic lock of the client ID after five failed logon attempts.

Context

By default the client ID locks for 60 minutes after five failed logon attempts.

You can disable the automatic lock of the client ID via the administration console for SAP Cloud Identity Services. Use this option to disable the automatic lock in cases when the client ID has a limited scope and the client ID secret(s) are automatically generated.

> ### Note
>
> When you disable the *Client ID Lock* option for a client ID that is already locked, this resets the failed logon attempts counter but the client ID remains locked. If you want to unlock the client ID before the automatic unlock time of 60 minutes has passed you must unlock it manually. For more information, see Unlock Client ID [page 1999].

"

To disable the *Client ID Lock* option, follow the procedure below:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.
4. Under *API AUTHENTICATION*, choose *Client ID and Secrets*.
5. Disable the *Client ID Lock*.

   If the operation is successful, you receive the following message: `Client ID locking updated.`. The slider next to *Client ID Lock* is switched to *OFF*.

   > ### Note
   >
   > If you want to enable client ID password locking for the application, drag the slider to *ON*.

1.9.1.4 Configure Certificates for API Authentication

This document describes how developers configure the certificates used for authentication when the API methods and OpenID Connect scenarios of Identity Authentication are used.

Prerequisites

SAP Support Portal Home (For trusted CA Scenario) - If you want to configure a certificate, using your own trusted CA report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`. Attach to the incident the root and intermediate certificates and provide the Identity Authentication tenant ID.

> **Note**
>
> `Tenant ID` is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the `tenant ID`. For more information about your tenants, see View Assigned Tenants and Admins.

Context

You can use a certificate to authenticate when REST API calls (Invitation REST API, User management REST API, Password Service Rest API, and Forgot Service REST API) to the tenant of Identity Authentication are used. The certificate can also be used in the OpenID Connect scenarios of Identity Authentication.

For the configuration, you have to provide the base64-encoded certificate as a file or plain text, or you can generate a certificate via the administration console. You can enter a maximum of 80 certificates.

By default all scope options are selected and the *Scope* field is disabled. Your certificates are used for all scopes.

Identity Authentication, by default, supports the following as trusted certificate authorities (CA): SAP Passport CA G2, SAP SSO CA G2, SAP Cloud Root CA, SAP Global Root CA, DigiCert TLS RSA SHA256 2020 CA1, DigiCert Global Root CA, SAP Cloud Platform Client CA, ConnectivityCA.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.

3. Choose the application that you want to edit.

> ### Note
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.
6. Choose the *Add* button in the *Certificates for API Authentication* section.
7. **Optional:** Provide description for the certificate.
8. Choose one of the following options:

Certificate Options	Notes
Generate Certificate	Fill in the fields under *Generate Certificate* and choose the *Generate* button. **Note** You must provide a Common Name (CN) and password to generate the certificate. Once the certificate is generated, it is saved as a *.p12* file. The system populates the *Insert as Text* field with it, and provides the certificate attributes in the Subject DN. The common name (CN) in the generated certificate is in the format `<common name>` (`<admin user ID>`), where common name is the CN provided by the administrator, and admin user ID is the administrator's user id. The maximum length of the combination of `<common name>` (`<admin user ID>`) is 64 characters. **→ Remember** You can generate up to 500 certificates per year. If you reach the limit, you can still upload your certificate, or insert it as a text.
Upload Certificate	You must use `.cer` or `.crt` files. **Note** Once the certificate is uploaded, the system populates the Insert as Text field with it
Insert Certificate	Insert the certificate in the text field.

> ⚠ Restriction
>
> You can't use one and the same certificate for application and system as administrator authentication.

9. Choose the *Add* button at the bottom of the page.

   Once the certificate has been configured, the system displays the message `Certificate for API authentication updated`.

> → Tip
>
> When the certificate expires, follow the procedure again and configure a new one.

Results

Once your certificate is added you can see a table with all your certificates and information about them.

User Management REST API [page 2805]

1.9.1.5 Configure JWT for OAuth Client Authentication

Configure the JSON Web Token (JWT) - the issuer and subject of tokens for JWT client authentication in token requests, or the URI for JSON web key retrieval for client authentication.

Prerequisites

You have an OpenID Connect application.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

> **Note**
>
> Filter the list items in the search field by typing the name, display name, application ID, organization ID, or client ID, or choose the application from the list on the left.
>
> If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].

4. Choose the *Trust* tab.
5. Under *Application APIs*, choose *Client Authentication*.
6. Under *JSON Web Tokens*, configure one of the following options and save your changes:

   You can enter a maximum of 20 of each type of trust.

   - (For RFC 7523-based JWT client tokens) Choose the *Add* button for *Configure Trust by Issuer* and provide the required info in the popup:

     Configure Trust by Issuer

Field	Notes
Description	(Optional) - Provide information about the token in the provided field.
Choose *Issuer Configuration* > *Manual Configuration* > radio-button. **Note** When you choose *Manual Configuration* radio-button the *Corporate Identity Provider* section is not configurable.	Under *Manual Configuration* configure: 1. *Issuer* (Required) - The issuer must be OpenID Connect compliant. 2. *JSON Web Key Set URI* (Required) - Choose *Check for Metadata* button. If the entered issuer is verified as OpenID Connect compliant, the JSON Web Key Set URI will be retrieved automatically. Otherwise, you need to explicitly specify the *JSON Web Key Set URI* in the field. 3. *Refresh Interval* (Optional) - Refreshes the URI automatically if it is older than the selected interval. Choose from: • 24 hours (default choice) • 12 hours
Choose *Issuer Configuration* > *Corporate Identity Provider* > radio-button. **Note** When you choose *Corporate Identity Provider* radio-button, the *Manual Configuration* section is not configurable.	*Name* - (Required) Choose from OpenID Connect compliant corporate identity providers.

Field	Notes
General	1. *Subject* (Required) - The sub (subject) that is expected in the token. → Tip If you want to use an OAuth 2.0 token from a corporate identity provider as client credentials for an OpenID Connect application in Identity Authentication, and your OAuth client in the corporate identity provider belongs to a pre-configured application, the subject in the token is the Object ID of that pre-configured application. 2. *Audience* (Optional) - The `audience` claim of the identity provider. 3. `API Permission Groups` (Optional) - The field is enabled only when the *Provided APIs* option is configured. For more information, see Provide APIs for Consumption by Other Applications [page 2891].

- (For OpenID Connect-based JWT client tokens) Choose the *Add* button for *Configure Trust by URI* and provide the required info in the popup:

Configure Trust by URI

Field	Notes
Description	(Optional) You can provide information about the URI here.
URI	(Required) The JSON Web Key Set (JWKS) URI of the trusted party.
Refresh Interval	(Optional) Refreshes the URI automatically if it is older than the selected interval. Choose from: • 24 hours (default choice) • 12 hours
API Access	ⓘ Note This section is read-only. The predefined choice is OpenID.
API Permission Groups	(Optional) `API Permission Groups` field is enabled only when the *Provided APIs* option is configured. For more information, see Provide APIs for Consumption by Other Applications [page 2891].

: Validation of time-based one-time password (TOTP).

Change Tenant Texts REST API [page 2826]

The Change Tenant Texts REST API of Identity Authentication can be used to change the predefined texts and messages for end-user screens available per tenant in the Identity Authentication.

Change Master Data Texts REST API [page 2860]
The Change Master Data Texts REST API can be used to change the predefined master data for each resource in Identity Authentication.

1.9.2.1 Application Configurations API

Manage application configurations.

> **Note**
>
> The API is available on the SAP Business Accelerator Hub: Application Configurations API.
>
> Note that the Application Configurations API may return a higher number of applications than those displayed in the administration console. Some applications are used for internal purposes and are not shown in the admin console.

Prerequisites

To call the methods of this SCIM REST API you must have a system as administrator (technical user) with an assigned *Manage Users* role.

For more information, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

1.9.2.2.1 Extensions

The Identity Directory SCIM REST API can be manually extended by adding user attribute from a custom schema. The steps include:

1. Create custom schema in the administration console for SAP Cloud Identity Services. See Manage Custom Schemas via Administration Console [page 2388].

Example

You have set up a scenario where Identity Authentication acts as a proxy. The default authenticating identity provider is the corporate IdP, and the *Identity Federation* option is configured for that corporate IdP.

Michael Adams is a user from the corporate identity provider. He is created on the proxy IdP with the custom schema `urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile` with two single-valued attributes, `birthday` and `hobby`, and the complex attribute `name` with its child attribute `firstName`.

Sample Code

```
{
  "id": "urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile",
  "schemas": [
    "urn:ietf:params:scim:schemas:core:2.0:Schema"
  ],
  "name": "Profile",
  "description": "Custom schema description",
  "attributes": [
    {
      "name": "hobby",
      "description": "Custom attribute description",
      "canonicalValues": [

      ],
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "type": "string",
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "birthday",
      "description": "Custom attribute description",
      "canonicalValues": [

      ],
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "type": "string",
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "name",
      "description": "Custom complex attribute description",
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "type": "complex",
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none",
      "subAttributes": [
        {
          "name": "firstName",
          "description": "Custom subAttribute description",
          "canonicalValues": [
```

```
            ],
            "multiValued": false,
            "required": false,
            "caseExact": false,
            "type": "string",
            "mutability": "readWrite",
            "returned": "default",
            "uniqueness": "none"
          }
        ]
      }
    ]
}
```

2. Assign a custom schema to the user via one of the following options:
   - Assign an attribute from the custom schema via the administration console:
     1. *Access the administration console for Cloud Identity services* > *Users & Authorizations* > *User Management*.
     2. Select a user and choose the *Extensions* tab.

        > **Note**
        >
        > The attributes assigned from the custom schemas are visible there.

     3. Press the *Assign* button at the top of the page and choose which custom schema or schemas to add.
     4. Add values for for the attributes in the custom schema.

        > **→ Remember**
        >
        > To save your configuration you must add at least one value.

     5. Save your configuration.

        > **→ Tip**
        >
        > To unassign the already assigned schema, choose *Unassign* > *select the schema or schemas you want to unassign* > *Unassign*.

   - Assign an attribute form custom schema to the user by calling the Identity Directory SCIM REST API. See Identity Directory Service.

     > **Example**
     >
     > You have updated Michael's `hobby` attribute, by calling the *PATCH* method of Identity Directory Service.
     >
     > **Sample Code**
     >
     > ```
     > content-type: application/scim+json
     > Body:
     > {
     >     "schemas": [
     >         "urn:ietf:params:scim:api:messages:2.0:PatchOp",
     >         "urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile"
     >     ],
     >     "Operations": [
     > ```

```
        {
            "op": "add",
            "path":
"urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile:hobby",
            "value": "Chess playing."
        }
    ]
}
```

3. Send the already assigned custom attribute by configuring it in the default attributes sent to the application. See Configuring Attributes Based on Flexible Expressions [page 1979] under the *Send Identity Directory Custom Schema Attributes* section.

> ### Example
>
> The default attributes for the application are configured in the administration console as follows:
>
> Default Attributes Configuration in Administration Console
>
> | Attribute | Value |
> | --- | --- |
> | name | ${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.name.firstName} |
> | hobby | ${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.hobby} |
> | birthday | ${urn:sap:cloud:scim:schemas:extension:custom:2.0:Profile.birthday} |

1.9.2.3 Identity Provisioning API

Manage identity lifecycle processes for cloud and on-premise systems.

> ### Note
>
> The API is available on the SAP Business Accelerator Hub: Identity Provisioning API.

Prerequisites

To call the methods of this SCIM REST API you must have a system as administrator (technical user) with the following roles assigned:

- *Access Proxy System API*
- *Access Real-Time Provisioning API*
- *Access Identity Provisioning Tenant Admin API*

For more information, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

1.9.2.5 Migrating Deprecated Identity Authentication API to Identity Directory API

Migrating from the Identity Authentication API to Identity Directory API.

Documentation

Documentation Links

Identity Authentication Service API (Deprecated)	Identity Directory Service API (Successor)
Identity Authentication API	Identity Directory API

Endpoints Mapping

User Management

HTTP Method	Identity Authentication Service API (Deprecated)	Identity Directory Service API (Successor)
GET	`/service/scim/Users/`	`/scim/Users/`
GET	`/service/scim/Users/<id*>`	`/scim/Users/<id**>`
POST	`/service/scim/Users`	`/scim/Users`
PUT	`/service/scim/Users/<id*>`	`/scim/Users/<id**>`
DELETE	`/service/scim/Users/<id*>`	`/scim/Users/<id**>`

> **Note**
>
> *The <id*> is legacy `User ID`. It is a number starting with a letter. For example, `P123456`.

The <id> is in the universally unique identifier (UUID) format. For example, `1234fa2b-16or-4no7-87t7-26a02bf0bk69`.

Group Management Endpoints

HTTP Method	Identity Authentication Service API (Deprecated)	Identity Directory Service API (Successor)
GET	`/service/scim/Groups/`	`/scim/Groups/`
GET	`/service/scim/Groups/<id of the group*>`	`/scim/Groups/<id of the group**>`
POST	`/service/scim/Groups`	`/scim/Groups`
PUT	`/service/scim/Groups/<id of the group*>`	`/scim/Groups/<id of the group**>`
DELETE	`/service/scim/Groups/<id of the group*>`	`/scim/Groups/<id of the group**>`

ⓘ Note

The <id of the group> is in a legacy ID format. For example, `63c468ode3c07406970900kc`.

The <id of the group> is in the universally unique identifier (UUID) format. For example, `7369fa2b-16as-4sd7-87c7-26a01of0bk78`.

→ Remember

To assign group to a user, use the groups endpoint.

Attributes Mapping

Manage Users Attributes Mapping

Identity Authentication Service API (Deprecated)	Identity Directory Service API (Successor)
`id`	`urn:ietf:params:scim:schemas:extension:sap:2.0:User.userId`
`emails.value`	`emails.value`
`name.honorificPrefix`	`name.honorificPrefix`
`name.givenName`	`name.givenName`
`name.familyName`	`name.familyName`
`name.middleName`	`name.middleName`

1.9.2.6 Invitation REST API

The invitation service allows you to implement a request for user invitations. The invitees then receive an email containing information about how to register.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Resources

To configure the invitation service, you use a `POST` request with the following URI: `https://<Cloud Identity Services domain>/cps/invite/`.

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

Representation

You have to use a JSON representation of the invitation request by specifying *application/json* content type. All declared parameters in the request must also be JSON encoded.

Parameters

Required Parameters for the POST Method

Required Parameter	Description
`inviteeEmail`	The email of the invitee **Note** Only `inviteeEmail` or `inviteeUserId` should be used, not both.
`inviteeUserId`	The user ID of the invitee **Note** Only `inviteeEmail` or `inviteeUserId` should be used, not both.
`inviterName`	The display name of the user who sends the invitation.

Required Parameter	Description
`targetUrl`	The URL that the user is redirected to after registration. **→ Recommendation** From a usability perspective we recommend you to use URL of a protected page. **Note** The `targetUrl` parameter is optional if a *Home URL* is set for the application, and the application does not use overlay. If `targetUrl` is not specified, or the application uses overlay, the user is redirected to the application's *Home URL*, which must be set. For more information how to configure *Home URL*, see Configure an Application's Home URL [page 1937].
`sourceUrl`	The URL for the invitation link in the email sent to the invitee. The URL must be a public page. **Note** The `sourceUrl` parameter is optional if a `Home URL` is set for the application, and the application does not use overlay. If `sourceUrl` is not specified, or the application uses overlay, the user is redirected to the application's *Home URL*, which must be set. For more information how to configure *Home URL*, see Configure an Application's Home URL [page 1937].

Optional Parameters for the POST Method

Optional Parameter	Description
`inviteeFirstName`	The first name of the invitee
`inviteeLastName`	The last name of the invitee
`footerText`	The footer text of the invitation email
`headerText`	The header text of the invitation email
`language`	The preferred language for the invitation email. The usage of this parameter does not affect the end-user screens. Must be a string value specified by a two or four-letter code in one of the following formats: XX, xx, xx-XX or xx_XX. Otherwise the invitation email is in English.

Example

```
POST /cps/invite/
Content-Type: application/json
 {
  "inviteeEmail": "john.miller@company.com",
  "inviteeFirstName": "John",
  "inviteeLastName": "Miller",
  "inviterName": "Donna Moore",
  "footerText": "Invitation footer sample text",
  "headerText": "Invitation header sample text",
  "targetUrl": "http://www.myserviceprovider.com/protected_home_page/",
  "sourceUrl": "http://www.myserviceprovider.com/public_home_page/"
 }
```

1.9.2.7 User Management REST API

This REST API allows you to implement a request for user management, such as user registration, as well as SP user retrieval, deactivation and deletion.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Methods

HTTP Method	Action	URI
POST	User Registration [page 2807]	`https://<tenant ID>.accounts.ondemand.com/service/users`
GET	SP User ID Retrieval [page 2811]	`https://<tenant ID>.accounts.ondemand.com/service/users`
GET	SP User Information [page 2813]	`https://<tenant ID>.accounts.ondemand.com/service/users/<SP user ID>`
PUT	SP User Deactivation [page 2815]	`https://<tenant ID>.accounts.ondemand.com/service/users/<SP user ID>`
DELETE	SP User Deletion [page 2817]	`https://<tenant ID>.accounts.ondemand.com/service/users/<SP user ID>`

1.9.2.7.1 User Registration

The user registration is used for registration of new users or for on-behalf registration of partners.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Request

URI: `https://<Cloud Identity Services domain>/service/users`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`email`	Yes	String	The email of the user you register. The email must be unique. → Tip If email is mandatory, for users without valid email addresses or for testing purposes use the `sap-test.de` domain, for example `<username>@sap-test.de`. Do not use any other existing or nonexisting domains.	Request body
`user_profile_id`	No	String	The user ID	Request body
`login_name`	No	String	The logon name of the user	Request body
`applicationId`	No	String	The ID of the subscribed application. The user is created for the application with the provided ID.	Request body
`first_name`	No	String	The first name of the user you register. The allowed maximum length for the first name is 32 characters.	Request body
`last_name`	Yes	String	The last name of the user you register. The allowed maximum length for the last name is 64 characters.	Request body
`language`	No	String	The preferred language for the activation email of the user you register. The usage of this parameter does not affect the end-user screens. Must be a string value specified by a two or four-letter code in one of the following formats: XX, xx, xx-XX or xx_XX. Otherwise the activation email is in English.	Request body
`valid_from`	No	String	The *valid from* date	Request body
`valid_to`	No	String	The *valid until* date	Request body
`name_id`	No	String	The name ID of the user you register.	Request body

Parameter	Required	Data Type	Description	Parameter Type
`source_url`	No	String	The URL to the public page of the application where the Identity Authentication overlays are integrated. If not provided, the activation screen is shown without overlays. This parameter value must be URL-encoded. **⚠ Caution** Put `/` at the end of the source URL.	Request body
`target_url`	No	String	The URL to the application page that the user should be redirected to after he or she has completed account activation. If `target_url` is not provided, the user is redirected to the home URL configured for the service provider. For more information how to configure *Home URL*, see Configure an Application's Home URL [page 1937].	Request body
`send_email`	No	Boolean	Values: true (default value), false • If **true** - activation email is sent to the user. • If **false** - activation email is not sent to the user. **ⓘ Note** If the user is new, the link for account activation is returned with the **201** response.	Request body
`spCustomAttribute1`	No	String	Custom attributes are used to store additional information for the SP users. It is allowed to pass five customer attributes for a user	Request body
`spCustomAttribute2`	No	String	Custom attributes are used to store additional information for the SP users. It is allowed to pass five customer attributes for a user	Request body

Parameter	Required	Data Type	Description	Parameter Type
`spCustomAttribute3`	No	String	Custom attributes are used to store additional information for the SP users. It is allowed to pass five customer attributes for a user	Request body
`spCustomAttribute4`	No	String	Custom attributes are used to store additional information for the SP users. It is allowed to pass five customer attributes for a user	Request body
spCustomAttribute5	No	String	Custom attributes are used to store additional information for the SP users. It is allowed to pass five customer attributes for a user	Request body

Request Example

Example

> ⚠ Caution
>
> All parameters for the POST method must be written on one line.

```
POST /service/users
Content-Type: application/x-www-form-urlencoded
name_id=johns&user_profile_id=p987654&email=john.smith@sap.com&first_name=John&last_name=Smith&language=en&valid_from=20110901120000Z&valid_to=20120901110000Z&source_url=http%3A%2F%2Fwww.myapp.com%2Fpublic.jsp&target_url=http%3A%2F%2Fwww.myapp.com%2Fprotected.jsp&spCustomAttribute1=Industry
```

Response

Response Status and Error Codes

Code	Reason	Description
201	Created	The user is successfully created.
400	Bad Request	The user for whom you are trying to create an SP user is `inactive`.
409	Conflict	The SP user already exists.

For more information about the general error codes that may be returned, see Error and Success Codes [page 2883].

Response Example

Example

The URI of the created user is returned in the location header of the HTTP Response.

```
Location: https://<tenant ID>.accounts.ondemand.com/service/users/0800200c9a66
```

Example

In case of conflict, the URI of the conflicting user is returned in the location header of the HTTP Response.

```
Location: https://<tenant ID>.accounts.ondemand.com/service/users/467345637aa
```

Example

In case of creating a new user with "send_email=false", the activation link is returned in the HTTP Response body.

```
Content-Type: application/json
    {
         "activationLink" : "https://<tenant ID>.accounts.ondemand.com/ids/
activation?
token=I1830C497BF9B857B7D6298E5F117AF397I1F59A28838A3276E8B68FFFF54414C8843ACF395
A05401ABE6568FF3659D6EE96"
    }
```

Related Information

1.9.2.7.2 SP User ID Retrieval

To retrieve an SP (service provider) user's ID, you use the `GET` method.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Request

URI: `https://<Cloud Identity Services domain>/service/users`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/vnd.sap-id-service.sp-user-id+xml

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`name_id`	Yes	String	The name ID of the user you register. The `name_id` can be retrieved via the SP User Information [page 2813] API. It can be a User ID, Login name, etc.	Query string
`applicationId`	No	String	The ID of the subscribed application. The user is retrieved for the application with the provided ID.	Query string

Request Example

```
GET /service/users?name_id=johns
```

Response

Response Headers

Header	Description
`Location`	The ID of the created SP user is in the location header of the HTTP Response.

Response Example

```
Location: https://<tenant ID>.accounts.ondemand.com/service/users/<SP user ID>
```

Related Information

User Management REST API [page 2805]

1.9.2.7.3 SP User Information

To retrieve information for an SP (service provider) user, you use a `GET` method.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Request

URI: `https:/<Cloud Identity Services domain>.`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/vnd.sap-id-service.sp-user-id+xml

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`<SP user ID>`	Yes	String	The SP user id.	Path
`applicationId`	No	String	The ID of the subscribed application. The information for the SP useruser is retrieved for the application with the provided ID.	Query string

Request Example

```
GET /service/users/<the ID of the SP user>
```

Response

Response Attributes

The response returns the following attributes. Only the attributes that exist for the user are returned.

- user_profile_id
- name_id
- status
- profile_status
- valid_from
- valid_to
- activation_time
- email
- language
- first_name
- last_name
- sp_name
- login_name

- country
- city
- company_city
- spCustomAttributeX

Response Status and Error Codes

Code	Reason	Description
200	OK	The information for the user is returned in the response.
404	Not Found	The SP user with the provided ID does not exist.

Related Information

User Management REST API [page 2805]

1.9.2.7.4 SP User Deactivation

To deactivate an SP (service provider) user, you use a `PUT` method.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

Request

URI: `https://<Cloud Identity Services domain>/service/users/<SP user ID>`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *PUT*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/vnd.sap-id-service.sp-user-id+xml

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`status`	Yes	String	When the user activates his or her email, the `status` is set to **active**. To deactivate the SP user, update the `status` parameter by setting it to **inactive**. To activate the SP user, set it to **active**.	Request body
`applicationId`	No	String	The ID of the subscribed application. The user is deactivated for the application with the provided ID.	Query string

Request Example

```
PUT /service/users/<the ID of the SP user>
Content-type: application/vnd.sap-id-service.sp-user-id+xml; version=1.0
<user>
  <status>inactive</status>
</user>
```

Response

Response Status and Error Codes

Code	Reason	Description
200	Deactivated	SP user is successfully deactivated

For more information about the general error codes that may be returned, see Error and Success Codes [page 2883].

> **Note**
>
> If a user logs into an application he or she is deactivated for, the identity provider will block the logon and notify the application.

Response Example

```
<Response Consent="urn:oasis:names:tc:SAML:2.0:consent:unspecified"
          Destination="https://example.com/saml2/acs"
          Version="2.0"
          xmlns:ns2="urn:oasis:names:tc:SAML:2.0:assertion"
          xmlns="urn:oasis:names:tc:SAML:2.0:protocol"
          xmlns:ns4="http://www.w3.org/2001/04/xmlenc#"
          xmlns:ns3="http://www.w3.org/2000/09/xmldsig#"
          >
  <ns2:Issuer>accounts.sap.com</ns2:Issuer>
  <Status>
    <StatusCode Value="urn:oasis:names:tc:SAML:2.0:status:Responder">
      <StatusCode Value="urn:oasis:names:tc:SAML:2.0:status:AuthnFailed" />
    </StatusCode>
    <StatusMessage>The SP user [URI of the sp user] is with status inactive for
Service Provider [example.com]</StatusMessage>
  </Status>
</Response>
```

User Management REST API [page 2805]

1.9.2.7.5 SP User Deletion

Delete an SP (service provider) user.

Prerequisites

You need to set up the authentication type to access this API. You can use a *client ID* and a *secret*, or a certificate. For more information, see Configure Secrets for API Authentication [page 1997] or Configure Certificates for API Authentication [page 2001].

> ⚠ Caution
>
> If the last SP user is deleted, and the user is of type `type public`, then the whole user profile is deleted.

Request

URI: `https://<Cloud Identity Services domain>/service/users/<SP user ID>`

> ⓘ Note
>
> The domain part has the following pattern:

`<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *DELETE*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/vnd.sap-id-service.sp-user-id+xml

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`applicationId`	No	String	The ID of the subscribed application. The user is deleted for the application with the provided ID.	Query string

Request Example

```
DELETE /service/users/0800200c9a66
```

Response

Response Status and Error Codes

Code	Reason	Description
200	The operation is successful.	The SP user is deleted.

For more information about the general error codes that may be returned, see Error and Success Codes [page 2883].

Related Information

User Management REST API [page 2805]

1.9.2.8 Password Service REST API

The password service is used for operations related to user passwords, such as verification of the user name and the password combination.

Verify Username and Password Combination

Verify the username and password combination, or verify the thing ID and password combination.

Request

URI: `https://<Cloud Identity Services domain>/service/users/password`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` - Username and password are provided by the user. **Note** Depending on the allowed logon identifiers for the user, the username can be the `User ID`, `Login Name`, or `Email`. For more information, see Configure Allowed Logon Identifiers [page 2146]. **Caution** If the user provides wrong password, then each verification counts as a failed logon attempt. The password locks when the number of the allowed failed logon attempts is reached. The number depends on the password policy applied for the application. For more information, see Configuring Password Policies [page 2223].

Header	Required	Values
`Content-Type`	Yes	application/json

Request Example

```
POST /service/users/password
Authorization: Basic <Username/Password>
```

Response

Response Status and Error Codes

Code	Result or X-Message Code	Description
200 OK	Success	When the username and password combination or thing ID and password combination is verified.
401 Unauthorized	PASSWORD_LOCKED	When the password is locked for 60 minutes.
	PASSWORD_DISABLED	When the password is disabled.
	USER_INACTIVE	When the user is not in status active.
	PASSWORD_RESET_REQUIRED	When the user must reset his or her password before logon.
	PASSWORD_CHANGE_REQUIRED	When the user must change his or her password before logon.
	INITIAL_PASSWORD_EXPIRED	When the initial password of the user has expired. After the validity of the initial password expires, the user can't log on to the application and must contact the administrator.
	INVALID_AUTHORIZATION_HEADER_LENGTH	The time-based one-time password (TOTP) code is not provided, but Two-Factor Authentication (TFA) with TOTP is enabled.
	INVALID_OTP_CODE	Wrong TOTP code was provided.
	RBA_RULE_ACTION_DENY	Denied because of a risk-based authentication rule

Response Example

On success, the HTTP Response Body contains:

```
{
      "uid": "P000000",
      "first_name": "Dona",
      "last_name": "Moore",
      "mail": "dona.moore@example.com"
      "type": "employee"
   }
```

1.9.2.9 Forgot Password REST API

The forgot password REST API sends a reset password email.

The language of the reset password email is defined in the following order of importance:

Custom Template Sets Configured for Application

1. If the user is set with a specific language:
    1. if the language exists in the custom template, the system sends the reset password email in that language
    2. if the language does not exist in the custom template, the system sends the reset password email in English, if English exists in the custom template set
    3. if the language of the user, and the English language do not exist in the custom template, the system sends the reset password email in English from the *Default* template set
2. If the user is not set with a specific language:
    1. if English exists in the custom template set, the system sends the reset password email in English from the custom template set
    2. if English does not exist in the custom template set, the system sends the reset password email in English from the *Default* template set

Default Template Set Configured for Application

If the user is set with a specific language, the system sends the reset password email in that language, if it exists in the *Default* set. Otherwise, it sends the reset password email in English from the *Default* template set.

For more information about the email template sets, see Configuring Email Templates [page 2282].

→ Tip

Configure SAML 2.0 Service Provider [page 1941].

Request

URI: `https://<Cloud Identity Services domain>/service/users/forgotPassword`

ⓘ Note

The domain part has the following pattern:

`<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Authorization`	Yes	`Basic` • via application ((service provider (SP)) Authentication certificate • via SP REST API username and password For more information, see API Authentication [page 1996].
`Content-Type`	Yes	application/json

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`identifier`	Yes	string	supported attributes: • email → Tip If email is mandatory, for users without valid email addresses or for testing purposes use the `sap-test.de` domain, for example `<username>@sap-test.de`. Do not use any other existing or nonexisting domains. • loginName • uid	Request body

Request Example

```
{
    "identifier": "dona.moore@example.com"
}
```

Response

Response Status and Error Codes

Code	Reason	Description
200 OK	The user exists and password reset is allowed for the user profile.	Forgot password email is sent to the provided user. ⓘ Note Forgot password email is not sent when the response is **200 OK** in following cases: • the user does not exist • the limit of three forgot password e-mails sent for the last 24 hours has been reached
400 Bad Request	PASSWORD_TOO_NEW	When the password has already been changed for the last 24 hours..
	USER_INACTIVE	When the user status is `inactive`.

Code	Reason	Description
	PASSWORD_DISABLED	When the password is disabled.

1.9.2.10 TOTP Validation Service

Validation of time-based one-time password (TOTP).

The API is called on behalf of an application ((service provider (SP)).

Request

URI: `https://<Cloud Identity Services domain>/service/users/otp`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Authentication mechanisms:

- Client certificate
- Basic authentication

> **Note**
>
> For more information about the authentication mechanisms, see API Authentication [page 1996].

Request Headers

Header	Required	Values
`Content Type`	Yes	application/json

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`userName`	Yes	String	Provided by the user. The `userName` can be either the user email, the user login name, or the user profile ID.	Request body
`otpCode`	Yes	String	Provided by the user. The `otpCode` is the time-based one-time password (TOTP) to be validated.	Request body

Request Example

```
POST /service/users/otp
Content-Type: application/json
{
 "userName": "michael.adams@example.com",
 "otpCode": "123456"
}
```

Response

Response Status and Error Codes

Code	Result or X-Message Code	Description
200 OK	Success	The one-time password is valid.
401 Unauthorized	BAD_CREDENTIALS	The user isn't authenticated or the authentication failed due to wrong credentials.
	INVALID_OTP_CODE	The TOTP isn't valid.
	LOCKED_OTP_CODE	The user provided wrong TOTP five times. The user's passcode authentication is locked.

Code	Result or X-Message Code	Description
	USED_OTP_CODE	The TOTP is already used.

1.9.2.11 Change Tenant Texts REST API

The Change Tenant Texts REST API of Identity Authentication can be used to change the predefined texts and messages for end-user screens available per tenant in the Identity Authentication.

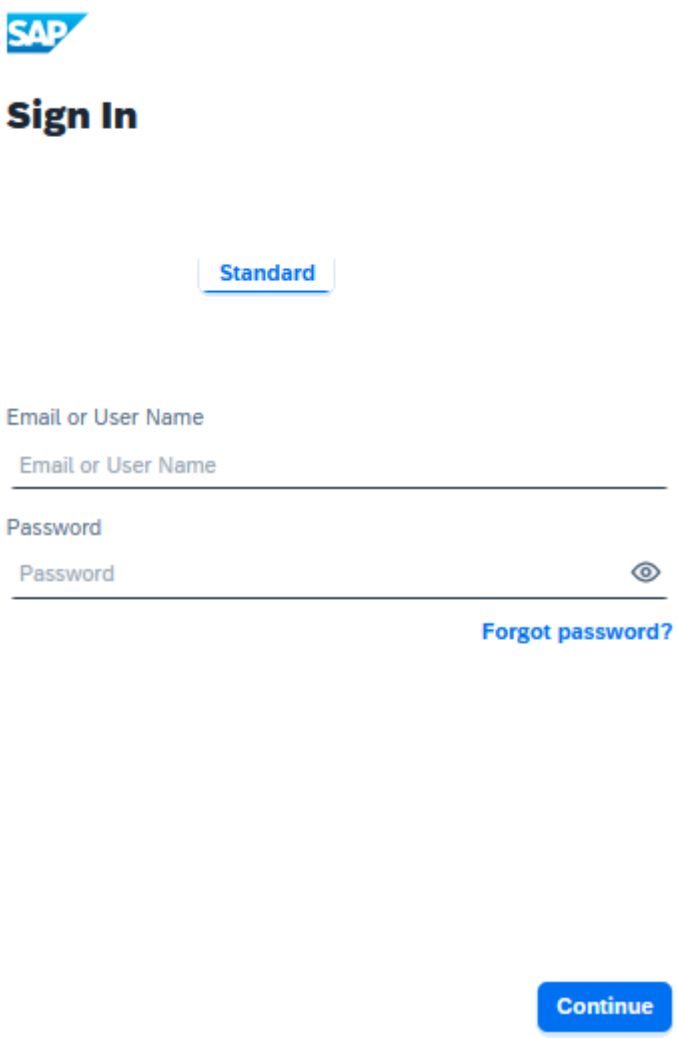
> **Note**
>
> We recommend you to change the tenant texts via the administration console of Identity Authentication. For more information, see Change Tenant Texts Via Administration Console [page 2121].

Prerequisites

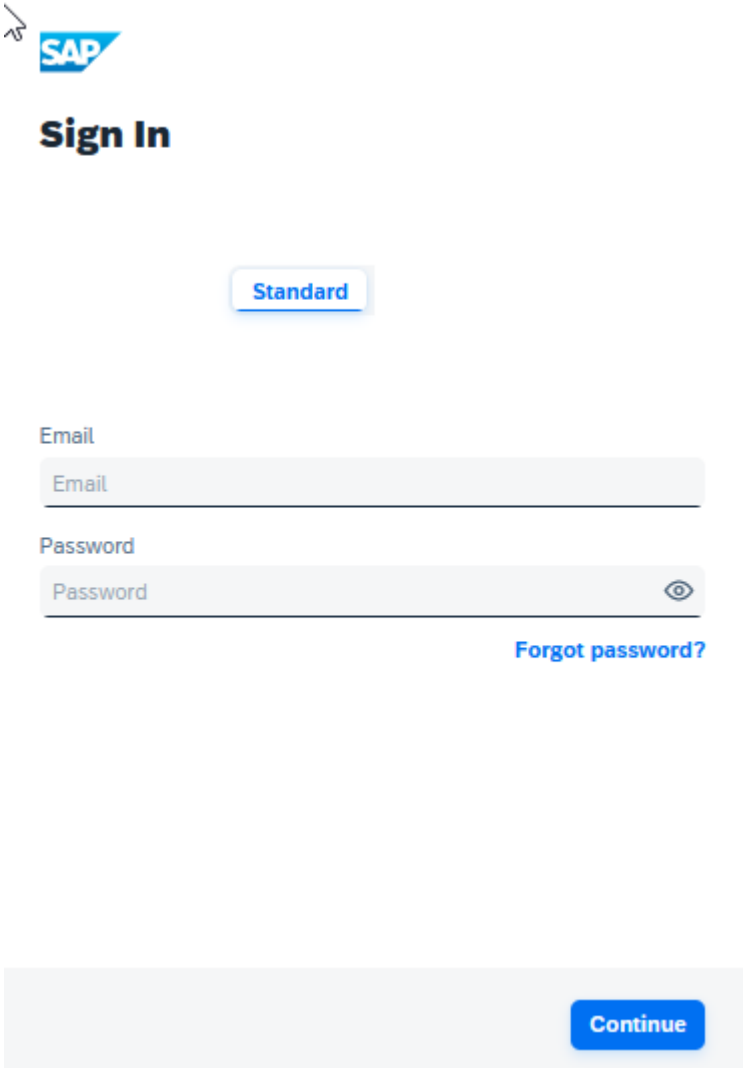
To call the methods of this Change Tenant Texts REST API you must have a system as administrator (technical user) with an assigned *Manage Tenant Configuration* role. For more information, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

Usage

The predefined tenant texts are stored in the Tenant Texts [page 2835] document. The document contains configurable parameters stored as key value pairs of strings. Each key stores the name of a parameter, and the corresponding value is the text that can be changed and updated. The keys are self-explanatory and show where the texts are used. For example, the `logon.ui.label.user=Email or User Name` key value pair is for the type of information that the user must provide to sign in to the application. On the *Sign In* screen you see:



If you want to change the user identifier text you have to update the key value pair `logon.ui.label.user=Email or User Name` to `logon.ui.label.user=Email` to receive:



> **Note**
>
> For some tenants some changed predefined changed texts may exist. If your tenant contains predefined changed texts, you can:
>
> - Use the **GET** method to obtain the texts that overwrote part of the predefined tenant texts when your custom tenant was created, change the texts that you want, add them to the **POST** request and upload them.
> - Use the **GET** method to obtain the texts that overwrote part of the predefined tenant texts when your custom tenant was created, delete a key value pair, add the texts without this line to the **POST** request and upload them. This will replace the deleted key value pair with the predefined one.
> - Open the Tenant Texts [page 2835] document, use the **GET** method to obtain the texts that overwrote part of the predefined tenant texts when your custom tenant was created, from the Tenant Texts [page 2835] document copy the key value pairs that were not included in the response, change the texts in the copied key value pairs, add these new key value pairs to the **POST** request, and execute it.
> - Open the Tenant Texts [page 2835] document, copy the texts to the **POST** request, and execute it. This will replace all texts in the tenant with the predefined ones.

→ Remember

If there are no predefined changed texts for your tenant, the GET Tenant Texts [page 2830] returns the *404 Not Found* code. In this case, proceed with the POST Tenant Texts [page 2833] method.

Methods

HTTP Method	See	URI
GET	GET Tenant Texts [page 2830]	`https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_I18N_BUNDLE&locale=<value>`
POST	POST Tenant Texts [page 2833]	`https://<tenant ID>.accounts.ondemand.com/service/resource/SAP_DEFAULT`

ⓘ Note

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with an URL in it. This URL contains the *tenant ID*.

1.9.2.11.1 GET Tenant Texts

For tenants that contain predefined changed texts, download the texts that overwrote part of the predefined tenant texts when your custom tenant was created.

Request

URI: `https://<Cloud Identity Services domain>/service/resource?resourceType=RESOURCE_I18N_BUNDLE&locale=<value>`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Content-Type: application/json

Permissions: You must have a system as administrator with an assigned *Manage Tenant Configuration* role. For more details about how to add a system as administrator and assign administrator roles, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

URL Parameters

Parameter	Required	Description	Notes
`setId`	No	The identifier of the scenario that the resource is related to.	The default value is `SAP_DEFAULT`
`resourceType`	Yes	The type of the resource.	Use `RESOURCE_I18N_BUNDLE`

Parameter	Required	Description	Notes
`locale`	Yes	The locale of the resource.	The end user screens of the applications that use Cloud Identity Services for authentication, support the following languages: Arabic (ar), Bulgarian (bg), Catalan (ca), Chinese PRC (zh_CN), Chinese Taiwan (zh_TW), Croatian (hr), Czech (cs), Danish (da), Dutch (nl), English United Kingdom (en_GB), English United States (en_US), Estonian (et), Finnish (fi), French Standard (fr), French Canada (fr_CA), German Standard (de), Greek (el), Hebrew (iw), Hungarian (hu), Italian (it), Japanese (ja), Korean (ko), Latvian (lv), Lithuanian (lt), Malay (s), Norwegian (no), Polish (pl), Portuguese Portugal (pt), Romanian (ro), Russian (ru), Serbian (sr), Slovak (sk), Slovenian (sl), Spanish Standard (es), Spanish Mexico (es_MX), Swedish (sv), Thai (th), Turkish (tr), Ukrainian (uk), Vietnamese (vi), Welsh (cy).

Request Example

```
GET /service/resource?resourceType=RESOURCE_I18N_BUNDLE&locale=en
```

Response

Response Status and Error Codes

Success Codes

Code	Meaning	Description
200 OK	The request was successful.	OK

Error Codes

Response Code	Meaning	Description
400	Bad Request	Validate JSON data. Validate that the special characters are escaped properly and new lines are added.

Response Code	Meaning	Description
401	Unauthorized	The client is not authenticated.
403	Forbidden	Access to the resource is denied.
404	Not Found	The requested resource cannot be found.
405	Method Not Allowed	The requested method is not supported for the given resource.
415	Unsupported Media Type	The REST service does not support the API version requested by the REST client.
500	Internal Server Error	The operation cannot be completed due to a service error.
503	Service Unavailable	The service is currently unavailable.

Response Example

```
registerSuccess.thankyou=Thank you for registering with {0}
registerForm.validation.accept.privacy.statement=To accept the privacy
statement, click the box above
registerSuccess.activateAccount=To activate your account, click the link
contained in the e-mail. Note that it might take a few minutes for the e-mail
to reach your inbox.
accountActivation.ui.label.activationsuccesstext=Thank you for registering and
activating your account
accountActivation.ui.label.activationtext=This account can also be used to
access other applications
createForgottenPasswordMail.user=E-Mail
logon.ui.label.user=E-Mail
profileManagement.socialSignOn.unlinkWarning=Choose "Unlink" to remove your
social logon information from your account. You can re-link your account the
next time you log on with a social sign-on-enabled site.
accountActivation.ui.label.notlinkedtext=Your account does not currently use
social sign-on. To link your account with a social sign-on account, click one
of the social network buttons next time you log on.
profileManagement.socialSignOn.nolinktext=Your account does not currently use
social sign-on. To link your account with a social sign-on provider, click one
of the social network buttons next time you log on.
linkSocialSignOnAccount.headline=Link your account with {0}
linkSocialSignOnAccount.message.profile=Profile Page
linkSocialSignOnAccount.message=As a final step, you can either link an existing
account to your {0} account, or create a new account that will be linked to your
{0} account.
logon.ui.tooltip.SOCIAL_NOT_ALLOWED=The site you are attempting to access
requires your password.  Enter your password and click Continue.
oauth.network=The selected social sign-on service is currently unavailable. Use
a different social sign-on or your credentials to log on.
logon.ui.tooltip.MISSING_GOOGLE_PLUS_PROFILE=This Google account has not joined
Google yet. Join Google and link your account, or log on with an existing
account.
general.auth.request.error=Identity Provider could not process the
authentication request received. Delete your browser cache and stored cookies,
and restart your browser. If you still experience issues after doing this,
please contact your administrator.
```

1.9.2.11.2 POST Tenant Texts

Update the tenant texts.

> ⚠ Caution
>
> Make sure that you have applied the proper escaping in your **POST** request.
>
> You should add *\n* at the end of each line in the data property content.
>
> Escape Sequences

Value	Escape Sequences
\b	Backspace (ascii code 08)
\f	Form feed (ascii code 0C)
\n	New line
\r	Carriage return
\t	Tab
\"	Double quote
\\	Backslash character

> → Tip
>
> Instead of editing the request manually, you can use an on-line tool for converting a normal string into a quoted one.

Request

URI: `https://<Cloud Identity Services domain>/service/resource/SAP_DEFAULT`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: POST

Content-Type: application/json

Permissions: You must have a system as administrator with an assigned *Manage Tenant Configuration* role. For more details about how to add a system as administrator and assign administrator roles, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

Request Example

```

1.9.2.11.4 Tenant Texts Allowed HTML Elements

Allowed Elements

Allowed Elements

Category	Description	Tags
Inline text & emphasis	Phrasing-level formatting.	`span`, `strong`, `em`, `b`, `i`, `u`, `s`, `mark`, `small`, `sub`, `sup`
Inline semantic	Phrasing with semantic meaning.	`abbr`, `cite`, `q`, `time`, `data`, `bdi`, `bdo`, `ins`, `del`
Code & technical phrasing	Inline and preformatted technical text.	`code`, `kbd`, `samp`, `var`, `pre`
Block-level text	Paragraphs and block quotations.	`p`, `blockquote`
Headings	Section headings, plus heading group.	`h1`, `h2`, `h3`, `h4`, `h5`, `h6`, `hgroup`
Sectioning & generic containers	Document outline and grouping.	`div`, `header`, `footer`, `main`, `article`, `section`, `aside`, `nav`, `address`
Lists	Ordered, unordered, description, and command lists.	`ul`, `ol`, `li`, `dl`, `dt`, `dd`, `menu`

Category	Description	Tags
Tables	Tabular data and column groups.	`table`, `thead`, `tbody`, `tfoot`, `tr`, `th`, `td`, `caption`, `colgroup`, , `col`
Figures	Figure containers. **Note** `img` is not permitted	`figure`, `figcaption`, `picture`
Line breaks & separators	Soft and hard breaks; thematic break.	`hr`, `br`, `wbr`
Ruby annotations	East Asian pronunciation guides.	`ruby`, `rt`, `rp`, `rb`, `rtc`
Interactive disclosure & gauges	Native disclosure widget and progress/meter indicators.	`details`, `summary`, `progress`, `meter`
Anchors	Hyperlinks (may appear with or without attributes).	`a`
Legacy representative	Deprecated HTML4 styling tag.	`font`

Element Specific Attributes

Element Specific Attributes

Element(s)	Attribute(s)	Constraint
`abbr`	`title`	No
`time`, `ins`, `del`	`datetime`	No
`blockquote`, `q`	`cite`	No
`data`	`value`	No
`bdo`, `bdi`	`dir`	`ltr` or `rtl` (case-insensitive)
`ol`	`start`, `type`, `reversed`	No
`li`	`value`	No
`th`, `td`	`colsoan`, `rowspan`, `scope`, `headers`	No
`th`	`abbr`, `scope`	No
`col`, `colgroup`	`span`	No
`table`	`summary`	No
`details`	`open`	No
`progress`	`value`, `max`	No
`meter`	`value`, `min`, `max`, `low`, `high`, `optimum`	No

Element(s)	Attribute(s)	Constraint
`font`	`size`, `color`, `face`	No
`a`	`href`	Permitted URL schemes only (see table below)
`a`	`target`	`_blank`, `_self`, `_parent`, `_top` (case-insensitive)
`a`	`rel`	Must start with a letter; letters, white-space, and hyphens only

Global Attributes (allowed on every element)

Global Attributes

Attribute	Notes
`id`	Element identifier.
`class`	CSS class names.
`data-safermailto-subject`	Custom data attribute used by the email-link protection feature.
`data-safermailto-recipient`	Custom data attribute used by the email-link protection feature.
`data-safermailto-domain`	Custom data attribute used by the email-link protection feature.

Permitted URL Schemes

Permitted URL Schemes

Scheme	Status
`http`	Permitted
`https`	Permitted
`mailto`	Permitted
`ftp`	Permitted
`javascript`	Rejected
`data`	Rejected

> **Note**
>
> The `style` attribute is not in the allow list. Visual styling must be applied via `class`.
>
> If you want to add style to an HTML element, you should use a custom CSS. For more information, see Use a Custom CSS [page 2040].

1.9.2.12 Change Master Data Texts REST API

The Change Master Data Texts REST API can be used to change the predefined master data for each resource in Identity Authentication.

Prerequisites

To call the methods of this Change Master Data Texts REST API you must have a system as administrator (technical user) with an assigned *Manage Tenant Configuration* role. For more information, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

Usage

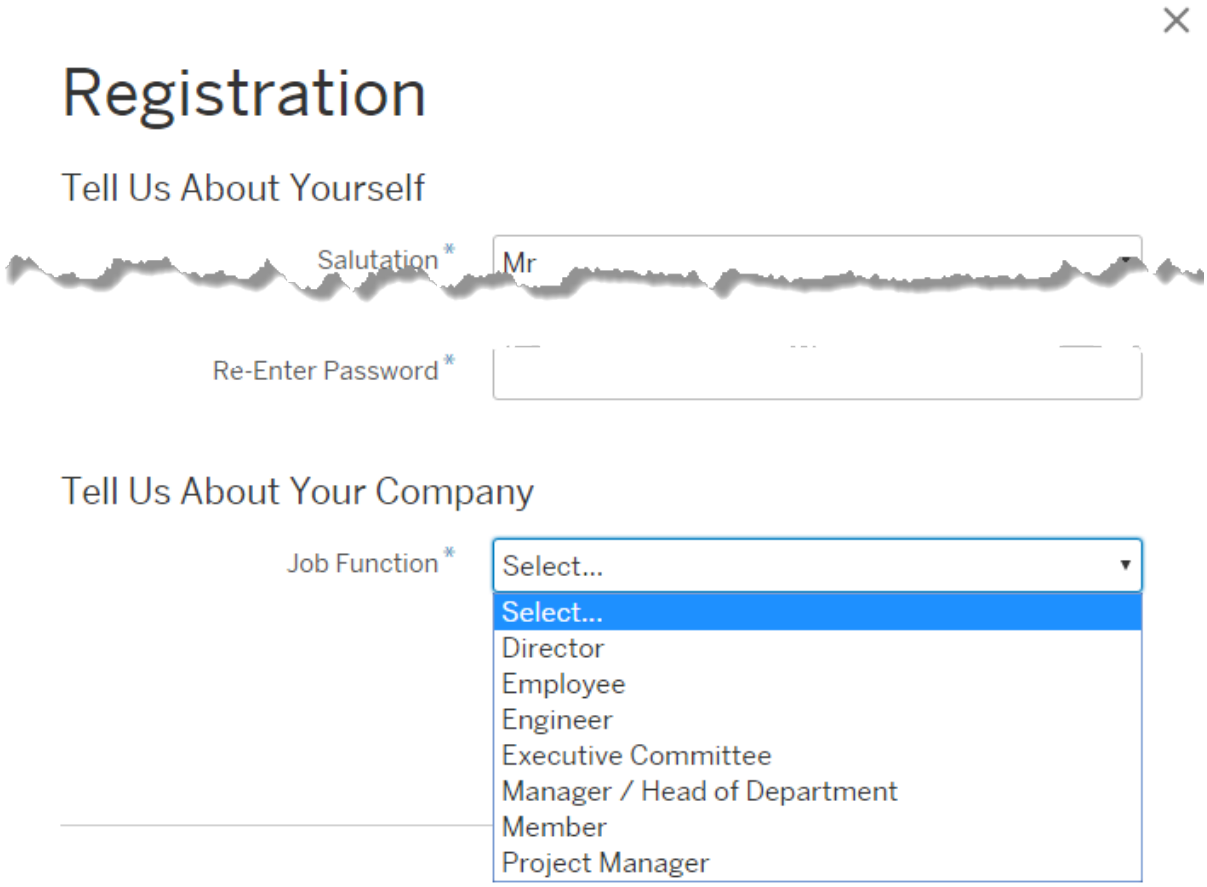
The predefined master data represents records in Identity Authentication that contain all relevant system data about a resource (Salutations, Functions, Departments, Company Relationships, Industries, Languages, Countries). That data can be used by the system for different classifications in the organization, for example, job titles, departments, or countries. The predefined master data texts are stored in `properties` documents which can be accessed from the links in the table below.

Predefined Master Data Texts

Resource	Link	Notes
Salutations	Salutations.properties [page 2868]	Key value pairs with a predefined set of honorifics.
Functions	Functions.properties [page 2868]	Key value pairs with a predefined set of job titles.
Departments	Departments.properties [page 2868]	Key value pairs with a predefined set of departments.
Company Relationships	Relationships.properties [page 2869]	Key value pairs with a predefined set of business entities, such as customer, partner, employee.
Industries	Industries.properties [page 2870]	Key value pairs with a predefined set of industries.
Languages	Languages.properties [page 2870]	Key value pairs with a predefined set of languages.
Countries	Countries.properties [page 2873]	Key value pairs with a predefined set of countries.

The files contain configurable parameters stored as key value pairs of strings. Each key stores the unified key of the resource, and the corresponding value is the unified value of the resource that can be changed and updated.

The example below shows the customized values of the *Functions* file. The dropdown list in the *Job Function* field on the *Registration* form shows the new values that have overwritten the predefined texts in the file.



Depending on your requirements, you can:

- Use the **GET** method to obtain the texts that you have already overwritten in the predefined master data texts, change the texts that you want, add them to the **POST** request and upload them.
- Use the **GET** method to obtain the texts that you have already overwritten in the predefined master data texts, delete a key value pair, add the texts without this line to the **POST** request and upload them. This will replace the deleted key value pair with the predefined one.
- Open the respective `properties` document from the link in the table, use the **GET** method to obtain the texts that overwrote part of the predefined master data texts when your custom tenant was created, from the downloaded file copy the key value pairs that were not included in the response, change the texts in the copied key value pairs, add these new key value pairs to the **POST** request, and execute it.
- Open the respective `properties` document from the link in the table, copy it to the **POST** request, and execute it. This will replace all texts with the predefined ones.

> ⚠ Caution
>
> Be careful if you change the keys when overwriting data texts, because this can result in invalid values. If a user has a certain value assigned, and the key value pair is overwritten with a different key, then the value for that property of the user will be no longer valid and visualized. For example, if you have set "Mr." to a user, and the key-value pair is "01=Mr.". If you overwrite the key value pair with "03=Mr.", "Mr." will not be visualized for that user.
>
> When overwriting data texts, the keys for the different languages must be one and the same. For example, the master data texts for the German locale are overwritten, and the tenant administrator wants to overwrite the texts for the French locale. The keys for the German locale should be obtained first and used as keys for the French locale. After that the values can be translated in French.

Methods

HTTP Method	See	URI
GET	GET Master Data Texts [page 2863]	`https://<tenant ID>.accounts.ondemand.com/service/resource?resourceType=RESOURCE_MD_<VALUE>&locale=<value>`
POST	POST Master Data Texts [page 2866]	`https://<tenant ID>.accounts.ondemand.com/service/resource/SAP_DEFAULT`

> ⓘ Note
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*.

1.9.2.12.1 GET Master Data Texts

Download the texts that you have already overwritten in the predefined master data texts.

> → Remember
>
> If you haven't overwritten the predefined master data texts the GET request will return the *404 Not Found Resource not found for scenario* response.

Request

URI: `https://<Cloud Identity Services domain>/service/resource?resourceType=<value>&locale=<value>`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *GET*

Permissions: You must have a system as administrator with an assigned *Manage Tenant Configuration* role. For more details about how to add a system as administrator and assign administrator roles, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

URL Parameters

Parameter	Required	Description	Notes
`setId`	No	The identifier of the scenario that the resource is related to.	The default value is `SAP_DEFAULT`

Parameter	Required	Description	Notes
`resourceType`	Yes	The type of the resource.	Use: • `RESOURCE_MD_SALUTATIONS` • `RESOURCE_MD_FUNCTIONS` • `RESOURCE_MD_DEPARTMENTS` • `RESOURCE_MD_RELATIONSHIPS` • `RESOURCE_MD_INDUSTRIES` • `RESOURCE_MD_LANGUAGES` • `RESOURCE_MD_COUNTRIES`
`locale`	Yes	The locale of the resource.	The default languages are: • Chinese (zh_CN) • Dutch (nl) • English (en) • French (fr) • German (de) • Hebrew (iw) • Italian (it) • Japanese (ja) • Korean (ko) • Polish (pl) • Portuguese (pt) • Russian (ru) • Spanish (es) • Welsh (cy) • Swedish (sv)

Request Example

```
GET /service/resource?resourceType=RESOURCE_MD_SALUTATIONS&locale=en
Content-Type: application/json
```

Response

Response Status and Error Codes

Success Codes

Code	Meaning	Description
200 OK	The request was successful.	OK

Error Codes

Response Code	Meaning	Description
400	Bad Request	Validate JSON data. Validate that the special characters are escaped properly and new lines are added.
401	Unauthorized	The client is not authenticated.
403	Forbidden	Access to the resource is denied.
404	Not Found	The requested resource cannot be found.
405	Method Not Allowed	The requested method is not supported for the given resource.
415	Unsupported Media Type	The REST service does not support the API version requested by the REST client.
500	Internal Server Error	The operation cannot be completed due to a server error.
503	Service Unavailable	The service is currently unavailable.

Response Example

Example of response that returns overwritten values of the *Salutations* file.

```
{
  0001=Dr.,
  0002=Prof.
}
```

Example of response that returns overwritten keys of the *Salutations* file. The keys can differ from the original in the master data file. It is not necessary to be in sequence.

```
{
  01=Ms.,
  05=Mr.
}
```

1.9.2.12.2 POST Master Data Texts

Update the master data texts.

> ⚠ Caution
>
> Make sure that you have applied the proper escaping in your **POST** request.
>
> You should add *\n* at the end of each line in the data property content.
>
> Escape Sequences

Value	Escape Sequences
\b	Backspace (ascii code 08)
\f	Form feed (ascii code 0C)
\n	New line
\r	Carriage return
\t	Tab
\"	Double quote
\\	Backslash character

> → Tip
>
> Instead of editing the request manually, you can use an on-line tool for converting a normal string into a quoted one.

Request

URI: `https://<Cloud Identity Services domain>/service/resource/SAP_DEFAULT`

> ⓘ Note
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: POST

Permissions: You must have a system as administrator with an assigned *Manage Tenant Configuration* role. For more details about how to add a system as administrator and assign administrator roles, see Add System as Administrator [page 2305], and Edit Administrator Authorizations [page 2309].

Request Example

```
https://<tenantId>.accounts.ondemand.com/service/resource/SAP_DEFAULT
Content-Type: application/json
Body:
[{
"resourceType": "RESOURCE_MD_DEPARTMENTS",
"locale": "en",
"contentType": "text/html;charset=UTF-8",
"data": "01=HR\n02=IT"
}]
```

Response

Response Status and Error Codes

Success Codes

Code	Meaning	Description
200 OK	The request was successful.	OK

Error Codes

Response Code	Meaning	Description
400	Bad Request	Validate JSON data. Validate that the special characters are escaped properly and new lines are added.
401	Unauthorized	The client is not authenticated.
403	Forbidden	Access to the resource is denied.
404	Not Found	The requested resource cannot be found.
405	Method Not Allowed	The requested method is not supported for the given resource.
415	Unsupported Media Type	The REST service does not support the API version requested by the REST client.
500	Internal Server Error	The operation cannot be completed due to a server error.
503	Service Unavailable	The service is currently unavailable.

1.9.3 Developing Authorizations

Developers define, update, and create authorizations. These are the basis for Authorization Management, which administrators can use to grant users access to resources.

Authorization Management enables SAP Cloud Identity Services administrators to use instance-based authorizations in the form of authorization policies in multiple environments. They assign authorization policies to users and thus manage user access to resources.

Developers define and deploy an application that supports authorization policies in SAP Cloud Identity Services. They include functional checks, instance-base authorizations, and user attributes. Authorization Management is automatically enabled for a new tenant and can be used as soon as an application requests it. Service instances and bindings are added automatically. The authorization policies are available in the SAP Cloud Identity Services administration console.

Developing Authorization Policies

Developers can use the Cloud Application Programming model for authorization policies. We've provided a sample application, which you can use for the creation of authorization policies.

- Authorization and Access Control with the Cloud Application Programming model
- Sample apps in GitHub

> **Note**
>
> Changes in the assignment of authorization policies usually take up to 15 seconds to propagate due to caching delays. The delay can also be longer. So, respect this waiting time.

Defining Authorization Policies

The Data Control Language (DCL) enables developers to define authorization policies and rules using an SQL-like syntax in SAP Cloud Identity Services. This declarative language allows them to specify access controls for data and resources through structured authorization policy definitions.

- Define authorization policies using SQL-like syntax.
- Create reusable authorization policies with attributes and conditions.
- Enable administrators to combine and refine rules into custom authorization policies.
- Support user assignment in the administration console.

DCL provides essential elements including rules, resources, conditions, attributes, schemas, and packages for enterprise-grade access control implementation. For more information, see SAP Cloud Identity Services Developer Guide .

1.9.4 Add Logon Overlays in Customer Applications

This document describes how service providers that delegate authentication to Identity Authentication can use embedded frames, also called overlays, for the logon pages of their applications.

Prerequisites

- You have a customer application. For more information, see Application Types [page 63].
- You have added the domains of the applications for which you want to use overlays as trusted in the administration console for SAP Cloud Identity Services. For more information, see Configure Trusted Domains [page 2173].

Context

The use of overlays maintains the application context, by keeping the application page as dimmed background, to provide for minimum disturbance to the workflow. By default, after a successful logon via an overlay page,

the application's parent page reloads. For more information how to configure that option, see Enable or Disable Reload Parent Page Option [page 2044].

> **Note**
>
> When the application uses overlay for the logon page, but the client's browser doesn't accept third party cookies, the logon page opens in fullscreen.
>
> To open the logon page of the application in an overlay instead of in fullscreen when the browser is set not to accept third-party cookies, the user has to add an exception for the domain of this application. The users can consult the documentations of the different browsers for more information about how to enable third-party cookies for specific Web sites and domains.

To add a logon overlay into your application proceed as follows:

Procedure

1. Include the following libraries to the landing page of your application:
   - *jQuery*
     If you have already included *jQuery* you don't need to do it again.
     You can download the *jQuery* from a Content Delivery Network (CDN), or you can use the following pattern:

     > **Sample Code**
     >
     > ```
     > <script src="https://<tenant ID>.accounts.ondemand.com/ui/resources/
     > javascripts/jquery.min.js"></script>
     > ```

   - SAP_IDS.js
     Use the following pattern:

     > **Sample Code**
     >
     > ```
     > <script src="https://<tenant ID>.accounts.ondemand.com/ui/resources/
     > javascripts/SAP_IDS.js"></script>
     > ```

   > **Caution**
   >
   > Make sure that the reference to the javascript file is pointing to the same Identity Authentication tenant that is used for authentication of this application. Have this in mind when you migrate your applications from quality to productive environment, if different Identity Authentication tenants are used.

2. Add a logon link.

> ### Note
>
> The logon link must be an HTML anchor with the following attributes:

Attribute	Value
rel	IDS_login
href	• points to an actual resource in your application that generates SAML 2.0 authentication request to Identity Authentication • the name of the resource isn't important

> ### Sample Code
>
> ```
> <a href="/login.jspa" rel="IDS_Login">Log in</a>
> ```

Results

When the user chooses the logon link, the following happens:

- If the user isn't logged on, the log on overlay is displayed.
- If the user is logged on to an application with the same Identity Authentication tenant, in other words he or she has an active application session, the user is automatically logged on to the second application.

> ### Caution
>
> The logon link should be visible only if the user doesn't have an active application session.
>
> If you still want to show the logon link when the user has an active application session, you must change the logic for the logonon link for this case. The logon link should not contain `rel="IDS_Login"` in this case. For example, the logic could be that, when the user chooses the logon link, he or she is directly redirected to the protected resource.

Next Steps

Protect applications against clickjacking when using overlays. For more information, see Configure Clickjacking Protection [page 2882].

Further Options

Locale

If the locale is known, this can be communicated to Identity Authentication by adding a locale parameter to *SAP_IDS.js*.

Sample Code

```
<script src="https://<tenant ID>.accounts.ondemand.com/ui/resources/
javascripts/SAP_IDS.js?locale=en_GB"></script>
```

Note

The locale parameter follows the Java specifications for a locale and must be of the format `ll_CC` where:

- `ll` is the language two letter code in small letters
- `CC` is the country (region) two letter code in capital letters

Token URL Separator

If your application is using overlays, you can configure the delimiter used in the token URL sent for the different application processes, such as forgot password, for example.

You can choose from:

- `;` - parameter, the default configuration
- # - fragment
- `?/&` - query string parameter

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the application that you want to edit.

   ### Note

   Type the name of the application in the search field to filter the list items, or choose the application from the list on the left.

   If you don't have a created application in your list, you can create one. For more information, see Create a New Application [page 1922].
4. Choose the *Branding and Layout* tab.
5. Under *Email Configurations*, choose the *Token Url Separator* list item.
6. Choose a deliminator from the list:
   - `;` - parameter, the default configuration

- # - fragment
- ?/& - query string parameter

7. Save your selection.

1.9.5 Rate Limiting and Throttling

This section provides information on the rate limiting and throttling in Identity Authentication.

Requests

To ensure a safe and stable environment, all requests have a limit of 50 concurrent requests per second. The requests are associated with the originating IP address, and not with the user making the requests.

When the limit is exceeded, the client receives the `HTTP 429 Too Many Requests` response status code.

> ⚠ Restriction
>
> Executing performance tests on Cloud Identity Services tenants requires approval from SAP. For more information, see KBA 3667040 - Performance and Stress tests for SAP Cloud Identity Services.

SCIM API

To prevent Identity Authentication from being overloaded by too many requests, we have introduced SCIM API throttling to regulate the API usage per tenant.

SCIM API Throttling

Requests per minute	Notes
up to 200	The requests are carried out.
201–280	The requests are delayed by 1 second.
281 and more	The client receives the `HTTP 429 Too Many Requests` response status code for 60 seconds.

OpenID Connect (OIDC) Endpoints

To ensure a safe and stable environment, all requests to the `/oauth2` endpoints have a limit of 1000 requests per minute per tenant. When the limit is exceeded, the client receives the `HTTP 429 Too Many Requests` response status code.

For a list of the relevant endpoints, use the following URL:

`https://<tenant ID>.accounts.ondemand.com/.well-known/openid-configuration`

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

If you've a custom domain configured, the URL has the following pattern:

`https://<your custom domain>/.well-known/openid-configuration`

SAML 2.0 Endpoints

To ensure a safe and stable environment, all requests to the `/saml2` endpoints have a limit of between 12000 and 15000 requests per minute per tenant. When the limit is exceeded, the client receives the `HTTP 429 Too Many Requests` response status code.

1.9.6 Configure Clickjacking Protection

Clickjacking is an attempt to trick users into clicking hidden user interface elements without the user realizing it. The user thinks he or she is clicking on the underlying frame, but is actually clicking on an action chosen by the attacker.

You have two options to protect your applications against clickjacking when using embedded frames, also called overlays, for the logon pages of the applications:

- If the applications are SAP UI5 or Web Dynpro, or they use the overlays of Identity Authentication, add the domains of these applications as trusted in the administration console for SAP Cloud Identity Services. For more information, see Configure Trusted Domains [page 2173].
- If the applications are not SAP UI5 or Web Dynpro, or they do not use the overlays of Identity Authentication, add the following code to your message handler:

Sample Code

```
function messageHandler(oEvent){
        if(oEvent.data=='SAPFrameProtection*require-origin'){
                oEvent.source.postMessage('SAPFrameProtection*parent-
origin','*');
        }
}
```

Related Information

Add Logon Overlays in Customer Applications [page 2877]

1.9.7 Error and Success Codes

This section is to help developers with solutions to the REST API response codes.

Error Codes

General Error Codes

Response Code	Meaning	Description
301	Permanent Location	The requested resource resides on a URI other than the requested one.You need to set up the authentication type to access the API.
400	Bad Request	The requested operation cannot be executed because the service cannot understand the data sent in the entity body of the request.
401	Unauthorized	The client is not authenticated.
403	Forbidden	Access to the resource is denied.
404	Not Found	The requested resource cannot be found.
405	Method Not Allowed	The requested method is not supported for the given resource.
406	Not Acceptable	You need to set up the authentication type to access the API.The requested method does not produce any of the media types requested in the HTTP request.
409	Conflict	The operation cannot be completed because it conflicts with an existing resource.
415	Unsupported Media Type	The REST service does not support the API version requested by the REST client.
500	Internal Server Error	The operation cannot be completed due to a service error.
503		The service is currently unavailable.

In addition to the general error codes, the REST APIs return one of the following detailed error codes as an *X-message-code* HTTP response header:

Detailed Error Codes

REST API	X-message code	Description
Invitation REST API	INVITATION_API_PARAMETER_INCORRECT	You have used an invalid parameter.
	INVITATION_API_EMAIL_INCORRECT	You have specified an incorrect address or the email address does not exist.
	PASSWORD_LOCKED	The password is locked for 60 minutes after 5 failed logon attempts with wrong value.
User Management REST API	PASSWORD_LOCKED	The password is locked for 60 minutes after 5 failed logon attempts with wrong value.
Update Group Resource SCIM REST API	Mismatched group id	The **id of the group** in the URI and the `id` of the group in the request body are different. Make sure that the `id` of the group is one and the same in both places.

Success Codes

Response Code	Meaning	Description
200	OK	Operation successful.
201	Created	Entity created successfully.
204	No Content	The service received and understood the request, but there is no need to send any content back.

Check also the troubleshooting scenarios available in the Guided Answers tool.

See Guided Answers.

Getting Support [page 3141]

1.9.8 Exchanging Identity Authentication Tokens for Tokens from Corporate Identity Providers

This service endpoint returns the tokens issued by the corporate identity provider during the OpenID Connect (OIDC) authentication process. Use this endpoint when you integrate with external applications that don't accept tokens from Identity Authentication and require tokens issued from the corporate identity provider instead.

Prerequisites

- For your business application, there's an OIDC application in Identity Authentication.
  For more information, see Create OpenID Connect (OIDC) Application [page 1925].
- You prepared an authentication credential for the API call for your OIDC application in Identity Authentication. The API supports the following authentication schemes:
  - Basic
  - X.509
  - JWT Bearer

  For more information, see API Authentication [page 1996].
- Your business application has a corporate identity provider as the default identity provider using OIDC.
  For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579] and Choose Default Identity Provider for an Application [page 2067].
- The user has authenticated to this application using Identity Authentication and the corporate OIDC identity provider.

> **Note**
>
> This endpoint works only with a corporate identity provider configured for OIDC. It isn't supported for SAML 2.0 corporate identity providers.

Call Corporate Identity Provider Endpoint

URI: `https://<Cloud Identity Services domain>/oauth2/exchange/corporateidp`

> **Note**
>
> The domain part has the following pattern:
>
> `<tenant ID>.accounts.ondemand.com` or `<tenant ID>.accounts.cloud.sap`. If you have a configured custom domain, the domain has the following pattern: <your custom domain>.
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].

HTTP Method: *POST*

Request Headers

Header	Required	Values
`Content-Type`	Yes	application/x-www-form-urlencoded

Request Parameters

Parameter	Required	Data Type	Description	Parameter Type
`assertion`	Yes	string	Provide the Identity Authentication user token that identifies Identity Authentication session or refresh token.	Request body
`response_type`	No	string	Specifies the token requested from the corporate identity provider. By default, only the `access_token` is requested. Otherwise, you can request the ID token or both. Possible values: • `token` • `id_token` • `token id_token` Separate multiple values with a space ( ).	Request body
`scope`	No	string	Overwrites the default scopes defined in the Corporate IdP configuration. This allows to receive only specific scopes from the IdP.	Request body

Request Example

```
POST /oauth2/exchange/corporateidp
Content-Type: application/x-www-form-urlencoded
Authorization: Bearer eyJbiOi…

response_type=token id_token&
assertion=eyJ0eab…
```

Result

```

Configuring OpenID Connect (OIDC) [page 2636]

1.9.9 Single Logout Flows

Encourage users of your applications to log out at the end of their session. Malicious users can impersonate session owners if they gain access to session data (such as cookies) or find unattended clients.

To counter this threat, ensure that your application participates in single logout (SLO) flows. When users log out from your application, your application notifies Identity Authentication. The service cleans up the user session and triggers logout on any identity providers and applications associated with the session. The service forwards users of your application to a URL.

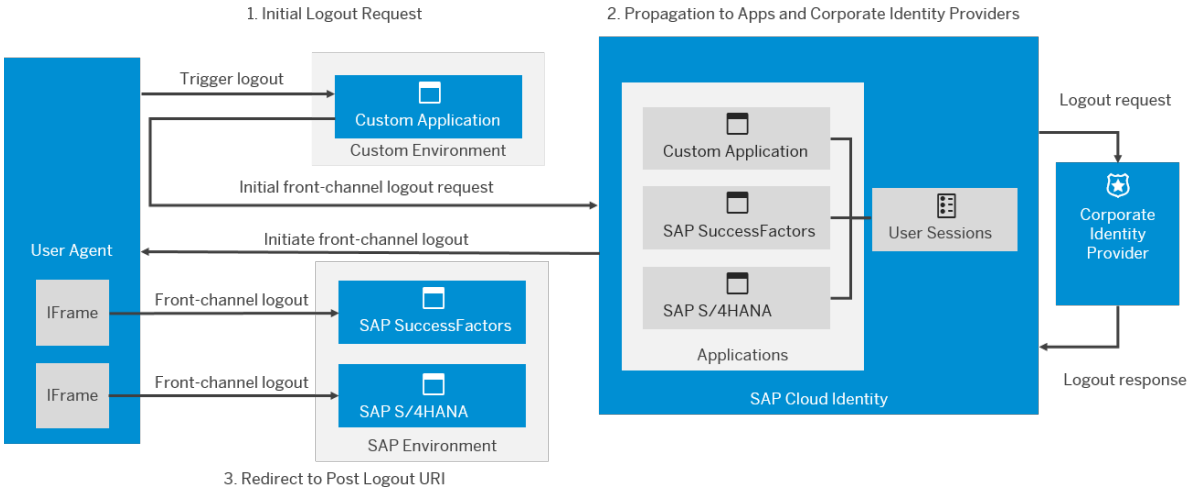
The service supports SAML 2.0 and OIDC logout flows. Regardless of which protocol your applications and identity providers use, the service forwards the logout requests to any corporate identity providers and applications associated with the user session.

> ⓘ Note
>
> SLO ends the sessions of all applications under the same domain as Identity Authentication (`ondemand.com` and `cloud.sap`) and under custom domains configured for the service. To have applications participate in SLO, ensure that the applications operate under these domains (recommended) or allow third-party cookies.

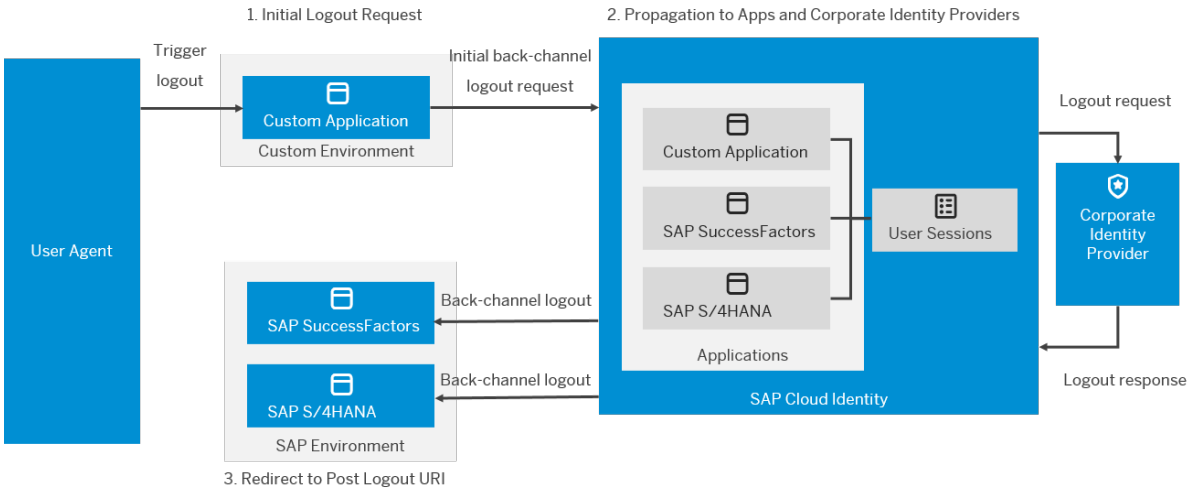
If you define both channels, the system executes both channels.

> → Recommendation
>
> Enabling both channels sends unnecessary messages over the network, since applications only need one logout message. Applications could return unexpected results when they receive a second logout request unless they were designed to handle such requests.
>
> We recommend back-channel logout flows where possible, but applications must be designed to support them.
>
> If you have to manually configure logout flows, check the documentation of your application to determine which logout flows it supports.

The following figures illustrate a logout scenario with multiple applications and a corporate identity provider:



Front-Channel Logout Flow



Back-Channel Logout Flow

- SAML applications: Service Provider-Initiated Logout with Corporate Identity Providers [page 2596]
- OIDC applications: Call Identity Authentication End Session Endpoint [page 2740], Handle Single Logout Request from Identity Authentication [page 2743]
- Cloud Identity Services-initiated SLO: Use IdP-Initiated Single Logout (SLO) [page 2089]

Related Information

Use Custom Domain in Identity Authentication [page 2175]

1.9.10 Consuming APIs from Other Applications

Applications sometimes need to propagate principals or have technical communication arrangements between them. To enable OpenID Connect (OIDC) applications to consume the APIs of other applications, the developer defines API permission groups for a provider application, which a consumer application can consume through a defined dependency.

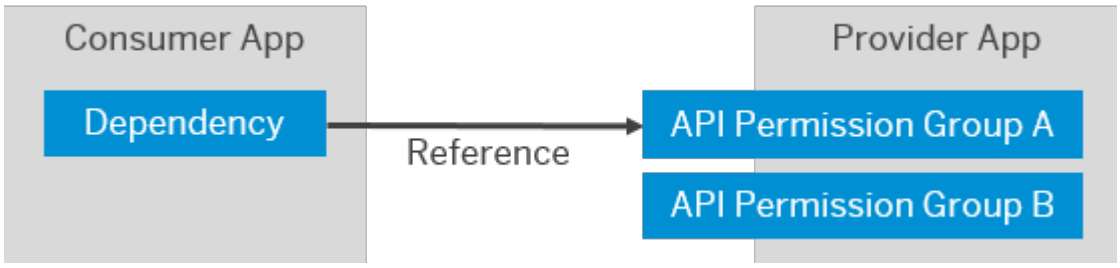
Design Options

In this scenario, you have a provider application that provides a group of APIs and a consumer application that consumes them. Tenant administrators grant access to the consumer applications for this group. You can take one of the following approaches:

- Technical communication that retrieves a new token with a client credential flow
- Principal propagation with a choice between the JWT bearer and token exchange flows

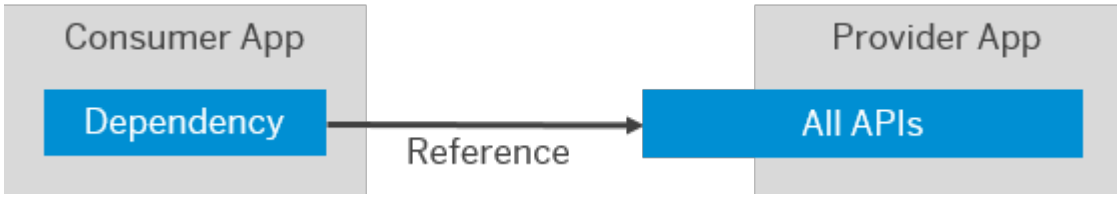
In either case, the audience of the token matches the provider application. In addition, the `ias_apis` claim lists the granted API permission groups or a fixed value for when all APIs are consumed.

The following figure shows the relationship between two applications in SAP Cloud Identity Services. The provider application offers two API permission groups. The dependency of the consumer application refers to one of these groups.



App-to-App Integration of API Permission Groups

Alternatively, if your provider application doesn't need to distinguish different API permission groups and is consumed with principal propagation, you can make all APIs available. The provider application must check the principal propagated by the consumer application for the authorizations required by the APIs. In the following figure, the provider application doesn't offer any API permission groups. The consumer application refers to all the available APIs. The provider application depends on the authorizations of the current user when these APIs are accessed.



App-to-App Integration of All APIs

Configuration Precedence

When you configure both the consumer and provider applications, each application contributes specific OIDC and related configurations. The following table shows which application provides each configuration.

Configuration Source by Application

Configuration	Application	More Information
Subject name identifier	Provider	Configure the Subject Name Identifier Sent to the Application [page 1988]
Token attributes	Provider	User Attributes [page 1972]
Token format	Provider	Token Policy Configuration for Applications [page 2752]
Token grant type	Consumer	Token Policy Configuration for Applications [page 2752]
Token policy	Consumer	Token Policy Configuration for Applications [page 2752]

At Runtime

At runtime, the consumer application fetches a token according to the appropriate flow:

- Use the client credential flow for technical communication.
  For more information, see Using Client Credentials Flow [page 2660].
- Choose the appropriate flow for principal propagation.
  - If the consumer application already issues a JWT token, use the JWT bearer flow.
    For more information, see Using JWT Bearer Flow [page 2689].
  - If the consumer application issues another token type, such as SAML2 assertion to bearer token, use the token exchange flow.
    For more information, see Using Token Exchange [page 2701].

In either case, use the `resource` parameter to identify the dependency consumed by the consumer application. The `resource` parameter is a Uniform Resource Name (URN).

For example: `urn:sap:identity:application:provider:name:<Dependency_name>`

The dependency name is the name that the tenant administrator configures for the dependency between the consumer application and the provider application.

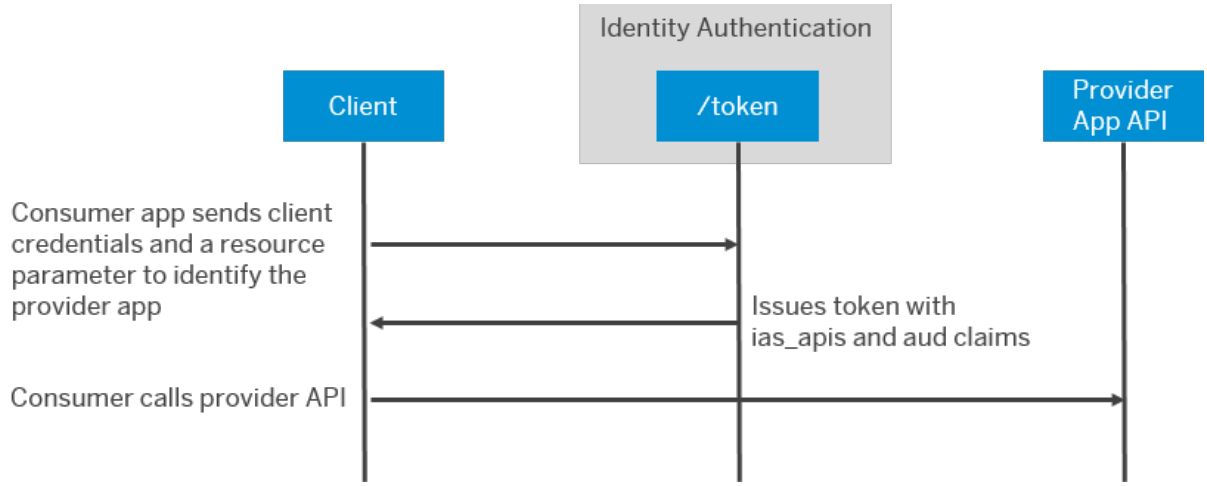
> → Tip
>
> Document the name in a scenario guide so that administrators know which name to use when creating dependencies. If you have experience working with destinations, you're already used to this approach.

In the unusual case that you need a token that reflects multiple dependencies to the same provider application, you can replace `name:<Dependency_name>` with `clientid:<client_id>`. Use the client ID of the provider application in Identity Authentication.

The service returns a token, which includes the following relevant claims:

- The audience (`aud`) claim of the provider application.
- The `ias_api` claim, which includes an array of API permission groups of the provider application.

The consumer application uses this token to call the API endpoint of the provider application. The provider application validates the token and its claims and processes the call. The following figure illustrates this scenario for technical communication between systems.



Technical Communication Sequence Between Applications

Related Information

Provide APIs for Consumption by Other Applications [page 2891]
Consume an API from a Provider Application [page 2893]

1.9.10.1 Provide APIs for Consumption by Other Applications

SAP Cloud Identity Services can help you expose APIs of your application to other applications. You can expose APIs with an API permission group or tie the access to the authorizations of the current user (principal propagation).

Context

You can protect APIs by adding a name for an API permission group. Other applications that are allowed to consume this API permission group pass a token issued by SAP Cloud Identity Services with this name as a claim. Your application must evaluate the `ias_apis` claim for this name to allow access.

If the consuming application is using a principal propagation scenario and not a technical user scenario, your application can check the authorizations assigned to the current user. You can also offer all APIs of the provider application without permission groups. In this case, `principal-propagation` is written in the `ias_apis` claim. Your application must rely on the authorizations available to the current user alone.

As the providing application, you have the following options for configuring identity authentication for API permission groups:

- Use the administration console for SAP Cloud Identity Services as described in the following procedure.
- The provider application can set the API permission groups with the parameters of the Identity service of SAP BTP.
  The following example shows an API permission group named `sales-orders`.

  ```
  "provided-apis": [
    {
      "name": "sales-orders",
      "description": "Access sales orders"
    }
  ]
  ```

  For more information, see Reference Information for the Identity Service of SAP BTP [page 2921].

> → Remember
>
> The provided APIs for the `Administration Console` for Cloud Identity Services is read-only.

Procedure

1. In the administration console for SAP Cloud Identity Services, choose *Applications and Resources* > *Applications*
2. Choose the provider application.
3. Choose the *Trust* tab.
4. Under *Application APIs*, choose *Provided APIs*.
5. Verify that the name of the API permission group that you check in your application is listed.

   Otherwise enter the required data and save your entries.

   > ⚠ Caution
   >
   > The API name must match exactly what is expected by consumer applications. The name must be unique within all APIs provided by the same provider application. Consumer applications use this name to determine if their application has the rights to access the provider application.
   >
   > The name can be any URN-compliant string of up to 50 characters. You can define a maximum of 50 APIs.
   >
   > For more information about URNs, see RFC 8141 .

   To rely solely on the permissions of the current user, select the *Allow all APIs for principal propagation* option. Identity Authentication adds `principal-propagation` to the `ias_apis` claim.

1.9.10.2 Consume an API from a Provider Application

Your consumer application can request an access token from Identity Authentication to consume the API of a provider application.

Prerequisites

You know the name of the dependency defined in the application configuration of SAP Cloud Identity Services. The tenant administrator enters the dependency name in the application configuration. As the owner of the consumer application, you must provide documentation to enable the administrator to do the following:

- Enter the name that you expect.
- Configure the same dependency name in your application.

For more information, see Configure Integration Between Applications [page 2092].

Procedure

1. Develop your consumer application to call the `/oauth2/token` endpoint of Identity Authentication with the dependency name.

   Example: Technical Communication

   A consumer application (client ID 3ab1ba0e-c573-4ad5-20a4-28aa4e587a19) has a dependency to the provider application (client ID 77f42d85-7da7-1aa1-84a2-e65a76308cd3) named **`techDependency`**. The application calls the `/oauth2/token` endpoint with its client ID and the `resource` parameter with the dependency name used to identify the API that the consumer application consumes.

   ```
   curl  $iashost/oauth2/token -X POST \
      -H 'Content-Type: application/x-www-form-urlencoded' \
      -H 'Accept: application/json' \
      -d "client_id=3ab1ba0e-c573-4ad5-20a4-28aa4e587a19" \
      -d "client_secret=$secret" \
      --data-urlencode 'grant_type=client_credentials' \
      --data-urlencode
   'resource=urn:sap:identity:application:provider:name:techDependency'
   ```

   Identity Authentication returns a token with the access control for the APIs and audience claim. The audience claim contains the client ID of the provider application. The following is an example of a token with the relevant claims.

   ```
   {
       "ias_apis": [
           "apiPermissionGroup"
       ],
       "sub": "3ab1ba0e-c573-4ad5-20a4-28aa4e587a19",
       "aud": "77f42d85-7da7-1aa1-84a2-e65a76308cd3",
       "azp": "3ab1ba0e-c573-4ad5-20a4-28aa4e587a19",
   }
   ```

Example: Principal Propagation:

A consumer application (client ID e7c7e327-86c0-48a6-af57-a1234b567869) has a dependency to the provider application (client ID 7ab2cd3e-c573-4ad5-9007-28aa4e587a19) named **`myDependency`**. The application calls the `/oauth2/token` endpoint with its client ID and the `resource` parameter with the dependency name used to identify the API that the consumer application consumes.

```
curl $iashost/oauth2/token  -X POST \
    -H 'Content-Type: application/x-www-form-urlencoded' \
    -H 'Accept: application/json' \
    -d "client_id=e7c7e327-86c0-48a6-af57-a1234b567869" \
    -d "client_secret=$secret" \
    -d "grant_type=urn%3Aietf%3Aparams%3Aoauth%3Agrant-type%3Ajwt-bearer" \
    -d "assertion=$BEARERTOKEN" \
    -d "resource=urn:sap:identity:application:provider:name:myDependency"
```

Identity Authentication returns a token with the access control for the APIs and audience claim. The audience claim contains the client ID of the provider application. The following is an example of a token with the relevant claims.

```
{
    "ias_apis": [
        "apiPermissionGroup"
    ],
    "sub": "P123456",
    "mail": "donna.moore@example.com",
    "last_name": "Moore",
    "aud": "7ab2cd3e-c573-4ad5-9007-28aa4e587a19",
    "scim_id": "1a2345bc-4f6b-456b-9bfb-5d58beb97fb7",
    "user_uuid": "1a2345bc-4f6b-456b-9bfb-5d58beb97fb7",
    "azp": "e7c7e327-86c0-48a6-af57-a1234b567869",
    "first_name": "Donna",
    …
}
```

2. Send the token to the API endpoint of the provider application.

Related Information

Consuming APIs from Other Applications [page 2889]

1.9.10.3 Consume APIs from the Administration Console

Your consumer application can request an access token from Identity Authentication to consume the APIs of the Administration Console for Cloud Identity Services acting as a provider application.

Prerequisites

You have configured the integration between the `Administration Console` application in the tenant and your consumer application that will use the APIs of the `Administration Console`. For more information, see Configure Integration Between Applications [page 2092].

Context

Cloud Identity Services have exposed the Identity Directory API, Corporate Identity Providers API, and SAP Cloud Identity Services Application Directory as provided APIs for the Administration Console application. These APIs can be used for principal propagation. For more information, see Consuming APIs from Other Applications [page 2889].

> **Note**
>
> Tenant administrators with **Manage Users** and **Manage Groups** roles have full access to the Identity Directory API. For all other users, the Identity Directory API supports *GET* and *PATCH* operations about the user for whom the token is issued, and the following attributes of the user can be returned or updated:
>
> - `urn:ietf:params:scim:schemas:core:2.0:User:locale`
> - `urn:ietf:params:scim:schemas:extension:sap:2.0:User:localeSettings.currency`
> - `urn:ietf:params:scim:schemas:extension:sap:2.0:User:termsOfUse`
> - `urn:ietf:params:scim:schemas:extension:sap:2.0:User:privacyPolicy`

Procedure

1. Develop your consumer application to call the `/oauth2/token` endpoint of Identity Authentication with the respective dependency name.

   > **Note**
   >
   > The available names are: `scim`, `identityproviders`, `applications`.

   Example: Principal Propagation:

   A consumer application (client ID 8bbc6f92-0222-46f1-b9c5-b2b48825e78b) has a dependency to the Administration Console application acting as a provider application (client ID 09b90b70-3e4c-4fbc-b4ac-

ef66848b7fbc) named **`applications`**. The application calls the `/oauth2/token` endpoint with its client ID and the `resource` parameter with the dependency name used to identify the API that the consumer application consumes.

```
curl $iashost/oauth2/token  -X POST \
                        -H 'Content-Type: application/x-www-form-urlencoded' \
                        -H 'Accept: application/json' \
                        -d "client_id=8bbc6f92-0222-46f1-b9c5-b2b48825e78b" \
                        -d "client_secret=$secret" \
                        -d "grant_type=urn%3Aietf%3Aparams%3Aoauth%3Agrant-
type%3Ajwt-bearer" \
                        -d "assertion=$BEARERTOKEN" \
                        -d
"resource=urn:sap:identity:application:provider:name:applications"
```

Identity Authentication returns a token with the access control for the API and audience claim. The audience claim contains the client ID of the provider application. The following is an example of a token with the relevant claims.

```
{
                            "ias_apis": [
                            "applications"
                            ],
                        "sub": "P123456",
                        "mail": "donna.moore@example.com",
                        "last_name": "Moore",
                        "aud": "09b90b70-3e4c-4fbc-b4ac-ef66848b7fbc",
                        "scim_id": "1a2345bc-4f6b-456b-9bfb-5d58beb97fb7",
                        "user_uuid": "1a2345bc-4f6b-456b-9bfb-5d58beb97fb7",
                        "azp": "8bbc6f92-0222-46f1-b9c5-b2b48825e78b",
                        "first_name": "Donna",
                        …
                        }
```

2. Send the token to the API endpoint of the provider application.

Related Information

Consuming APIs from Other Applications [page 2889]

1.10 Security

This section describes the security features of SAP Cloud Identity Services.

In this section:

- Security Information [page 2897]
- Data Protection and Privacy [page 2901]

1.10.1 Security Information

This document is an overview of security-relevant information that applies to Identity Authentication, and contains recommendations about how administrators should secure it.

While this document is intended to support administrators and security responsible specialists to use Identity Authentication in a secure manner, there may be further elements to consider depending on usage, integrations as well as applicable industry or local legal regulations.

Updates and Notifications

For more information, see Updates and Notifications [page 3142].

Before You Start

Before you secure Identity Authentication, protect the cloud application that trusts Identity Authentication. For more information about protecting SAP BTP applications, see Security, Neo Environment.

Security Recommendations

SAP BTP Security Recommendations collects information which helps you to secure the configuration and operation of SAP BTP services in your landscape.

For more information, see Security Recommendations - Identity Authentication and Security Recommendations - Identity Provisioning and Monitoring with SAP Cloud ALM [page 2991].

Communication Protocol

Identity Authentication is fully web browser based application, with all access over HTTPS. Every page of the Identity Authentication application is currently delivered via Transport Layer Security (TLS). Access to Identity Authentication is encrypted-in-transit over HTTPS using 256-bit TLS encryption.

By default, the Identity Provisioning uses secure communication channels. Still, when connecting to customer systems, you decide (define) what the communication channel to be.

Recommendations

- Always use secure protocols when specifying your connection details (in the cockpit → *Destinations* section, in the Identity Provisioning UI → *Properties* tab).
- Always re-enter the values of the configured credential properties when you update the **URL** or host name of an existing provisoning system in the *Properties* tab of the Identity Provisioning UI. The only exception to this are the credential properties of systems that are created with a connectivity destination.

- Avoid using property `TrustAll` in productive scenarios. When it's set to **true**, the SSL server certificate is not verified, and thus the server is not authenticated.

User Administration

Set user permissions in accordance with the scenario you are configuring. For more information, see Scenarios [page 544].

You have the following options:

- For a business-to-consumer scenario, allow *Public* user application access.
- For a business-to-business scenario, allow *Private* user application access.
- For a business-to-employee scenario, allow *Internal* user application access.

For more information about the settings for user application access, see Configure User Access to the Application [page 2025].

You can also define rules for authentication according to different risk factors. For more information, see Configure Risk-Based Authentication for an Application [page 2007].

User Authentication

Identity Authentication protects your users during authentication in the following ways:

- With SAML 2.0 or OpenID Connect
  Identity Authentication supports the single sign-on (SSO) mechanism. Every user with an account is able to use SSO for the cloud applications that use Identity Authentication.
- With an application certificate
  The Identity Authentication authentication interfaces that receive REST API calls are protected, since they require an application certificate. Use the certificate when implementing REST APIs for your application. For more information, see the REST API configurations in Development [page 2779].

Authorizations

Applications configured in Identity Authentication can manage business user authorizations for applications. For such applications, the *Authorization* tab shows a list of authorization policies created by the application. You can also create custom authorization policies. These authorization policies are stored as user groups. You can assign authorization policies to business users with the admin console, but you can also use a SCIM API.

Password Security

Identity Authentication does not store plain text passwords in the database, but only their iterated random-salted secure hash values. The random salt is at least 512 bits, and it is different for each password. Only

generic hash functions are used with minimum 512 bits key length. No default passwords are delivered, used, or accepted anywhere.

Identity Authentication can use also passwords from on-premise systems for user authentication. These passwords are not stored by Identity Authentication. It sends the user ID and the password for authentication to the on-premise system via the Transport Layer Security (TLS) connection. The management of these passwords depends on the integrated on-premise system that supports them, for example Microsoft Active Directory.

Identity Authentication supports three levels of password security. You should use the highest level of security that matches the requirements of your application. The passwords are managed based on password policy rules. For more information, see Configuring Password Policies [page 2223].

Encryption

When using Identity Provisioning to configure a provisioning system, always set credentials (such as passwords, private keys and OAuth secrets) as *Credential* properties. When you add a credential property, its value is displayed as an encrypted string. For better security, the encrypted string is always displayed as 40 characters, no matter how long your real password is.

Session Security

Session cookies in Identity Authentication are protected with a Transport Layer Security (TLS) and with the *Secure* and *HttpOnly* attributes. You don't need to make any additional configurations for Identity Authentication.

Network and Communication Security

Identity Authentication is setup in a fenced network, separated from the SAP internal network.

Customer applications run in a shared environment where the business data is isolated from each other, the SAP BTP services uses a shared SAP BTP infrastructure. The internal traffic is controlled by firewalls. SAP administrative access is done via terminal service that requires strong authentication.

All communication channels are protected with TLS, and you should configure the cloud application to use TLS and to check the SAML 2.0 signature.

Data Storage Security

Data storage security is about how Identity Authentication protects its own database. Data storage security is ensured by the isolated tenant that each customer receives. Only tenant-specific requests can access the tenant's database. These requests are performed by a tenant service, which works with a dependency injection

framework and makes sure that all the services, for example the persistence service and the mail service, are injected with the instances dedicated to the given tenant.

In Identity Provisioning, no personal or sensitive information about the provisioned entities is saved. To check whether any changes have been made to an entity after the initial provisioning, Identity Provisioning uses strong hashed algorithm for the provisioned entities.

If a provisioning job repeatedly fails and you need problem investigation, you can enable detailed entity tracing. That means, the Identity Provisioning service will log the complete information (general, personal and sensitive data) of your provisioned entities. For example, if *"groups": XXX* are not an array but have a string value instead; or an attribute that must have a string value, has an integer value instead. Tracing such data could help you identify potential incorrect attribute values for a certain entity, which you can correct in the source system or via the transformation functions.

To activate entity tracing, proceed as follows:

1. In your source system, set property **ips.trace.failed.entity.content** to *true*.
2. Run again the provisioning job.
3. Open the *Job Logs* section, select your job, and under *Failed Entities*, choose an entity and find the log information about it.
4. If you cannot resolve the problem, contact the Identity Provisioning support.

> **Note**
>
> The operators may need the full trace content, so they can ask you to set the property in your target system as well, and once again run the provisioning job.

Security-Relevant Logging and Tracing

You can download a CSV file with a history of operations performed by administrators. For more information, see Export Change Logs with a History of Administration Operations [page 2976].

You can retrieve the statistics on the number of user logon request per month. This number is counted on each single authentication managed via Identity Authentication. For more information, see View Usage Statistics [page 2966].

1.10.2 Data Protection and Privacy

Governments place legal requirements on industry to protect data and privacy. We provide features and functions to help you meet these requirements.

> ⓘ Note
>
> SAP does not provide legal advice in any form. SAP software supports data protection compliance by providing security features and data protection-relevant functions, such as blocking and deletion of personal data. In many cases, compliance with applicable data protection and privacy laws is not covered by a product feature. Furthermore, this information should not be taken as advice or a recommendation regarding additional features that would be required in specific IT environments. Decisions related to data protection must be made on a case-by-case basis, taking into consideration the given system landscape and the applicable legal requirements. Definitions and other terms used in this documentation are not taken from a specific legal source.

Handle personal data with care. You as the data controller are legally responsible when processing personal data. It is not permitted to deal with sensitive personal data in Identity Authentication.

> → Remember
>
> Custom attributes must not be used to store sensitive personal data. For more information, see Configuring User Attributes from the Identity Directory [page 1973].

Glossary for Data Protection and Privacy [page 2902]
The following terms are general to SAP products. Certain terms might not be relevant for Identity Authentication.

Change Logging and Audit Logging [page 2904]
Change logging records changes to personal data, while audit logging provides access to personal data, successful, and failed authentications. You may be required to gather this information for auditing purposes or legal requirements.

Information Report [page 2904]
An information report is a collection of data relating to a data subject. A data privacy specialist may be required to provide such a report or an application may offer a self-service.

Erasure [page 2905]
When handling personal data, consider the legislation in the different countries where your organization operates. After the data has passed the end of purpose, regulations may require you to delete the data. However, additional regulations may require you to keep the data longer. During this period, you must block access to the data by unauthorized persons until the end of the retention period, when the data is finally deleted.

Consent [page 2906]
We assume that software operators, such as SAP customers, collect and store the consent of data subjects, before collecting personal data from data subjects. A data privacy specialist can later determine whether data subjects have granted, withdrawn, or denied consent.

Customer Data [page 2906]

1.10.2.1 Glossary for Data Protection and Privacy

The following terms are general to SAP products. Certain terms might not be relevant for Identity Authentication.

Term	Definition
Blocking	A method of restricting access to data for which the primary business purpose has ended.
Business purpose	A legal, contractual, or in other form justified reason for the processing of personal data. The assumption is that any purpose has an end that is usually already defined when the purpose starts.
Consent	The action of the data subject confirming that the usage of his or her personal data shall be allowed for a given purpose. A consent functionality allows the storage of a consent record in relation to a specific purpose and shows if a data subject has granted, withdrawn, or denied consent.
Deletion	Deletion of **personal data** so that the data is no longer available.
End of business	Date where the business with a data subject ends, for example the order is completed, the subscription is canceled, or the last bill is settled.
End of purpose (EoP)	End of purpose and start of blocking period. The point in time, when the primary processing purpose ends (for example contract is fulfilled).
End of purpose (EoP) check	A method of identifying the point in time for a data set when the processing of **personal data** is no longer required for the primary **business purpose**. After the **EoP** has been reached, the data is **blocked** and can only be accessed by users with special authorization (for example, tax auditors).
Personal data	Any information relating to an identified or identifiable natural person ("data subject"). An identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more factors specific to the physical, physiological, genetic, mental, economic, cultural, or social identity of that natural person
Purpose	The information that specifies the reason and the goal for the processing of a specific set of personal data. As a rule, the purpose references the relevant legal basis for the processing of personal data.

Term	Definition
Residence period	The period of time between the end of business and the end of purpose (EoP) for a data set during which the data remains in the database and can be used in case of subsequent processes related to the original purpose. At the end of the longest configured residence period, the data is blocked or deleted. The residence period is part of the overall retention period.
Retention period	The period of time between the end of the last business activity involving a specific object (for example, a business partner) and the deletion of the corresponding data, subject to applicable laws. The retention period is a combination of the residence period and the blocking period.
Sensitive personal data	A category of personal data that usually includes the following type of information: • Special categories of personal data, such as data revealing racial or ethnic origin, political opinions, religious or philosophical beliefs, trade union membership, genetic data, biometric data, data concerning health or sex life or sexual orientation. • Personal data subject to professional secrecy • Personal data relating to criminal or administrative offenses • Personal data concerning insurances and bank or credit card accounts
Where-used check (WUC)	A process designed to ensure data integrity in the case of potential blocking of business partner data. An application's where-used check (WUC) determines if there is any dependent data for a certain business partner in the database. If dependent data exists, this means the data is still required for business activities. Therefore, the blocking of business partners referenced in the data is prevented.

1.10.2.2 Change Logging and Audit Logging

Change logging records changes to personal data, while audit logging provides access to personal data, successful, and failed authentications. You may be required to gather this information for auditing purposes or legal requirements.

Audit Logs

Tenant administrators can access the audit logs for changes in the personal data, successful, and failed authentications in Identity Authentication. If you want to view the audit logs, you should generate Client ID and Client Secret for audit logs in the administration console for SAP Cloud Identity Services, obtain an access token, and call the audit log retrieval API to access the data. For more information, see Access Audit Logs (Audit Log Service in SAP BTP, Neo) [page 2972].

The audit log entries are retained for:

- SAP BTP, Cloud Foundry environment (for tenants on the AWS and Azure infrastructure.) - 90 days
- SAP BTP, Neo environment (for tenants on the SAP infrastructure)- 201 days

Change Logs

Tenant administrators can access information about configuration changes made by administrators in Identity Authentication. You can download a CSV file with a history of the operations performed by administrators. The change logs are stored in the data base for 24 months. For more information, see Export Change Logs with a History of Administration Operations [page 2976].

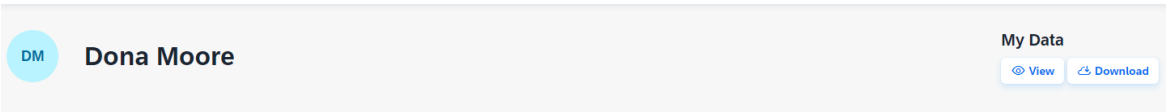
1.10.2.3 Information Report

An information report is a collection of data relating to a data subject. A data privacy specialist may be required to provide such a report or an application may offer a self-service.

Information About Own Personal Data

Data subjects can obtain information about their personal data in Identity Authentication, via the profile page at https://<tenant ID>.accounts.ondemand.com/.

- Users can open an overview of all the data for them by visiting their account and chosing the *View* button under the *My Data* section on the screen.



> ### Note
>
> The data includes the **Terms of Use** and **Privacy Policy** documents singed by the user. The documents can be seen by clicking on their names. They open in a new tab.

- Users can download an overview of all the data for them on a JSON file by clicking the *Download* button in the *My Data* section.

Information About Users' Data

Tenant administrators can view detailed information about the users in the administration console for SAP Cloud Identity Services. Optionally they can edit this information. For more information, see List and Edit User Details [page 2361].

> ### Note
>
> Currently, the Information Report is not applicable for Identity Provisioning.

The Identity Provisioning only transfers entities from a source system to a target one. The applications representing these source and target systems may provide data about the provisioned entities but this data is only stored in the systems, not in the Identity Provisioning itself.

1.10.2.4 Erasure

When handling personal data, consider the legislation in the different countries where your organization operates. After the data has passed the end of purpose, regulations may require you to delete the data. However, additional regulations may require you to keep the data longer. During this period, you must block access to the data by unauthorized persons until the end of the retention period, when the data is finally deleted.

Only the service provider is aware of the retention policies of the user, and thus whether a user record has to be blocked first, and deleted at a certain time in the future, or whether a user record can be deleted immediately.

The end user who wants to cancel his or her registration from the service should start the process via the service provider, not via Identity Authentication. Identity Authentication keeps user information for every service provider. Each service provider deletes its specific data stored about the user in Identity Authentication via an API call. If the user has accounts in more than one service provider, his or her whole user profile in Identity Authentication is deleted when the information for the last service provider is deleted. For more information, see SP User Deletion [page 2817].

Apart from deleting, users can be blocked. When users are blocked, they exist in Identity Authentication, but cannot be authenticated when they try to log on. For more information, see SP User Deactivation [page 2815].

Tenant administrators can delete and block users via the administration console for SAP Cloud Identity Services. For more information, see Delete Users [page 2367] and Deactivate Users [page 2368].

Tenant administrators can also configure blocking and deletion for specific user types and after certain period of time, For more information, see Block or Delete Users Due to Inactivity [page 2366].

1.10.2.5 Consent

We assume that software operators, such as SAP customers, collect and store the consent of data subjects, before collecting personal data from data subjects. A data privacy specialist can later determine whether data subjects have granted, withdrawn, or denied consent.

Every (service provider) application that trusts Identity Authentication can configure its own privacy policy and terms of use documents. For more information, see Configuring Privacy Policies [page 2235], and Configuring Terms of Use [page 2273].

Identity Authentication takes care the documents to be accepted by the users. Whenever a new version of the document becomes available, an upgrade process is started.

The end users can view the signed **Terms of Use** and **Privacy Policy** documents by them at the profile page. For more information, see Information Report [page 2904].

The tenant administrators can view a history of the signed **Terms of Use** and **Privacy Policy** documents of the users in the administration console for SAP Cloud Identity Services. The information is in the format *<document name><document version><time stamp>*.

> **Note**
>
> The information about when the user has accepted a particular document is available for documents accepted after May 16, 2018.

To view that information, access *Administration Console* > *Users & Authorizations* > *User Management* > *User Name* > *Legal tab*. For more information about how to view the user information in the administration console, see List and Edit User Details [page 2361].

1.10.2.6 Customer Data

Customer can request export of its customer data in a JSON format by reporting an incident on SAP Support Portal Home with a component `BC-IAM-IDS`. The request can be for full data export or selected data export according to the customer requirements.

When using Identity Provisioning, you can clear the customer data (systems, jobs, execution logs). You need to sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Tenant Reset*. For more information, see Reset Identity Provisioning Settings [page 2484].

1.10.3 Auditing and Logging Information

Here you can find a list of the security events that are logged by Identity Authentication.

Security events written in audit logs

Event grouping	What events are logged	How to identify related log events	Additional information
Authentication	All authentication and authorization checks.	`audit.authentication`	Formatting each log in key-value pairs simplifies a lot displaying logs in systems, searching by predefined key or value, downloading logging files, etc. In the Identity Authentication audit logging interface, the following log content is available: Caller `<caller>` did action `<action>` related to objectType `<objectType>` with unique identifier `<objectId>`. The result of this action is state `<state>` which is caused by cause `<cause>` and the message is `<message>`. Each audit log entry consists of the following key-value pairs: • state* = [successful | aborted | failed | ignored | process] • action* = [create | update | search | delete | upsert | add | validate | validate_sms_code | reset | export | import | verifyPhone | testConnection | read | restore | upload | list | provision | login | authenticate | logout | sendMail(s) | passwordCheck | load | rbaRuleCheck | otpCodeCheck | authenticityCheck | grantPermissions | count | setOtpAttributes | getStatistics | getUsage | setAttributes | provisionAllUsers | provisionUser(s) | forgotPassword | setIni-
Configuration	All property/properties of an entity that presents kind of configuration changes that affect the system behavior.	`audit.configuration`	
Data Change	All attribute/attributes of an entity changes.	`audit.data-change`	

Event grouping	What events are logged	How to identify related log events	Additional information
Change Logs	All attribute/attributes of change logs.	audit.config-change	tialPassword | process | setConsolidationStatus | mark | sendSmsCode | issueAssertion | issueAuthorizationCode | issueJwtToken | linkUser | returningConsolidationStatus | returnungResetPasswordStatus] • objectType* = [company | tenant(s) | tenantAdmin | serviceProvider(s) | identityProvider(s) | socialProvider(s) | service | scimGroup(s) | passwordPolicy(ies) | provisioningSystem(s) | allProvisioningSystems | user(s) | spUser |group(s) | thing(s) | contact | emailTemplates | resource | tenantLogo | scimConfiguration | smsConfiguration | spnegoConfiguration | termsOfUse | privacyPolicy | tenantSettings | trustedDomain(s) | tenantSamlConfiguration | auditLogClients | scimUser(s) | otpCode | forgotPasswordMailCounter | cockpit | usageStatistics | activityAggregator | corporateUserStore | channel | token | trustedIdp | newSpSession | activeSpAndIdpSessions | rbaAction | tenantRbaConfiguration I socialIdentity | openIdClient | googleRecaptcha | companyGroup | psrMailService | entity.Policy | entity.UserPolicy]

Event grouping	What events are logged	How to identify related log events	Additional information
			• objectId* = [unique attribute of the objectType – either id, or name, etc...] • caller = [The identifier of the subject] • cause = [callerUnauthorized | userNotFound | validationFailure, interrupted, otpCheckFailure, passwordCheckFailure | mailNotVerified | notSupported | alreadyUsed | maximumNumberReached | invalidCode | thirdInvalidCode | alreadyInUse | missingUserPassword | missingTargetSystemConfig] • message = [Exception message or additional message which specifies the result of the action] • category* = [audit.authentication | audit.configuration | audit.dataChange] • additionalAttributes – key-value formatted attributes which are specific for each objectType • all change log resource types **Note** * Available in each log entry.

1.11.1 Integrating the Service with SAP Business Technology Platform, Neo Environment

SAP BTP acts as a service provider, and Identity Authentication acts as an identity provider in this setup.

Context

> **Note**
>
> The content in this section is only relevant for SAP BTP, Neo environment.

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

For the integration, you must set the trust on both SAP BTP and Identity Authentication. As a result of the trust setting, when you have deployed an application to SAP BTP that has protected resources and requires SAML authentication, the user is redirected to the logon page of Identity Authentication to provide credentials.

> **Note**
>
> Once setting Identity Authentication as a trusted identity provider for SAP BTP all the services in the SAP BTP would be authenticated via Identity Authentication. For more information about the services provided by SAP BTP, see Services.

For the integration you need to make configurations in the cockpit of SAP BTP and in the administration console for Identity Authentication. The configurations made in the administration console do not affect the authentication for the cockpit, which is carried out via the SAP-defined tenant, SAP ID service.

> **→ Tip**
>
> If you want to use a custom Identity Authentication tenant as an identity provider for the cockpit, see Platform Identity Provider (for the cockpit or console client).

For more information about the access to SAP BTP and Identity Authentication, see the following sections:

- Access to SAP BTP Cockpit
- Access to Identity Authentication

Task overview: Integrating the Service [page 2910]

Blogs [page 2964]

Access to SAP BTP Cockpit

Once you purchase a customer or partner account of SAP BTP, an email is sent to the contact person from your company with a link to your SAP BTP cockpit. The contact person is specified in the Order Form for SAP Cloud Services. He or she is the first subaccount member of the SAP BTP cockpit.

> ⓘ Note
>
> For more information how to add other users for the subaccount, see Managing Members in the Neo Environment

The cockpit is the central point for managing all activities associated with your cloud-based business applications. For more information about the cockpit, see Cloud Cockpit.

To deploy applications on SAP BTP and to make configurations in the cockpit, you need a subaccount that corresponds to your role. For more information, see Getting a Global Account.

Access to Identity Authentication

Identity Authentication does not use for authentication the users registered in the SAP Service Marketplace, but maintains an own user store for administrators and users.

Once you purchase a customer or partner account of SAP BTP, a user account for Identity Authentication is created for the same contact person, specified in the Order Form. The contact person is the first administrator in the administration console for Identity Authentication. He or she receives an activation email for the administration console account. The subject of the email is: *Activate Your Account for Administration Console*. Following the required steps, the administrator activates the account and can continue to the administration console for SAP Cloud Identity Services via the console's URL.

> ⓘ Note
>
> The URL has the `https://<tenant ID>.accounts.ondemand.com/admin` pattern.
>
> *Tenant ID* is an automatically generated ID by the system. The URL is in the activation email received by the first administration contains the *tenant ID*.

> ⚠ Caution
>
> If new SAP BTP members are added into the Members page of the SAP BTP cockpit these members are not added as administrators of Identity Authentication. This is done only for the first account member. For more information about how to add new administrators in Identity Authentication, see Add User as Administrator [page 2304].

1.11.1.1 Configure SAP BTP

Prerequisites

- You have a subaccount for SAP BTP.
  For more information, see Getting a Paid Enterprise Global Account.
- You have a tenant of Identity Authentication.
- You have protected your SAP BTP application.
  For more information about how to protect your resource, see Enabling Authentication.

> **Note**
>
> If you want to use SAP BTP in a productive environment, you should purchase a customer account or join a partner account. The free tier model for SAP BTP uses the default SAP tenant.
>
> By default, SAP BTP uses `SAP ID service` as a trusted identity provider. `SAP ID service` is an SAP-defined tenant that cannot be configured by external administrators. If your environment contains SAP applications such as SAP Jam, SAP Community Network or Success Map that use authentication through `SAP ID service`, you can use the default tenant.

Context

You have two configuration options based on the following cases:

You want to	Procedure
Add a tenant of Identity Authentication registered for your company or organization as an identity provider.	Follow the procedure in: Identity Authentication Tenant as an Application Identity Provider. **Note** In this case, the trust is established automatically upon registration in both the SAP BTP and the Identity Authentication tenant. Automatically the SAP BTP Account is registered as an application in the tenant of Identity Authentication. You can find it in the administration console under the *CUSTOM APPLICATIONS* list, representing your SAP BTP account.

You want to	Procedure
Configure manual trust	1. Download the metadata file of Identity Authentication. For more details, see: Tenant SAML 2.0 Configurations [page 2103]. 2. Use this metadata to configure the trust on SAP BTP. For more details about this configuration, see Application Identity Provider.

→ Tip

Once setting Identity Authentication as a trusted identity provider for SAP BTP all SAP BTP applications and services use the trust and configuration settings. If you need different settings for the different SAP BTP applications or services, open a new subaccount. For more information, see Create Subaccounts. Once you have created the new subaccount, add the tenant of Identity Authentication in the new subaccount. Repeat the procedure from the table above to set the trust for each subaccount.

1.11.1.2 Configure Identity Authentication

Prerequisites

- You have a tenant of Identity Authentication.
- You have added the tenant of Identity Authentication as an identity provider in SAP BTP cockpit. For more information, see: Identity Authentication Tenant as an Application Identity Provider.
- You have downloaded the metadata for SAP BTP as a service provider (SP). For more information, see Application Identity Provider.

Context

You need this configuration if you have added a tenant of Identity Authentication which is not registered for the organization or company for which the SAP BTP account is created.

If you have added a tenant of Identity Authentication registered for your company or organization as an identity provider, see Configure SAP BTP [page 2913].

Procedure

1. Set the trust with SAP BTP. For more details, see Configure Trust [page 1941]
2. **Optional:** Customize the settings for the application. For more information, see Configuring Applications [page 1920].

1.11.1.3 Configure IdP-Initiated SSO with SAP BTP

Context

You can perform IdP-initiated single sign-on (SSO) in SAP BTP by sending the SAML Response directly to the application URL that is protected with SAML. This requires you to change the assertion consumer service (ACS) endpoint on the identity provider side to point to this URL.

To configure IdP-initiated SSO with SAP BTP, follow the steps below:

Procedure

1. Change the ACS endpoint on the identity provider side to point to the application protected URL. For more information, see Step 6 in Configure Trust [page 1941].
2. Configure IdP-initiated SSO. For more information, see Configure IdP-Initiated SSO [page 2201].

1.11.1.4 Configure User Attributes Mapping

You have to specify how the user attributes are sent to SAP BTP in the assertion, and define their mapping.

1. Configure User Attributes in Identity Authentication

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose your SAP BTP application from the list.
4. Choose the *Trust* tab.

5. Under *SINGLE SIGN-ON*, choose *Attributes*.
6. Configure the attributes.
7. Save your configuration.

   If the operation is successful, you receive the message `Attributes updated`.

Related Information

Configuring User Attributes from the Identity Directory [page 1973]

2. Configure Mapping in SAP BTP

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. Select the subaccount and choose *Trust* in the navigation bar.
3. Choose the *Application Identity Provider* > *the identity provider that the platform uses for authentication* .
4. Choose *Attributes* > *Add Assertion-Based Attribute* .
5. Enter the fields as follows:

Assertion Attribute	Principal Attribute
*	*

> **Note**
>
> This specifies that all assertion attributes will be mapped to the corresponding principal attributes without a change
>
> The *Assertion Attribute* field is for the attribute that comes from the assertion.
>
> The *Principal Attribute* field is the user attribute that the users will have at SAP BTP.

6. Save your changes.

Related Information

Application Identity Provider

1.11.1.5 Configure SAP BTP Custom Domains

You can make your SAP BTP applications accessible on your own domain different from hana.ondemand.com - for example www.myshop.com.

Prerequisites

You have configured your application's custom domain using the SAP BTP console client. For more information, see Configuring Custom Domains.

Context

When a custom domain is used, both the domain name and the server certificate for this domain are owned by the customer.

To use a custom domain for the application that uses your Identity Authentication tenant for authentication, follow the procedure as described in the current document.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the list item of the application that will use a custom domain.
4. Choose the *Trust* tab.
5. Under *SAML 2.0*, choose *SAML 2.0 Configuration*.
6. Edit the *Assertion Consumer Service Endpoint* URL field and the *Single Logout Endpoint* URLs fields by replacing `authn.hana.ondemand.com` with your custom domain name. In the example above,this would be `www.myshop.com`.
7. Save your changes.

Results

Once the configuration has been changed, the system displays the message `Application <name of application> updated`. The application can only be accessed via the custom domain.

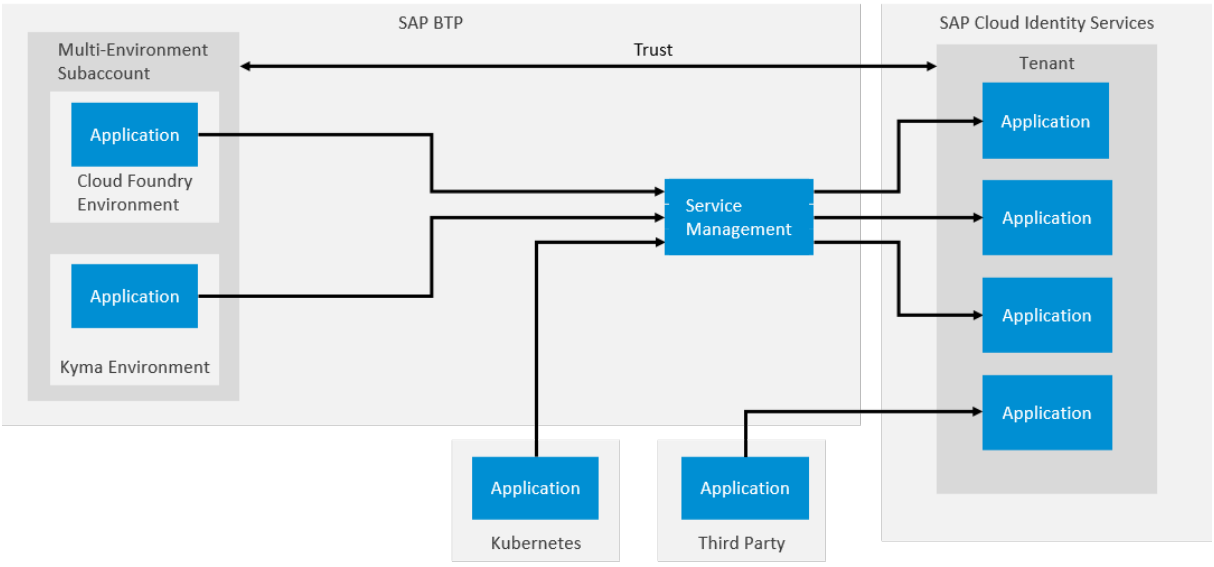
1.11.2 Integrating the Service with the Identity Service of SAP BTP

The Identity service of SAP BTP enables you to delegate authentication and authorization to Cloud Identity Services. When you register an application, the Identity service automatically creates an OpenID Connect (OIDC) application in Cloud Identity Services.

The Identity service of SAP BTP enables you to realize authentication for applications built with SAP BTP regardless of whether your application resides in an environment of SAP BTP or not. While you can manually configure an application of Cloud Identity Services to serve the function of an OIDC provider, the Identity service automates this process. You can preconfigure aspects of the Cloud Identity Services application, such as the display name of the application and redirect URIs. The Identity service enables an application to exchange information such as URL and credentials with the application of the Cloud Identity Services tenant.

This integration supports principal propagation to services consumed by your application.

The following figure shows each application integrating with the Cloud Identity Services tenant linked to your subaccount. The Identity service instance is represented by an application in the Cloud Identity Services tenant.



Applications Using the Identity Service

Each Identity instance has its own OAuth client for the Cloud Identity Services application serving as the OAuth and OIDC server. The OAuth client has its own credentials; either client ID and client secret or X.509 certificate. To use an existing X.509 client certificate from a trusted Certification Authority, provide the certificate when binding the instance to your application. Alternatively, you can request a new certificate as part of the binding. Access these credentials from the service binding. No matter which type of credentials you use, the Identity service supports code flows for users and technical users.

> ### Note
>
> The credentials only enable you to request a token and not use any other APIs of the Cloud Identity Services.

Reference Information for the Identity Service of SAP BTP [page 2921]

1.11.2.1 Getting Started with the Identity Service of SAP BTP

To create OpenID Connect (OIDC) applications in the Cloud Identity Services service using SAP Cloud Service Management service, instantiate the Identity service and bind your service instance to an application. The Identity service automates the manual creation of Cloud Identity Services OIDC applications.

Prerequisites

- You've established trust between your subaccount and your tenant of the Cloud Identity Services service using OpenID Connect.
  For more information, see Establish Trust and Federation Between UAA and Identity Authentication Service.
- You've prepared your application to consume the services of SAP BTP
  For more information, see Consuming Services in Other Environments Using the Service Management Instances.

Context

You can use Service Manager capabilities to create and manage instances of the Identity service from any runtime environment.

In the following procedure, we provide the syntax using the Cloud Foundry command-line interface (cf cli) and the Kubernetes command-line tool (kubectl).

Procedure

1. Create the identity instance.

   The following examples

   - cf cli: **`cf create-service identity application <instance_name>`**
   - kubectl:

   ```
   cat <<EOF | kubectl apply -f -
   apiVersion: servicecatalog.k8s.io/v1beta1
   kind: ServiceInstance
   metadata:
     name: {<instance_name>}
     namespace: {<namespace>}
   spec:
     clusterServiceClassExternalName: identity
     clusterServicePlanExternalName: application
   EOF
   ```

2. Bind your service instance to your application.

   - cf cli: **`cf bind-service <my_app_name> <instance_name>`**
   - kubectl:

   ```
   cat <<EOF | kubectl apply -f -
   apiVersion: servicecatalog.kyma-project.io/v1alpha1
   kind: ServiceBindingUsage
   metadata:
    name: {<instance_name>}
    namespace: {NAMESPACE_NAME}
   spec:
    serviceBindingRef:
      name: {<binding_name>}
    usedBy:
      kind: deployment
      name: {<my_app_name>}
    parameters:
      envPrefix:
        name: "PREFIX_"
   EOF
   ```

3. Consume the binding data.

Binding data consumed by a ...	Then ...
Web application	Use the approuter to authenticate the user. Otherwise, authenticate the user in the application code, according to the OIDC specification using information from service binding (URL, client credentials). For more information, see: • @sap/approuter at *npm*.

Binding data consumed by a ...	Then ...
	• Basic Client Implementer's Guide at *OpenID*.
Service consumed by application (principal propagation)	Validate the token validation and evaluate the binding data using client libraries. For more information, see Reference Information for the Identity Service of SAP BTP [page 2921].

Related Information

Using Services in the Kyma Environment

1.11.2.2 Reference Information for the Identity Service of SAP BTP

Properties enable you to customize the configuration of the Identity service.

Service Properties

> → Tip
>
> If you're creating a new tenant via subscription, `Cloud Identity Services` supports only the `cloud_service` configuration parameter for the subscription creation. The supported values are: **`PRODUCTIVE`** and **`TEST`**. If you provide a different parameter or values, the tenant isn't created. For more information about the tenant creation, see Get Your Tenant [page 528].
>
> If you want to customize the configuration of the Identity service, follow the rest of the information in this document.

Provide properties in JSON format.

The syntax of the properties is as follows:

```
{
  "name": "opportunity-management",
  "authorization": {
    "enabled": true,
    "value_help_url": "https://
myapp_namespace.cert.cfapps.eu10.hana.ondemand.com/odata/v4/ValueHelpService/"
  },
  "oauth2-configuration": {
    "redirect-uris": [

      "refresh-usage-after-renewal" : "off"
    }
  },
  "consumed-services": [
    {
      "service-instance-name": "app_log"
    }
  ],
  "display-name": "Opportunity Management",
  "subject-name-identifier": {
    "attribute": "userUuid",
    "fallback-attribute": "uid"
  },
  "provided-apis": [
    {
      "name": "write-access",
      "description": "grants access to write APIs"
    }
  ]
}
```

Properties for the Creation of an Instance of the Identity Service

Property	Description
`name`	Sets the technical name of the application. The admin console shows this name below the display name in the list of applications and as the name of the *OpenID Connect Configuration*. **⚠ Restriction** The name must be unique in your tenant. By default, the Cloud Identity Services service uses the instance ID generated by the `create-instance` command.

Property	Description
`authorization`	Integrates the SAP Cloud Identity Services - Authorization Management service, enabling instance-based authorizations for your application. For more information about developing applications with Authorization Management, see Developing Authorizations [page 2876]. The `enabled` property is false by default. Set this value to true to create an instance of the service for your SAP Cloud Identity Services tenant. The `value_help_url` property is an absolute URL that points to an OData service of your application. The OData service serves values for attributes defined in the DCL schema of your application. Limits: • The format must be `https://host/path` No fragments (#) allowed HTTPS only
`redirect-uris`	An array of up to 20 redirect URIs that are explicitly allowed for the authorization code flow. **⚠ Restriction** Redirect URIs are required for the authorization code flow to redirect back to your application. This property is empty by default. For more information, see OpenID Connect (OIDC) Application Configurations [page 2747].
`post-logout-redirect-uris`	An array of up to 20 redirect URIs, where users can be forwarded after logout. This property is empty by default. For more information, see Call Identity Authentication End Session Endpoint [page 2740] and OpenID Connect (OIDC) Application Configurations [page 2747].

Property	Description
`front-channel-logout-uris`	An array of up to 20 logout URIs, which are called in a logout flow. This property is empty by default. > **Note** > You can't combine front-channel and back-channel logout URIs in the same configuration. For more information, see OpenID Connect (OIDC) Application Configurations [page 2747].
`back-channel-logout-uris`	An array of up to 20 logout URIs, which are called in a logout flow. This property is empty by default. > **Note** > You can't combine front-channel and back-channel logout URIs in the same configuration. For more information, see OpenID Connect (OIDC) Application Configurations [page 2747].
`public-client`	Set to `true` to enable OAuth flows with public clients. Use public clients in environments where it's difficult to protect client credentials, such as mobile and desktop applications or client-side parts of web applications. This property is `false` by default. For more information, see: - Configure OpenID Connect (OIDC) Application for Authorization Code Flow [page 2642] - Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650]
`grant-types`	An array of allowed grant types. By default, the following grant types are allowed: `client_credentials`, `password`, `authorization_code`, `refresh_token`, and `urn:ietf:params:oauth:grant-type:token-exchange`. The following grant types can be added: `implicit`, `urn:ietf:params:oauth:grant-type:jwt-bearer`, and `authorization_code_pkce_s256`.

Property	Description
`token-policy`	Defines the token policy for the application as determined by the optional properties `token-validity`, `refresh-validity`, and `refresh-parallel`. The admin console also supports the configuration of token policies. For more information, see Token Policy Configuration for Applications [page 2752].
`token-validity`	Sets the lifetime in seconds of tokens issued by the service. The value can range from 60 to 43,200, in other words, from 1 minute to 12 hours. The default value is 3600 seconds, which translates to 1 hour. **Note** The tenant-level Global Session Timeout is an upper bound on the effective token lifetime. If the configured `token-validity` exceeds the remaining session duration, the issued access token is valid only for the time left in the session.
`refresh-validity`	Sets the refresh lifetime of tokens issued by the service. During the refresh lifetime of a token, the service can reissue the token for a user. The value can range from 3600 to 15552000, in other words, from 1 hour to 180 days. Setting the value to 0 disables the refreshing of tokens. The default value is 43200 seconds, which translates to 12 hours. **Note** The tenant-level Global Session Timeout is an upper bound on refresh token validity. Refresh tokens cannot be issued or renewed beyond the remaining session lifetime. Exchanging a refresh token does not extend the session. The resulting token's validity is limited to the time remaining when the exchange occurs.
`refresh-parallel`	Determines the number of tokens that can be issued for the same session in parallel. Imagine you're logged on to the application through a web interface and a command-line interface in parallel. Then you want this property to be set to 2. The value can range from 1 to 10. The default value is 1.

Property	Description
`refresh-usage-after-renewal`	Defines the validity of the old refresh token after requesting a new one through the refresh token grant type. The attribute supports the following values: • `off` - The new refresh token immediately invalidates the old one. • `online` - The new refresh token is created and the old one is still active for 5 minutes. • `mobile` - The new and old refresh tokens are valid during the configured refresh token life time.
`access-token-format`	Defines the format of access tokens. • `default` - The access token format is dependent on the grant type. For more information, see Token Policy Configuration for Applications [page 2752]. • `jwt` - The access token format is JWT. • `opaque` - The access token format is opaque.
`consumed-services`	Use this array to enable the application to consume the APIs of reuse services. Name the reuse services consumed by the application you're protecting. The system adds the client IDs of the reuse services to the audience claim of the identity token. You can name up to 400 services. **Note** If the token is retrieved based on a public flow (`public-client` is true) without client authentication, Cloud Identity Services doesn't add the client IDs of the dependent services to the audience claim. This property is empty by default.

Property	Description
`xsuaa-cross-consumption`	Set to `true` to add the client ID of the Cloud Identity Services application created by the SAP Authorization and Trust Management service (XSUAA) to the audience claim. Setting `xsuaa-cross-consumption` enables cross-consumption of SAP Authorization and Trust Management service. **Note** If the token is retrieved based on a public flow (`public-client` is true) without client authentication, Cloud Identity Services doesn't add the client IDs of the dependent services to the audience claim. The default value is `false`.
`display-name`	Sets the name of the application that you create with the Cloud Identity Services service. Enter a maximum of 99 characters. **→ Recommendation** Provide a display name, which helps the person who administrates the Cloud Identity Services service to understand the purpose of the application. By default, the Cloud Identity Services service uses the name of the instance that you provide in the `create-instance` command.
`subject-name-identifier`	Sets the value to use to fill the subject claim in tokens issued by the service. The `attribute` attribute identifies the user attribute used to fill the subject claim. The attribute supports the following values: • `userUuid` • `uid` • `mail` • `displayName` • `loginName` • `personnelNumber` For more information about attributes for the subject name identifier, see Configure the Subject Name Identifier Sent to the Application [page 1988].

Property	Description
`provided-apis`	An array of API names (`name`) and descriptions (`description`) which this application makes available for other applications to consume. **⚠ Caution** The API name must match exactly what is expected by consumer applications. The name must be unique within all APIs provided by the same provider application. Consumer applications use this name to determine if their application has the rights to access the provider application. The name can be any URN-compliant string of up to 50 characters. You can define a maximum of 50 APIs. For more information about URNs, see RFC 8141 . For more information, see Consuming APIs from Other Applications [page 2889].

Binding Properties

Provide binding properties in JSON format. If you provide no properties, the binding uses the `SECRET` credential type. The syntax of the properties is as follows:

```
{"credential-type": "SECRET"}
```

Or:

```
{
    "credential-type": "X509_GENERATED",
    "key-length": 2048,
    "validity": 30,
    "validity-type": "DAYS",
    "app-identifier":"myApplication"
}
```

Or:

```
{
    "credential-type": "X509_PROVIDED",
    "certificate": "-----BEGIN CERTIFICATE-----\nMIID6zC…\n-----END
CERTIFICATE-----"
}
```

Or:

```
{"credential-type": "NONE"}
```

> ⚠ Restriction
>
> You can bind a maximum of 1000 applications to a single service instance.
>
> You can have a maximum of 20 different certificate subject DNs.

Credential Types for the Binding of an Instance of the Identity Service

Credential Type	Credential Properties	Description
SECRET		Generates a client secret. If no properties are provided, SECRET is the default type.
X509_GENERATED		Generates an X.509 certificate and private key.
	`key-length`	Specifies the byte length of the generated private key. The default length is `2048` bytes. You can also choose `4096` bytes.
	`validity`	Specifies the number of time units for `validity-type`. The default value is `30`. Together with the `validity-type` the range of validity runs from `1 DAYS` to `30 DAYS`.
	`validity-type`	Specifies the time unit for `validity`. Supported values are DAYS. The default value is DAYS.
	`app-identifier`	Enables you to generate a certificate with stable subject. The identifier eases the rotation of the certificates for your microservice while keeping the subject stable. The maximum length is 20 characters.

Credential Type	Credential Properties	Description
`X509_PROVIDED`		Creates a binding using a certificate that you provide from a trusted certificate authority (Certification Authority). This certificate can be used to request tokens. **⚠ Restriction** Don't forget the new lines (`\n`) after `-----BEGIN CERTIFICATE-----` and before `-----END CERTIFICATE-----`. See the previous example. The certificate you provide must be unique in the Cloud Identity Services tenant.
`NONE`		No credentials are added to the binding. Used for public clients. For more information, see Configure the Client to Call Identity Authentication Authorize Endpoint for Authorization Code Flow with PKCE [page 2650].

Binding Information

The service key or binding provides the following information.

- Client ID
- Secrets
  Secrets provided depend on how the service was configured.
  - By default the service generates a client secret.
  - If you had the service generate an X.509 certificate, the binding includes the key and the certificate.
    If you provided the service with your own X.509 certificate, the binding includes the certificate.
  - For public clients, you can suppress the creation of a secret.
- Cloud Identity Services domains
- Cloud Identity Services URL

The following examples show the information stored in the binding:

Binding with client ID and client secret:

```
{
  "clientid": "1aa234ca-faed-4fb2-966e-7c86262ba93c",
```

```
  "clientsecret": "<secret>",
  …
  "domains": ["accounts.ondemand.com", "accounts.cloud.sap"],
  "url": "https://caev6ngwk.accounts.ondemand.com"
}
```

Binding with generated X.509 certificate:

```
{
  "clientid": "1aa234ca-faed-4fb2-966e-7c86262ba93c",
  "key": "<content>",
  "certificate": "<content>",
  …
  "domains": ["accounts.ondemand.com", "accounts.cloud.sap"],
  "url": "https://caev6ngwk.accounts.ondemand.com"
}
```

Binding with provided X.509 certificate:

```
{
  "clientid": "1aa234ca-faed-4fb2-966e-7c86262ba93c",
  "certificate": "<content>",
  …
  "domains": ["accounts.ondemand.com", "accounts.cloud.sap"],
  "url": "https://caev6ngwk.accounts.ondemand.com"
}
```

Binding with no credentials:

```
{
  "clientid": "1aa234ca-faed-4fb2-966e-7c86262ba93c",
  "credential-type": "NONE",
  …
  "domains": ["accounts.ondemand.com", "accounts.cloud.sap"],
  "url": "https://caev6ngwk.accounts.ondemand.com"
}
```

Code Flows

For information about how the Cloud Identity Services service supports code flows, see Configuring OpenID Connect (OIDC) [page 2636].

Token Validation

To validate tokens, we provide client libraries to support the authentication of tokens.

- For Java, see SAP BTP Java Security Client Library on *GitHub*. The Java library supports authentication of tokens from version 2.8.0.
- For node.js, see @sap/xssec: XS Advanced Container Security API for node.js on *npm*.

Token Attributes

The administrator of the Cloud Identity Services service determines what attributes are available in tokens. For more information, see Configuring User Attributes from the Identity Directory [page 1973].

1.11.3 Integrating the Service with SAP Web IDE Full-Stack

You can use Identity Authentication as identity provider for SAP Web IDE Full-Stack.

Prerequisites

- You have a subaccount for SAP BTP.
  For more information, see Getting a Paid Enterprise Global Account.
- You have an Identity Authentication tenant. For more information about how to get Identity Authentication, see SAP BTP Pricing and Packaging Options, or contact your SAP sales representative.
- You have registered the Identity Authentication as a trusted identity provider for your SAP BTP account. See Identity Authentication Tenant as an Application Identity Provider.
- You have set the trust with SAP BTP. For more details, see Configure Trust [page 1941].
- You have switched off the *Reload Parent Page* option for SAP Web IDE Full-Stack in the administration console for SAP Cloud Identity Services. For more information, see Enable or Disable Reload Parent Page Option [page 2044].
- You have added your SAP Web IDE Full-Stack host to the list of the trusted domains in the administration console for SAP Cloud Identity Services. For more information, see Configure Trusted Domains [page 2173].
- You have checked the **User ID** of the users that will be able to access SAP Web IDE Full-Stack. The **User ID** is a six-digit number preceded by the letter **P**. For more information about how to check the **User ID**, see List and Edit User Details [page 2361].

Context

> **Note**
>
> The content in this section is only relevant for SAP BTP, Neo environment.

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

The integration between SAP Web IDE Full-Stack and Identity Authentication enables users to access SAP Web IDE Full-Stack with their Identity Authentication credentials.

SAP Web IDE Full-Stack access is protected by permissions. To grant a user the permission to access a protected resource, you can assign one of the predefined roles to such a permission. The following predefined roles are available:

- `DiDeveloper` - To develop with SAP Web IDE Full-Stack, the DiDeveloper role needs to be assigned.
- `DiAdministrator` - To be able to manage user data, a user has to be assigned to the DiAdministrator role.
- `DiScpGitAdministrator`- To be able to manage Git repositories, a user has to be assigned to the DiScpGitAdministrator role.

> → Remember
>
> You should use the `DiDeveloper` or `DiAdministrator` role to enable users to access SAP Web IDE Full-Stack with their Identity Authentication credentials. For more information, see Assign DiDeveloper or DiAdministrator Roles [page 2933].

Hybrid Scenario: SAP Identity Management [page 2961]
Blogs [page 2964]

1.11.3.1 Assign `DiDeveloper` or `DiAdministrator` Roles

Context

If you want to use the `DiDeveloper` or `DiAdministrator` role together with Identity Authentication as an identity provider, complete the following steps:

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. In the navigation area, choose *Services* > *SAP Web IDE Full-Stack tile*.

   > ⓘ Note
   >
   > If not enabled, choose *Enable*.

3. Choose *Configure Service* under *Take Action*.
4. On the *Configure Service - Roles* tab, under *New Role*, select either `DiDeveloper` or `DiAdministrator` from the list of predefined roles.
5. Choose *Assign* from the *Individual User* section.
6. Enter the **User ID** (the **P number)** of the user in question and choose *Assign*.

   > ⓘ Note
   >
   > For more information how to check the *User ID*, see List and Edit User Details [page 2361]. The *User ID* is a six-digit number preceded by the letter **P**.

Results

The assigned users can log on to SAP Web IDE Full-Stack with their credentials for Identity Authentication (email and password).

1.11.3.2 Show User's Name on SAP Web IDE Full-Stack Home Page

Context

When you use Identity Authentication as a trusted identity provider for SAP Web IDE Full-Stack you can configure the application to display the first name of the user that is logged on in the **menu bar** and the welcome screen.

For this scenario, you have to configure the user attribute `First Name` in Identity Authentication to be sent to SAP Web IDE Full-Stack in the assertion attribute. You also have to configure the First Name user attribute mapping for Identity Authentication in the SAP BTP cockpit.

Configure `First Name` User Attribute in Identity Authentication

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose your SAP Web IDE Full-Stack application from the list.
4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Attributes*.
6. Configure the `First Name` attribute.
7. Save your configuration.

   If the operation is successful, you receive the message `Attributes updated`.

Configure Mapping in SAP BTP

Procedure

1. In your Web browser, open the SAP BTP cockpit using the following URLs:
   - Europe: https://account.hana.ondemand.com/cockpit
   - United States: https://account.us1.hana.ondemand.com/cockpit
   - Australia: https://account.ap1.hana.ondemand.com/cockpit
2. Select the customer account and choose *Trust* in the navigation bar.
3. Choose the *Application Identity Provider* subtab, and then choose the identity provider that SAP Web IDE Full-Stack uses for authentication.
4. Choose *Attributes* > *Add Assertion-Based Attribute* > .
5. Enter the fields as follows:

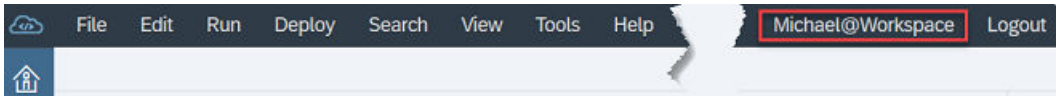
Assertion Attribute	Principal Attribute
first_name	firstname

> **Note**
>
> The *Assertion Attribute* field is for the attribute that comes from the SAML Assertion.
>
> The *Principal Attribute* field is the user attribute that the users will have at SAP BTP.

6. Save your changes.

Results

Once the user has been successfully authenticated to SAP Web IDE Full-Stack, his or her name will appear in *Menu bar* on the right.



1.11.4 Integrating the Service with SAP Document Center

You can use Identity Authentication as identity provider for SAP Document Center.

Prerequisites

- You have a subaccount for SAP BTP.
  For more information, see Getting a Paid Enterprise Global Account.
- You have an Identity Authentication tenant. For more information about how to get Identity Authentication, see SAP BTP Pricing and Packaging Options, or contact your SAP sales representative.
- You have registered the Identity Authentication as a trusted identity provider for your SAP BTP account. See Identity Authentication Tenant as an Application Identity Provider.
- You have set the trust with SAP BTP. For more details, see Configure Trust [page 1941].
- You have added your SAP Document Center host to the list of the trusted domains in the administration console for SAP Cloud Identity Services. For more information, see Configure Trusted Domains [page 2173].
  You have checked the **User ID** of the users that can access SAP Document Center. The **User ID** is a six-digit number preceded by the letter **P**. For more information about how to check the **User ID**, see List and Edit User Details [page 2361].
- *Optional (for the group assignment):* You have created a user group in Identity Authentication and assigned that group to the users you want to give authorizations to access SAP Document Center.

Context

> **Note**
>
> The content in this section is only relevant for SAP BTP, Neo environment.

> **Note**
>
> The content in this section is not relevant for China (Shanghai) region.

The integration between SAP Document Center and Identity Authentication enables users to access SAP Document Center with their Identity Authentication credentials. Identity Authentication users must be assigned to the specific *Web* roles for SAP Document Center. The specific roles contain the access authorizations for the user interfaces (UIs). For more information about the specific *Web* roles of SAP Document Center see, Assigning Users to Roles

The configuration steps are done in the administration console for SAP Cloud Identity Services and in the cockpit of SAP BTP.

Task overview: Integrating the Service [page 2910]

Hybrid Scenario: SAP Identity Management [page 2961]
Blogs [page 2964]

1.11.4.1 Assign Identity Authentication Users to Roles

Context

You can use Java EE roles to define access to SAP Document Center. You can assign the respective roles for SAP Document Center to users or to groups of users of Identity Authentication. For more information about the specific web roles for SAP Document Center, see Assigning Users to Roles.

You have three options to define access:

- Assign Users to Roles
- Assign Groups to Roles
- Assign Default Groups

Assign Users to Roles

Context

Assign the respective roles for SAP Document Center to individual users of Identity Authentication.

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. In the navigation area go to *Services* > *SAP Document Center*.

   > → Tip
   >
   > Choose *Enable* if the service is not enabled for this account.
3. Under *Service Configuration* choose *Assign Roles & Set Destinations*.
4. Under *Roles* select the role you want to manage assignments for. For more information about the specific web roles for SAP Document Center, see Assigning Users to Roles.
5. Choose *Assign* for the *Individual Users* section.
6. Enter the **User ID** (the **P number)** of the user in question and choose *Assign*.

   > ⓘ Note
   >
   > For more information how to check the *User ID*, see List and Edit User Details [page 2361]. The *User ID* is a six-digit number preceded by the letter **P**.

Results

The assigned user can log on to SAP Document Center with their credentials for Identity Authentication.

Assign Groups to Roles

Context

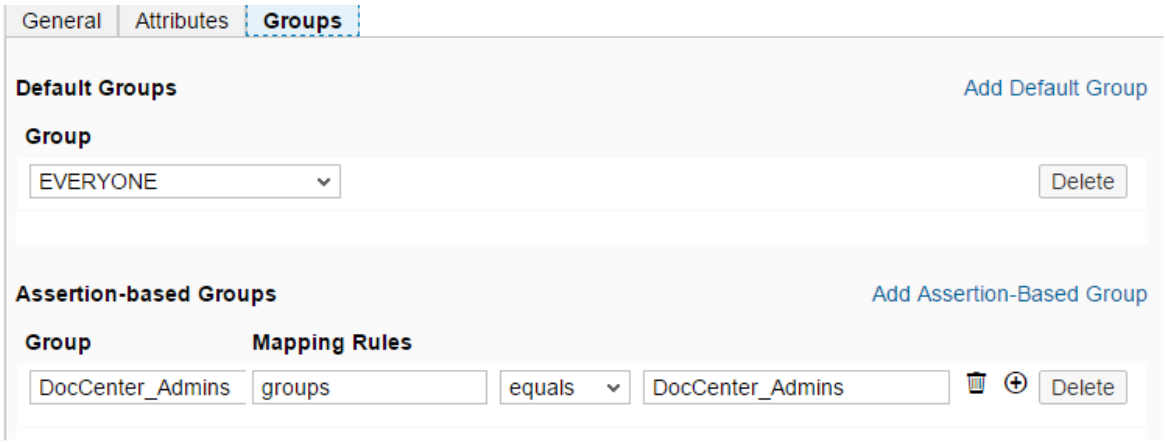
Assign the respective roles for SAP Document Center to collections of users of Identity Authentication instead of individual users. Groups allow you to easily manage the role assignments.

Assertion-based groups are groups determined by values of attributes in the SAML 2.0 assertion.

Procedure

1. Assign a group to users of Identity Authentication. For more information, see Assign Groups to a User [page 2409].

   For example, you can have a group *EVERYONE* for all the users of Identity Authentication, and a group *DocCenter_Admins* just for the administrators. In this case, you should assign the group EVERYONE to all the users of Identity Authentication, and just the administrators to the *DocCenter_Admins* group.
2. Configure the `groups` attribute that is sent to SAP Document Center in the SAML 2.0 assertion. For more information, see Configuring User Attributes from the Identity Directory [page 1973]
3. In the cockpit of SAP BTP define the assertion based groups for the group-to-role mapping in the cockpit. For more information, see 4. (If Using an Identity Provider) Define the Group-to-Role Mapping.



Results

All users that are members of the group can access SAP Document Center.

1.11.4.2 Configure User Attributes Mapping

You have to specify how the user attributes are sent to SAP BTP in the assertion, and define their mapping.

1. Configure User Attributes in Identity Authentication

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.

2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose your SAP BTP application from the list.
4. Choose the *Trust* tab.
5. Under *SINGLE SIGN-ON*, choose *Attributes*.
6. Configure the attributes.
7. Save your configuration.

   If the operation is successful, you receive the message `Attributes updated`.

Related Information

Configuring User Attributes from the Identity Directory [page 1973]

2. Configure Mapping in SAP BTP

Procedure

1. Sign in SAP BTP cockpit with the cockpit administrator role. For more information, see Subaccounts.
2. Select the subaccount and choose *Trust* in the navigation bar.
3. Choose the *Application Identity Provider* > *the identity provider that the platform uses for authentication*.
4. Choose *Attributes* > *Add Assertion-Based Attribute*.
5. Enter the fields as follows:

Assertion Attribute	Principal Attribute
*	*

> **Note**
>
> This specifies that all assertion attributes will be mapped to the corresponding principal attributes without a change
>
> The *Assertion Attribute* field is for the attribute that comes from the assertion.
>
> The *Principal Attribute* field is the user attribute that the users will have at SAP BTP.

6. Save your changes.

1.11.6 Integrating the Service with SAP S/4HANA Cloud Public Edition, SAP Integrated Business Planning and SAP Analytics Cloud

This integration document aims to provide information about single sign-on (SSO) options for SAP S/4HANA Cloud Public Edition or SAP Integrated Business Planning and SAP Analytics Cloud, that use Identity Authentication as an authenticating or proxy identity provider.

SAP Analytics Cloud, is integreted in SAP S/4HANA Cloud Public Edition or in SAP Integrated Business Planning, or it can be part of SAP Datasphere, that is integrated with SAP S/4HANA Cloud Public Edition as of SAP S/4HANA Cloud Public Edition 2208.

- Use Identity Authentication as Authenticating IdP [page 2942]

1.11.6.1 Use Identity Authentication as Authenticating IdP

In this scenario, to log on to an application, users provide their credentials to Identity Authentication, and Identity Authentication asserts their identity to the application.

Every SAP S/4HANA system or SAP Analytics Cloud embedded come with an Identity Authentication as a trusted identity provider. You've received a provisioning email with initial access information for the Identity Authentication tenant.

> → Tip
>
> If you need your users in the tenant of Identity Authentication, you can import them, or create them via the administration console or the Identity Directory API.

The tables below show the pre-configured settings for your system that you have in the Identity Authentication administration console.

> ⓘ Note
>
> The tenant URL has the following pattern:
>
> `https://<tenant ID>.accounts.ondemand.com/admin`
>
> *Tenant ID* is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*. For more information about your tenants, see View Assigned Tenants and Administrators [page 525].
>
> If you have a configured custom domain, the URL has the following pattern: `<your custom domain>/admin`.

ABAP tenants provisioned before SAP S/4HANA Cloud Public Edition 2208

System	Trust-Related Setting	Value
S/4HANA Cloud Public Edition or Integrated Business Planning	`Subject Name Identifier`	**`Login Name`** **Note** For successful authentication, the user name of the business user in S/4HANA Cloud Public Edition or Integrated Business Planning must be identical to the login name.
	`Default Name ID Format`	**`Unspecified`**
	`Apply Function to Subject Name Identifier`	**`None`** (ABAP does implicit uppercase conversion)
	`Conditional Authentication`	Identity Authentication
SAP Analytics Cloud, embedded edition	`Subject Name Identifier`	**`Login Name`**
	`Default Name ID Format`	**`Unspecified`**
	`Apply Function to Subject Name Identifier`	**`Uppercase`**
	`Conditional Authentication`	Identity Authentication

ABAP tenants provisioned from SAP S/4HANA Cloud Public Edition 2208 onwards

Application	Trust-related setting	Value
S/4HANA Cloud Public Edition or SAP Integrated Business Planning	`Subject Name Identifier`	**`Email`** **Note** For successful authentication, the email address of the business user in S/4HANA Cloud Public Edition or Integrated Business Planning must be identical to the email.
	`Default Name ID Format`	**`Email`**
	`Apply Function to Subject Name Identifier`	**`None`** (email addresses are compared case-insensitively)
	`Conditional Authentication`	**`Identity Authentication`**
SAP Analytics Cloud, embedded edition	`Subject Name Identifier`	**`Email`**
	`Default Name ID Format`	**`Unspecified`**
	`Apply Function to Subject Name Identifier`	**`Lowercase`**
	`Conditional Authentication`	**`Identity Authentication`**

Application	Trust-related setting	Value
SAP Datasphere	`Subject Name Identifier`	**`Email`**
	`Default Name ID Format`	**`Email`**
	`Apply Function to Subject Name Identifier`	**`None`** (email addresses are compared case-insensitively)
	`Conditional Authentication`	**`Identity Authentication`**

> **Note**
>
> The same identifying attribute (login name or email address) is used for both ABAP and SAP Analytics Cloud. User records must be created in ABAP and are then automatically replicated to SAP Analytics Cloud:

- Replication from SAP S/4HANA Cloud Public Edition to SAP Analytics Cloud happens via a pre-integrated Identity Provisioning tenant (communication scenario *SAP_COM_0193*).
- Replication from SAP Integrated Business Planning to SAP Analytics Cloud happens via the SAP-managed communication scenario *SAP_COM_1187*.

1.11.6.2 Use Your Own Corporate IdP for Authentication

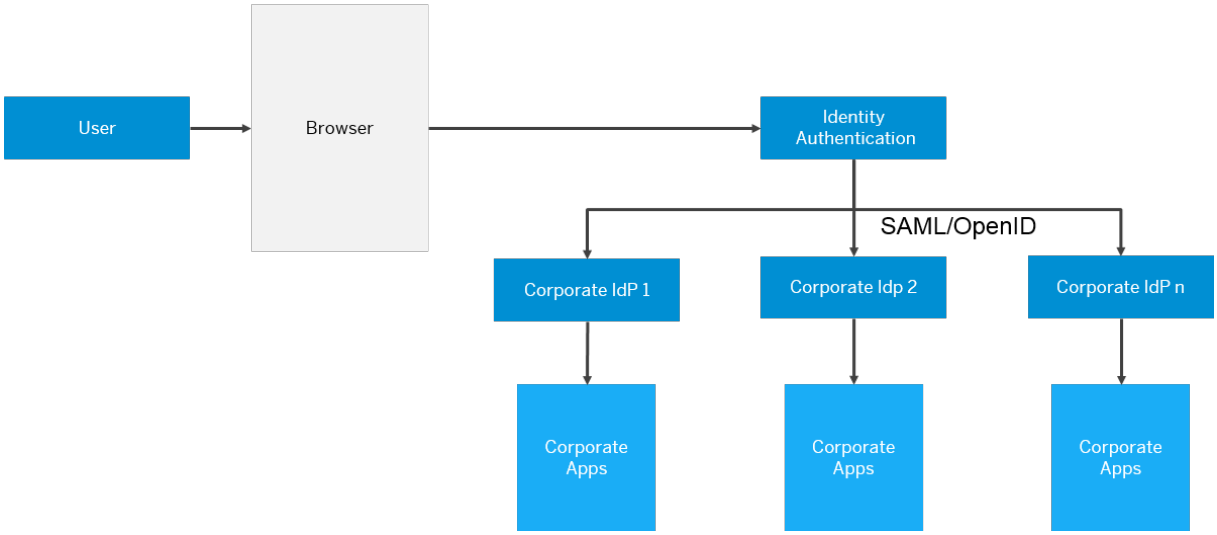
This document is intended to help you configure trust with a corporate identity provider. In this scenario Identity Authentication acts as a proxy to delegate the authentication to the corporate identity provider.

Context

In this scenario Identity Authentication acts as a proxy to delegate the authentication to the corporate identity provider. The requests for authentication sent by a service provider/relying party will be forwarded to the corporate identity provider.

Identity Authentication can use a SAML 2.0 or OpenID Connect identity provider as an external authenticating authority. The choice of one or the other protocol depends on your scenario and needs.

As an identity provider proxy, Identity Authentication will act as an identity provider to the service provider/ relying party, and as a service provider/relying party to the corporate identity provider. Once a user is authenticated at the corporate identity provider, successive authentication requests from service providers/ relying parties, which use the same corporate identity provider will not be forwarded to it as long as the session at Identity Authentication is active. Identity Authentication will issue assertions or JSON Web Tokens (JWTs) based on the user data received during the first authentication.



→ Remember

For the embeded version of SAP Analyics Cloud, the *Forward All SSO Requests to Corporate IdP* option must be disabled. Identity Authentication forwards the SSO request to the corporate identity provider only during the first sign in flow to SAP S/4HANA Cloud Public Edition, but not during the subsequent sign in flow to SAP Analytics Cloud.

To use Identity Authentication as a proxy to delegate authentication to an external corporate identity provider choose your scenario and follow the procedures below:

- Configure Trust with SAML 2.0 Corporate Identity Provider [page 2946]
- Configure Trust with OpenID Connect Corporate Identity Provider [page 2949]
- Configure Identity Federation [page 2949]

1.11.6.2.1 Configure Trust with SAML 2.0 Corporate Identity Provider

This document is intended to help you configure trust with a SAML 2.0 corporate identity provider.

Context

> ⓘ Note
>
> If an application requires force authentication (ForceAuthn="true"), users have to authenticate themselves against the corporate identity provider each time they access the application even if single sign-on (SSO) is enabled.

To configure trust with the SAML 2.0 corporate identity provider, follow the procedures below:

1. Configure Trust on the Corporate Identity Provider Side

Set up trust with Identity Authentication as a service provider.

Prerequisites

You have the SAML 2.0 metadata of Identity Authentication. For more information how to download the metadata, see Tenant SAML 2.0 Configurations [page 2103].

Procedure

1. Register Identity Authentication as a service provider at the corporate identity provider.

   > → Remember
   >
   > If you want to use IdP-initiated single sign-on (SSO) from your corporate identity provider, you have to add the parameter `sp=<sp_name>` to the assertion consumer service (ACS) endpoint configured on your corporate identity provider side for Identity Authentication.
   >
   > > ✤ Example
   > >
   > > https://<the current ACS endpoint URL>?sp=<sp_name>>
   > >
   > > `sp` is the name of the SAML 2 service provider for which SSO is performed.

> To see how to download the SAML 2.0 metadata of Identity Authentication read Tenant SAML 2.0 Configurations [page 2103].

2. **Optional:** Download the corporate identity provider SAML 2.0 metadata.

   You need the corporate SAML 2.0 metadata for the setup of the trust on Identity Authentication. Optionally, you can make the configurations manually.

2. Configure Trust on Identity Authentication Side

Set up trust with your corporate identity provider in the administration console for SAP Cloud Identity Services.

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have registered Identity Authentication as service provider at the corporate identity provider.
- You have the corporate identity provider SAML 2.0 metadata.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure.

   > → Tip
   >
   > If you need to change the protocol, see Choose Identity Provider Type [page 2602].

4. Under *SAML 2.0*, choose *SAML 2.0 Configuration*.
5. Upload the corporate identity provider metadata XML file or manually enter the communication settings negotiated between Identity Authentication and the identity provider.

   > ⓘ Note
   >
   > Use a file with an extension `.xml`.

   When the identity provider metadata is uploaded, the fields are populated automatically with the parsed data from the XML file. The minimum configuration is to complete the *Name* field, add at least one single sign-on endpoint, and provide a signing certificate.

   You can add up to two signing certificates. Both signing certificates are accepted according to the certificate validity.

Field	Description
Metadata File	The metadata XML file of the identity provider.
Name	The entity ID of the identity provider.
Single Sign-On Endpoint URL	The URL of the identity provider single sign-on endpoint that receives authentication requests.
Single Logout Endpoint URL	The URL of the identity provider's single logout endpoint that receives logout messages.
Binding	The SAML-specified HTTP binding used by the identity provider showing how the various SAML protocol messages can be carried over underlying transport protocols.
Signing Certificate	A base64-encoded certificate used by the service provider to sign digitally SAML protocol messages sent to Identity Authentication. Use the *Add* button to add a second signing certificate. **Note** If you have two certificates, you can choose a default one, to mark your primary certificate.

6. **Optional:** Choose the digest algorithm for signing outgoing messages from the dropdown list in the *Algorithm* section. You have the following options:
   - *SHA-1*
   - *SHA-256* - the default option

     → Remember

     The algorithm must be *SHA-256* if the Identity provider type is set at *Microsoft ADFS / Entra ID*.
   - *SHA-512*
7. **Optional:** Enable or disable the *Include scoping* attribute to include or exclude the Scoping element in the SAML 2.0 request.

   → Remember

   The default setting for the *Include scoping* is enabled. The Scoping element sent in the SAML 2.0 request is 1.

   If the identity provider type is set at *Microsoft ADFS / Entra ID* the default setting for the *Include scoping* is disabled and the Scoping element is not sent in the SAML 2.0 request.
8. Save your selection.

   Once the identity provider has been updated, the system displays the message `Identity provider <name of identity provider> updated`.

Next Steps

- Select the configured identity provider as the authenticating identity provider for the application. For more information, see Choose Default Identity Provider for an Application [page 2067].
- (Optional) Configure the Name ID Format Attribute Sent to the SAML 2.0 Corporate IdP [page 2577]
- Configure Identity Federation [page 2949]

1.11.6.2.2 Configure Trust with OpenID Connect Corporate Identity Provider

This document is intended to help you configure trust with a corporate identity provider.

Context

In this scenario Identity Authentication acts as a proxy to delegate the authentication to the corporate identity provider. To use Identity Authentication as a proxy to delegate authentication to an OpenID Connect corporate identity provider you have to configure trust with that corporate identity provider. For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].

Next Steps

Configure Identity Federation [page 2949]

1.11.6.2.3 Configure Identity Federation

Prerequisites

- You are assigned the *Manage Corporate Identity Providers* role. For more information about how to assign administrator roles, see Edit Administrator Authorizations [page 2309].
- You have configured Identity Authentication to use the OpenID Connect corporate identity provider as an external authenticating authority. For more information, see Configure Trust with OpenID Connect Corporate Identity Provider [page 2579].
- You have selected the configured identity provider as the authenticating identity provider for your application. For more information, see Choose Default Identity Provider for an Application [page 2067].
- You have imported the users, authenticated by the corporate identity provider, in Identity Authentication. For more information about how to import users, see Import or Update Users for a Specific Application [page 2348].

Context

By default, *Use Identity Authentication user store* is disabled.

In scenarios when the application is using for authentication a corporate identity provider, and the *Use Identity Authentication user store* option is disabled, the user attributes, the name ID attribute, and the default attributes configurations in the administration console for SAP Cloud Identity Services are not relevant. In such scenarios, Identity Authentication sends to the application the same attributes it has received from the corporate identity provider (no change in the Subject Name Identifier or its format - Unspecified or Email). As a consequence, the same format is used not only for the ABAP and SAP Analytics Cloud tenants but also for all other SAP applications connected to the same Identity Authentication tenant, which may lead to contradictions if some applications require a different format.

When *Use Identity Authentication user store* option is enabled, the application checks if the users authenticated by the corporate identity provider exist in the Identity Authentication user store. For users that exist in Identity Authentication, data from Identity Authentication user store is taken and the subject name identifier, assertion and default attributes according to the application configuration are sent. For users with no profile in Identity Authentication, the application receives the nameID attribute from the corporate IdP assertion, and the attributes according to the application configuration.

When *Use Identity Authentication user store* is enabled, it is possible to configure different name ID Formats per application. The values for all necessary formats must be contained in the assertion issued by the corporate identity provider:

- as Subject Name Identifier in the SAML 2.0 assertion
- or as a SAML Assertion Attribute.
- or as a claim in an OpenID Connect token

Example

SAML 2.0 Scenario

The ABAP and SAP Analytics Cloud tenants require email address (in our example *dona.moore@test.com*) for logon, and another application requires the login name. If the corporate identity provider issues an assertion containing the login name as Subject Name Identifier and an Attribute Statement containing an email address, the SAML assertion XML document would contain:

Sample Code

```
<Subject>
  <NameID Format="urn:oasis:names:tc:SAML:1.1:nameid-
format:unspecified">P012345</NameID>
  ...
</Subject>
...
<AttributeStatement>
  <Attribute Name="mail">
    <AttributeValue xsi:type="xs:string">dona.moore@test.com</
AttributeValue>
  </Attribute>
  ...
</AttributeStatement>
```

Note

In this case, the setting Subject Name Identifier = Login Name is relevant only for Identity Authentication administrators, for whom a user record exists in Identity Authentication. These will be logged on to the other application with the login name from their Identity Authentication user record, which must therefore be the same as in their corporate identity provider user record. For all other users, the Subject Name Identifier asserted by the corporate identity provider (in the example, `P012345`) will be used for logon to the other application.

Example

OpenID Connect Scenario

If the corporate identity provider issues an OpenID Connect token containing the login name as Subject Name Identifier and the email address as an Assertion Attribute. The JSON web token would contain claims like:

Sample Code

```
{"sub": "P012345",
 "mail": "dona.moore@test.com",
 ...}
```

If the ABAP and SAP Analytics Cloud tenants require the email address (in our example *dona.moore@test.com*) for logon, but another application requires the login name, this can be achieved with the following configuration in the administration console for SAP Cloud Identity Services:

Scenario Settings

Application	Trust-Related Setting	Value (SAML 2.0 Scenario)	Value (OpenID Connect Scenario)
ABAP	Subject Name Identifier	*Source*: **Corporate Identity** *Value*: **mail**	*Source*: **Corporate Identity** *Value*: **mail**
	Default Name ID Format	**Email**	**Email**
	Apply Function to Subject Name Identifier	**None**	**None**
	Conditional Authentication	**<your corporate identity provider>**	**<your corporate identity provider>**
SAP Analytics Cloud	Subject Name Identifier	*Source*: **Corporate Identity** *Value*: **mail**	*Source*: **Corporate Identity** *Value*: **mail**
	Default Name ID Format	**Email**	**Email**
	Apply Function to Subject Name Identifier	**None**	**None**

Application	Trust-Related Setting	Value (SAML 2.0 Scenario)	Value (OpenID Connect Scenario)
	`Conditional Authentication`	**`<your corporate identity provider>`**	**`<your corporate identity provider>`**
Other Application	`Subject Name Identifier`	**`Login Name`**	*Source*: **`Corporate Identity`** *Value*: **`sub`**
	`Default Name ID Format`	**`Unspecified`**	**`Unspecified`**
	`Apply Function to Subject Name Identifier`	**`None`**	**`None`**
	`Conditional Authentication`	**`<your corporate identity provider>`**	**`<your corporate identity provider>`**

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Select the corporate identity provider that you want to configure for *Identity Federation*.
    - If you do not have an identity provider in your list, click the *Add* button to create one, and proceed with the configuration.
    - If you have an identity provider in your list, choose the one that you want to configure.
4. Choose *Identity Federation* to configure the options.
5. Use the slider next to *Use Identity Authentication user store* to enable or disable it.

1.11.7 Integrating the Service with Microsoft Entra ID

Identity Authentication is part of the application gallery of Microsoft Entra ID (formerly known as Microsoft Azure Active Directory or Azure AD) under the name Identity Authentication.

This integration aims to provide single sign-on (SSO) between applications using Microsoft Entra ID as authenticating identity provider and applications using Identity Authentication as proxy identity provider.

Prerequisites

- You have a valid Microsoft Entra ID subscription.
- You have a subscription for Identity Authentication. For more information how to get Identity Authentication, see Initial Setup [page 523].

Overview

In this scenario Identity Authentication acts as a proxy identity provider and Microsoft Entra ID as the main authentication authority for the applications. The authentication requests sent to Identity Authentication are redirected to Microsoft Entra ID. User management and authentication is done on Microsoft Entra ID side.

> ⓘ Note
>
> Users who are in the Microsoft Entra ID user store can use the single sign-on (SSO) functionality.
>
> Users who are provisioned to Identity Authentication, but not to Microsoft Entra ID, are not able to log on.

> → Tip
>
> Identity Authentication supports the *Identity Federation* option. This option allows the application to check if the users authenticated by the corporate identity provider exist in the user store of Identity Authentication. In the default setting, the *Identity Federation* option is disabled. If *Identity Federation* is enabled, only the users that are imported in Identity Authentication are able to access the application. For more information about how to enable or disable *Identity Federation* with Identity Authentication, see **Enable Identity Federation with Identity Authentication** in Configure Identity Federation [page 2614].

For this scenario, the configurations are made in Microsoft Entra ID classic portal and in the administration console for SAP Cloud Identity Services.

1. Configure Microsoft Entra ID [page 2954]
   Configure Microsoft Entra ID to integrate with Identity Authentication.
2. Configure Microsoft Entra ID as Corporate Identity Provider at Identity Authentication [page 2955]
   Create and configure Microsoft Entra ID as a corporate identity provider in the administration console for SAP Cloud Identity Services.
3. (Optional) Configure Different Trust Configurations for the Same Identity Authentication Tenant (Microsoft Entra ID Apps) [page 2956]
   Configure issuer name on Identity Authentication and update the name and certificate on Microsoft Entra ID side.

Hybrid Scenario: SAP Identity Management [page 2961]
Blogs [page 2964]

1.11.7.1 Configure Microsoft Entra ID

Configure Microsoft Entra ID to integrate with Identity Authentication.

Prerequisites

You have a valid Microsoft Entra ID subscription.

Context

For the configuration of Microsoft Entra ID see Tutorial: Microsoft Entra single sign-on (SSO) integration with SAP Cloud Identity Services .

> ⓘ Note
>
> For the configuration you need the metadata of your Identity Authentication tenant. For more information about how to get it, see Tenant SAML 2.0 Configurations [page 2103].

> → Tip
>
> Download and save the Microsoft Entra ID Metadata XML file. You will need it for the configuration of Microsoft Entra ID as corporate identity provider at Identity Authentication.

Task overview: Integrating the Service with Microsoft Entra ID [page 2952]

Next task: Configure Microsoft Entra ID as Corporate Identity Provider at Identity Authentication [page 2955]

1.11.7.2 Configure Microsoft Entra ID as Corporate Identity Provider at Identity Authentication

Create and configure Microsoft Entra ID as a corporate identity provider in the administration console for SAP Cloud Identity Services.

Prerequisites

- You have a subscription for Identity Authentication. For more information how to get Identity Authentication, see Initial Setup [page 523].
- You have configured Microsoft Entra ID.

Context

To use Identity Authentication as a proxy, create, and configure Microsoft Entra ID as a corporate identity provider in the administration console for SAP Cloud Identity Services. This corporate identity provider is used as an authenticating authority for the applications.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Identity Providers*, choose the *Corporate Identity Providers* tile.
3. Choose the *Add* button to create an Microsoft Entra ID corporate identity provider.

   > **Note**
   >
   > If you have an Microsoft Entra ID corporate identity provider in your list, choose it, and proceed with its configuration. Type the name of the identity provider in the search field to filter the list items.

4. Under *SAML 2.0*, choose *SAML 2.0 Configuration*.
5. Upload Microsoft Entra ID metadata XML file or configure manually the following fields:

Field	Information
Name	Provide the `entity ID` of the corporate identity provider.
Single Sign-On Endpoint URL	Provide the URL of the identity provider single sign-on endpoint that receives authentication requests. For *Binding*, choose the one that corresponds to respective single sign-on endpoint.

Field	Information
Single Logout Endpoint URL	Provide the URL of the identity provider's single logout endpoint that receives logout messages. For *Binding*, choose the one that corresponds to respective single logout endpoint.
Signing Certificate	Provide the base64-encoded certificate used by the identity provider to digitally sign SAML protocol messages sent to Identity Authentication.

→ Tip

The information for the manual configuration is in the metadata XML file of Microsoft Entra ID.

Next Steps

1. Choose **Microsoft ADFS / Entra ID** as the type for the configured corporate identity provider. For more information, see Choose Identity Provider Type [page 2602].
2. Select the configured identity provider as the authenticating identity provider for the desired application. For more information, see Choose Default Identity Provider for an Application [page 2067].

Task overview: Integrating the Service with Microsoft Entra ID [page 2952]

Previous task: Configure Microsoft Entra ID [page 2954]

Next task: (Optional) Configure Different Trust Configurations for the Same Identity Authentication Tenant (Microsoft Entra ID Apps) [page 2956]

1.11.7.3 (Optional) Configure Different Trust Configurations for the Same Identity Authentication Tenant (Microsoft Entra ID Apps)

Configure issuer name on Identity Authentication and update the name and certificate on Microsoft Entra ID side.

Context

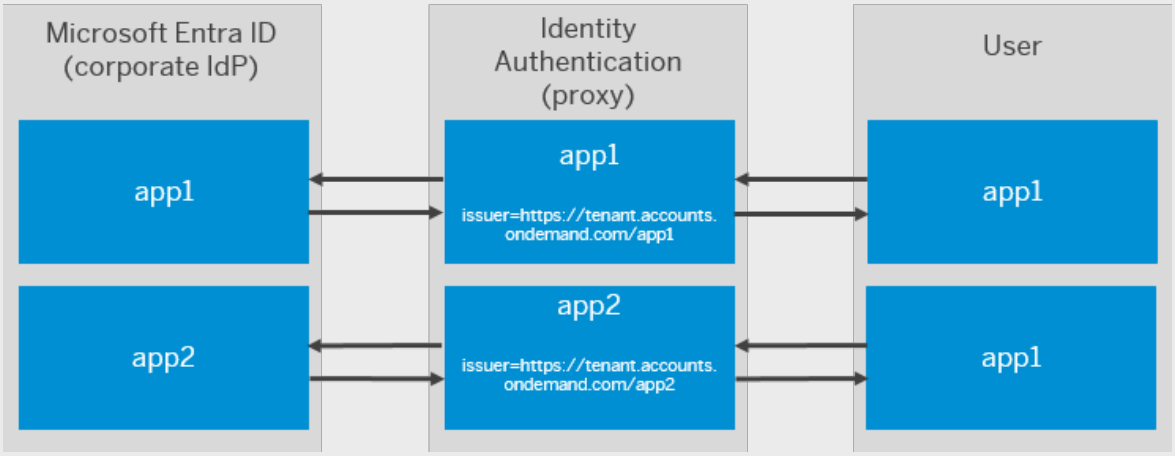
When Identity Authentication acts as a proxy identity provider you can have different trust configurations for the different applications at Microsoft Entra ID side, acting as a corporate identity provider. To do this you should configure Identity Authentication to use a different issuer name when communicating with Microsoft Entra ID, depending on the application for which the authentication is done.

When Identity Authentication issues a SAML2.0 authentication request, logout request or response to Microsoft Entra ID, then it uses the configured issuer name for the corresponding application.

When Identity Authentication verifies the SAML2.0 message coming from Microsoft Entra ID, then the verification is done against the configured issuer for the corresponding application.

The configuration is done both in Identity Authentication and Microsoft Entra ID.

Example



Identity Authentication acts as identity provider proxy and there are two configured applications app1 and app2. App1 is configured with `issuer=https://tenant.accounts.ondemand.com/app1`. App2 is configured with `issuer=https://tenant.accounts.ondemand.com/app2`. Both applications use one and the same corporate identity provider for authentication.

When App1 issues an authentication request to Identity Authentication, then Identity Authentication sends authentication request to Microsoft Entra ID, using `issuer=https://tenant.accounts.ondemand.com/app1`. Microsoft Entra ID authenticates the user and sends authentication response with `audience=https://tenant.accounts.ondemand.com/app1`. Then Identity Authentication sends authentication response to app1.

After that, the same user tries to authenticate to app2 from the same browser session. App2 issues an authentication request to Identity Authentication. Then Identity Authentication again sends authentication request to Microsoft Entra ID, but this time with `issuer=https://tenant.accounts.ondemand.com/app2`. Thus, Microsoft Entra ID can apply the specific authentication mechanisms, configured for `issuer=https://tenant.accounts.ondemand.com/app2` . After the authentication,Microsoft Entra ID issues an authentication response with `audience=https://tenant.accounts.ondemand.com/app2`. Then Identity Authentication sends authentication response to app2.

Task overview: Integrating the Service with Microsoft Entra ID [page 2952]

Previous task: Configure Microsoft Entra ID as Corporate Identity Provider at Identity Authentication [page 2955]

1. Configure Issuer Name at Identity Authentication

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Under *Applications and Resources*, choose the *Applications* tile.
3. Choose the *Trust* tab.
4. Choose the application that you want to edit.
5. Under *Conditional Authentication*, choose *Configure Requests to Corporate Identity Providers*.
6. Under *Configure Issuer Name*, type the issuer suffix, which you want to add to the Identity Authentication default issuer name.

   > ⓘ Note
   >
   > The issuer name can contain Latin letters (A-Z and a-z), numbers, and the dash (-) character. It can be up to 36 characters.

   The issuer name, which will be used when sending SAML2.0 requests to the corporate identity provider appears under the input field. It is in the format `<Identity_Authentication_default_issuer_name>/<issuer_name_suffix_typed_in_the_input_field>` . For example, `https://my-tenant.accounts.ondemand.com/issuername/>`.
7. Save your changes.

2. Configure Microsoft Entra ID

Context

> ⓘ Note
>
> If you want to register Identity Authentication tenant more than once in Microsoft Entra ID, you must configure issuer name per Identity Authentication application and change the name and certificate on Microsoft Entra ID side.
>
> You have to change the certificates, because by default Microsoft Entra ID generates application specific certificates. On Identity Authentication side there is one corporate identity provider with one certificate which means that all applications on Microsoft Entra ID side for the same Identity Authentication tenant should use the same certificate for SAML 2.0.

Procedure

1. Create Microsoft Entra ID applications.

2. Update the issuer names.
3. Generate a certificate with a private key for the Microsoft Entra ID applications.

   You can generate a certificate with a private key using OpenSSL with the following command:

   ```
   openssl req -x509 -days 365 -newkey rsa:2048 -keyout cert.pem -out cert.pem
   ```

   The commands are executed in the MS Windows or Mac OS Terminal.
4. Convert the `.pem` file to `.pfx` format.

   You can convert the `.pem` file to `.pfx` format, using the following command:

   ```
   openssl pkcs12 -export -in cert.pem -inkey cert.pem -out cert.pfx
   ```

   The commands are executed in the MS Windows or Mac OS Terminal.
5. Import the generated certificate to your Microsoft Entra ID applications.

Next Steps

Add the generated certificate for the configured corporate identity provider in your Identity Authentication tenant. For more information, see Configure Trust with SAML 2.0 Corporate Identity Provider [page 2560].

1.11.8 Integrating the Service with SAP Task Center

Overview

For the integration scenario of SAP Task Center, you must use the Global User ID of SAP Cloud Identity Services - Identity Authentication as the federation identifier.

The Global User ID specifies an identifier for a user that is unique across technology layers such as user interface, APIs, and security tokens, as well as across products and lines of businesses contributing to a business process in the Intelligent Enterprise.

This attribute is automatically generated by Identity Authentication at user creation, and it can be changed by the admin after that. It can be provisioned to various SAP cloud solutions by Identity Provisioning.

> → Remember
>
> When Identity Authentication uses a corporate identity provider (IdP) to authenticate the users, the *Enable the Use Identity Authentication user store* option under the *Identity Federation* configuration of the corporate IdP must be enabled, and the users must exist in the Identity Directory, the local user store of Identity Authentication.

The Global User ID addresses the challenge of integrating user-related data across system boundaries. SAP Task Center is an example of a service, which requires the use of the Global User ID as a common user identifier. SAP Task Center provides a single entry point for business users to access their tasks. This scenario needs an enterprise-wide mapping of users to relate tasks to each other in different systems.

> ### Note
>
> Use the Global User ID as a common user identifier for SAP if you expect to use applications, which require one identifier in all solutions like SAP Task Center. For more information, see System Integration Guide for SAP Cloud Identity Services and SAP Task Center.

Usage

Identity Authentication

For every newly created user (self-registered, imported, or manually created - via the administration console or API), Identity Authentication generates a Global User ID. It is unique and can be changed later by the tenant administrator.

The system generated attribute value is 36 characters long (32 hexadecimal characters and 4 hyphens).

> ### Example
>
> f81d4fae-7dec-11d0-a765-00a0c91e6bf6

This attribute can be sent from Identity Authentication to applications as a user attribute, `Subject Name Identifier`, and default attribute in the SAML assertion. The Global User ID is also put in the `id_token` if the application uses OpenID connect.

Identity Provisioning

Identity Provisioning supports provisioning users with Global User ID for the following SAP cloud solutions:

- SAP Ariba
- SAP Fieldglass
- SAP SuccessFactors
- SAP S/4HANA Cloud Public Edition
- SAP S/4HANA through SAP Application Server ABAP
- SAP Marketing Cloud
- SAP Integrated Business Planning
- SAP BTP ABAP Environment

> ### Note
>
> In the context of SAP Task Center, those solutions are known as SAP task providers. For more information about the availability of the SAP task provider solutions integrated with SAP Task Center, refer to SAP Note: 2977611.

The Global User ID is provisioned by the Identity Provisioning using the SCIM attribute `userUuid` as part of the `urn:ietf:params:scim:schemas:extension:sap:2.0:User` namespace.

SAP Identity Management

SAP Identity Management (on-premise solution) supports reading users with Global User ID from Identity Authentication using the Identity Management *SCI* connector. SCI stands for SAP Cloud Identity, the former

name of Identity Authentication. It is not possible to use the Identity Management SCIM connector in a hybrid scenario with Identity Provisioning for that purpose.

Once loaded in SAP Identity Management, users with Global User ID can be provisioned to SAP S/4HANA on-premise systems only. In this case, the Identity Management *ABAP* or *BusinessSuite* connectors are used.

When SAP Identity Management provisions a new user to Identity Authentication, the Global User ID is generated by the service and returned back as a response. It is stored in the Identity Management MX_USER_UUID attribute.

For more information on how to provision the Global User ID from your SAP Identity Management system to your SAP S/4HANA on-premise system, refer to SAP Note 3047993.

1.11.9 Hybrid Scenario: SAP Identity Management

You can execute hybrid scenarios between provisioning systems from the Identity Provisioning UI and external systems that support SCIM 2.0 protocol.

Prerequisites

- You have an Identity Provisioning service standalone or bundle tenant.
- You have the user credentials to connect SAP Identity Management to SAP Cloud Identity Services - Identity Provisioning. Your user has read and write permissions.

Context

A proxy system is a special connector type you can use for *hybrid* scenarios. It exposes any Identity Provisioning supported backend system as a SCIM 2.0 service provider, which can be consumed by any SCIM 2.0 compatible client application, without making a direct connection between them.

The Identity Provisioning proxy system will initially provision entities to an external consumer system and then will start executing CRUD operations backwards, whenever the external system requests such. For more information, see Proxy Systems [page 1343].

The scenario below is exemplary. It involves a proxy connector you have added in the Identity Provisioning UI, and **SAP Identity Management** as an external leading identity management system.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services
2. Create a technical user with the necessary authorizations. It will later be used by the external leading identity management system to connect to Identity Provisioning.
    1. In SAP Cloud Identity Services admin console, navigate to *Users & Authorizations* > *Administrators*.
    2. Add an administrator user of type **System** and configure the basic authentication method for this user. If you already have a technical user, skip this step.
    3. Save your changes.
    4. Select your administrator user of type **System** and enable the *Access Proxy System API* permission.
    5. Save your changes.
3. Access Identity Provisioning. The access URL depends on the productive type of your Identity Provisioning. See: Access Admin Console [page 542]
4. Add a proxy system. You can choose among a list of systems available for hybrid scenarios with SAP Identity Management. To find the system you need, see Proxy Systems [page 1343] → **More Information**.
5. Open the *Properties* tab of the selected proxy system to configure its connection settings.
6. If necessary, modify the default *Read* and *Write* transformation mapping rules to reflect the current setup of entities in your proxy system.
7. Save your changes.

Next Steps

1. Now, you can export the newly created proxy system. To do that, choose *Export* → *CSV format*.
2. Then, go to SAP Identity Management to register or import a SCIM repository.

> **Note**
>
> If you import the *.csv* file, you will have all the fields automatically filled-in. However:
>
> - You need to manually enter your client ID and secret (AUTH_USER and AUTH_PASSWORD).

- For the SCIM_ASSIGNMENT_METHOD constant, leave its default value: **PATCH**.
  However, check explicitly in the documentation of the relevant proxy system type whether you should leave the default value **PATCH**, or change it to **PUT**. Find your system under section Proxy Systems [page 1343].

3. Then start an *Initial load* job. After the initial load is done, you can create new users or update existing ones in SAP Identity Management.

Future Identity Lifecycle

What happens when you make new changes (create/update/delete an entity)?

- If a new change is made in SAP Identity Management, a new job is automatically triggered. It applies the changes in the external back-end system so that both systems become up-to-date and synchronized.
- If a new change is made in the back-end system, you have to start a new *Initial load* job so that the changes can apply in SAP Identity Management.

1.12 Monitoring and Troubleshooting

This section describes how you can get usage statistics, access audit logs, export change logs or get support if things start to go wrong.

View Usage Statistics [page 2966]

You can view statistical information for a tenant in the administration console for SAP Cloud Identity Services.

Audit Logs [page 2966]
: Tenant administrators can access the audit logs for changes in the personal data, and successful, and failed authentications in Identity Authentication.

Export Change Logs with a History of Administration Operations [page 2976]
: You can download a CSV file with a history of the operations performed by administrators in the administration console for SAP Cloud Identity Services.

Logging OpenID Connect (OIDC) Tokens [page 2980]
: Tenant administrator can view the JWT payload of the OpenID Connect (OIDC) tokens issued or received by Identity Authentication.

Monitor Provisioning Job Logs [page 2982]
: Job logs display information about the execution of provisioning jobs. Each row in the list of job logs shows information about one execution of a job.

Monitor Real-Time Logs [page 2986]
: Real-time provisioning logs display information about the execution of a real-time sync of a user or a group entity.

Monitor Central Store Logs [page 2988]
: Central Store Logs provide information about the application-specific groups that have been provisioned from the Identity Directory to your target systems.

Monitoring with SAP Cloud ALM [page 2991]
: SAP Cloud Identity Services are integrated with SAP Cloud ALM, which is a cloud-based application lifecycle management offering that enables you to implement, operate, and monitor your cloud solutions.

Manage Provisioning Job Logs [page 3010]
: After you view and analyze the provisioning job logs, you can download or delete them.

Manage Job Notifications [page 3018]
: You can subscribe to a source system to receive notification e-mails. They provide information about the job execution and links to download job logs, in case of created, updated, failed, skipped, or deleted entities.

View Troubleshooting Logs [page 3020]
: Tenant administrator can filter and view troubleshooting logs directly in the administration console for SAP Cloud Identity Services to diagnose problems with authentication.

Download Troubleshooting Logs [page 3021]
: Tenant administrator can view Identity Authentication troubleshooting logs to monitor the system, and diagnose and solve problems.

Analyze Troubleshooting Logs with Support Log Assistant 2.0 [page 3022]

Troubleshooting Issues with Authentication and User and Group Management [page 3023]
: While using the Identity Authentication service, you encounter issues or have questions regarding specific settings, limitations, or other aspects.

Troubleshooting Provisioning Issues [page 3070]
: While using the Identity Provisioning service, you might encounter issues or have questions regarding specific settings, limitations, or other aspects.

1.12.1 View Usage Statistics

You can view statistical information for a tenant in the administration console for SAP Cloud Identity Services.

Context

The *Reporting* view displays a chart of statistical information with the number of the user logon requests. A logon request is a single authentication request managed via Identity Authentication. Identity Authentication counts only one logon request per user per day. Logon requests are independent of the authentication mechanism and user type.

The default statistical information shows the usage of the bundled, charged and system applications for the last six months. You can customize what you see by requesting information about specific applications and modifying the period.

Identity Authentication keeps the usage statistics for three years.

> ⓘ Note
>
> If you need statistics for the period before August 2015, you can report an incident on SAP Support Portal Home with a component `BC-IAM-IDS`.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Reporting* tile.
3. **Optional:** Specify the applications that you want to view from the *Logon counters* drop-down.
4. **Optional:** Modify the statistics period.

1.12.2 Audit Logs

Tenant administrators can access the audit logs for changes in the personal data, and successful, and failed authentications in Identity Authentication.

> → Tip
>
> You can find a list of the security events that are logged by Identity Authentication on Auditing and Logging Information [page 2906].

There are two different procedures for accessing the audit logs:

- Access Audit Logs (Audit Log Service in SAP BTP, Cloud Foundry) [page 2967]
- Access Audit Logs (Audit Log Service in SAP BTP, Neo) [page 2972]

1.12.2.1 Access Audit Logs (Audit Log Service in SAP BTP, Cloud Foundry)

Access the audit logs for changes in the personal data, successful, and failed authentications for Identity Authentication tenants on both the SAP, and the AWS and Azure infrastructures in the Audit Log Service in SAP BTP, Cloud Foundry.

Prerequisites

- You have a subaccount in your global account in SAP BTP, Cloud Foundry. For more information, see Create a Subaccount.
- The subaccount region must map your Identity Authentication region.

Context

> ⓘ Note
>
> The content in this document is both for tenants on the SAP, and AWS and Azure infrastructures.

> → Tip
>
> If your tenant is on the SAP infrastructure, when you access the administration console for SAP Cloud Identity Services, the *Audit and Change Logs* tile, you see the *Cloud Foundry*, *NEO*, and *Change Logs* options for configurations. If your tenant is on the AWS, Azure infrastructure, you see the *Audit Logs* and *Change Logs* options for configurations.
>
> Information about the region, representing the data center in which the tenant is located is visible in the header of the administration console. For example, *Cloud Identity Services* `Europe (Frankfurt / Amsterdam)`. For more information about the regions, see Regional Availability [page 11].

The audit log entries in the Audit Log Service in SAP BTP, Cloud Foundry are retained for 90 days. For more information, see Audit Log Retention for the Cloud Foundry Environment.

To view the audit logs, follow the procedures below:

1. Configure the Service Plans

Procedure

1. In the SAP BTP cockpit, navigate to the corresponding subaccount. For more information, see Navigate in the Cockpit.

2. In the navigation area on the left, choose *Entitlements*, then choose *Edit* > *Add Service Plans*.
3. From the dialog, search for and select *Audit Log Viewer Service*, select the *free (Application)* checkbox, and then choose *Add 1 service plan*.
4. Save your changes.

2. Configure Audit Log Viewer Instance

Procedure

1. In the SAP BTP cockpit, navigate to the corresponding subaccount. For more information, see Navigate in the Cockpit.

   > ⚠ Caution
   >
   > The subaccount region must map your Identity Authentication region. Otherwise you'll get an error when you try to access the audit logs directly from the administration console.

2. Navigate to *Services* > *Service Marketplace*, and select *Audit Log Viewer Service*.
3. Choose *Create*.

   In the *New Instance or Subscription* dialog box, **`Audit Log Viewer Service`** for *Service*, and **`free`** for *Plan* are already preselected.
4. Choose *Create* and close the information message.

3. Create and Assign Role Collection and Roles

Procedure

1. In the SAP BTP cockpit, navigate to the corresponding subaccount. For more information, see Navigate in the Cockpit.
2. Choose *Security* > *Roles Collections* in the navigation area.
3. Choose *Create*.
4. Enter name for the new role in the *Create Role Collection* popup and choose *Create*.

   The new role appears in the *Role Collections* list.
5. Select the newly created role collection from the list.
6. Choose the *Edit* button.
7. Under the *Roles* tab, expand the *Role Name* list and select the auditlog viewer and auditlog-management roles.

   If the roles don't exist, create them. For more information, see Configure Application Roles and Assign Roles to Users.

8. Choose *Add*.
9. Navigate back to the subaccount and choose *Security* > *Users* and assign the role collection to the user.

4. Add Configuration in Administration Console and View Audit Logs

Context

> → Remember
>
> You can have only one configuration in the administration for Cloud Identity services. If you want to add a new configuration, you must remove the already configured one, and then follow the steps below to add the new one.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Audit and Change Logs* tile.
3. Choose the *Audit Logs* tab.
4. You have the following options:
   - If your tenant is on the SAP infrastructure, choose the *Cloud Foundry* tab.
   - If your tenant is on the AWS, Azure infrastructure, choose the *Audit Logs* tab.
5. Choose *+Add*.
6. Fill in the required information in the pop up and save your changes.

Configuration	Notes
Tenant ID	Required. The tenant ID of your Cloud Foundry account.
Region	SAP BTP, Cloud Foundry region. You can choose a region from the options in the dropdown. For more information, see the mapping table.
Subdomain	Optional. If you provide it, a link to the *Audit Log Viewer* is added in the *Audit Service Configuration*, and you can access the audit logs directly from the administration console. ⚠ Caution The subaccount region must map your Identity Authentication region. Otherwise you'll get an error when you try to access the audit logs directly from the administration console.

Identity Authentication - Cloud Foundry Regions Mapping

Identity Authentication		Cloud Foundry Regions		
				Default **Note** **The default Cloud Foundry region where logs are sent.**
Region	**Infrastructure**	**Technical Name**	**Name**	
North America (Canada Central) / Canada (Toronto)	azure-canadacentral	cf-ca10	Canada (Montreal)	Yes
US West / West US 2	azure-westus2	cf-us20	US West (WA)	Yes
		cf-us21	US East (VA)	No
		cf-us10	US East (VA)	No
		cf-us30	US Central (IA)	No
US West / East US	azure-eastus	cf-us20	US West (WA)	Yes
Singapore	aws-ap-southeast-1	cf-ap11	Singapore	Yes
		cf-ap21	Singapore	No
South Korea / South Korea (Seoul)	aws-ap-northeast-2	cf-ap12	South Korea (Seoul)	Yes
Europe / Germany (Frankfurt)	aws-eu-central-1	cf-eu11	Europe (Frankfurt) EU Access	Yes
		cf-eu10	Europe (Frankfurt)	No
		cf-eu20	Europe (Netherlands)	No
		cf-eu30	Europe (Frankfurt) GCP	No
Europe / Switzerland	azure-switzerland-north	cf-ch20	Switzerland (Zurich) Azure EU Access	Yes
India (Mumbai)	aws-ap-south-1	cf-in30	India (Mumbai)	Yes
Brazil	aws-sa-east-1	cf-br10	Brazil (São Paulo)	Yes
Europe / Germany (Frankfurt)	eu-de-2	cf-eu10	Europe (Frankfurt)	Yes
		cf-eu11	Europe (Frankfurt) EU Access	No
		cf-eu20	Europe (Netherlands)	No
		cf-eu30	Europe (Frankfurt) GCP	No

Identity Authentication		Cloud Foundry Regions		
				Default **Note** **The default Cloud Foundry region where logs are sent.**
Region	**Infrastructure**	**Technical Name**	**Name**	
Australia (Sydney)	ap-au-1	cf-ap10	Australia (Sydney)	Yes
		cf-ap20	Australia (Sydney)	No
Japan (Tokyo)	ap-jp-1	cf-jp10	Japan (Tokyo)	Yes
		cf-jp20	Japan (Tokyo)	No
US East / East US	na-us-2	cf-us10	US East (VA)	Yes
		cf-us21	US East (VA)	No
Europe / Netherlands (Amsterdam)	eu-nl-1	cf-eu10	Europe (Frankfurt)	Yes
		cf-eu11	Europe (Frankfurt) EU Access	No
		cf-eu20	Europe (Netherlands)	No
		cf-eu30	Europe (Frankfurt) GCP	No
US East / East US	na-us-1	cf-us10	US East (VA)	Yes
		cf-us21	US East (VA)	No

7. Save your changes.

> **Note**
>
> The configuration will be enabled with the next 15 minutes.

> **Caution**
>
> If your SAP Cloud Identity Services tenant is migrated to a new region, you must remove the current configuration and repeat procedure with the new region.

8. View the audit logs. You have two options:
   - (if subdomain is configured) choose the link to the *Audit Log Viewer* in the *Audit Service Configuration* in the administration console.
   - in the cockpit, navigate to *Services* > *Instances and Subscriptions* > *Audit Log Viewer*.

Results

Upon accessing the Audit Log Viewer, you have the option to filter the logs based on date and keyword filters.

The audit logs provide information about the event category and timestamp, the event and object type, who performed the action and others.

> Example
>
> - *Category*: audit.security-events (logged as security event message), audit.configuration (logged as configuration modification message), audit.data-access (logged as data access message).
> - *Event Type*: JOB_TRIGGERED, SYSTEM_UPDATED, SYSTEM_CREATED, SYSTEM_DELETED
> - *Object Type*: Job, System
> - *ObjectAttribute.performed-by-user*: P123456

For more information about the security events that are logged by Identity Authentication, see Auditing and Logging Information [page 2906].

Next Steps

(Optional) Retrieve the audit logs via the Audit Log Retrieval API. See Audit Log Retrieval API Usage for Subaccounts in the Cloud Foundry Environment.

1.12.2.2 Access Audit Logs (Audit Log Service in SAP BTP, Neo)

View the audit logs for changes in the personal data, successful, and failed authentications for Identity Authentication tenants on the SAP infrastructure in the Audit Log Service in SAP BTP, Neo.

Context

> Note
>
> The content in this section is only relevant for tenants on the SAP infrastructure.

> Caution
>
> The deprecation of the access of the audit logs for Identity Authentication tenants on the SAP infrastructure in the Audit Log Service in SAP BTP, Neo has been postponed and will not be carried out according to the previously announced timeline. A new timeline will be announced accordingly.
>
> You can continue using the Audit Log Service in SAP BTP, Neo to access the Identity Authentication tenants on the SAP infrastructures.

→ Tip

If your tenant is on the SAP infrastructure, when you access the administration console for SAP Cloud Identity Services, the *Audit and Change Logs* tile, you see the *Cloud Foundry*, *NEO*, and *Change Logs* options for configurations. If your tenant is on the AWS, Azure infrastructure, you see the *Audit Logs* and *Change Logs* options for configurations.

To view the audit logs, you should generate Client ID and Client Secret for audit logs in the administration console for SAP Cloud Identity Services first. After that you should obtain an access token, and then call the audit log retrieval API to access the data.

The audit log entries in the Audit Log Service in SAP BTP, Neo are retained for 201 days. For more information, see Audit Log Retention API Usage for the Neo Environment.

To access the audit logs, follow the procedures below:

1. Generate Client Credentials for Audit Logs

Context

The Client ID and Client Secret for the current tenant are generated in the administration console for SAP Cloud Identity Services.

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Audit and Change Logs* tile.
3. Choose the *NEO* tab.
4. Under *Generate Client Credentials for Audit Logs* choose the *Generate* button.

   A dialog box with the generated Client ID and Client Secret appears.

   → Remember

   Make sure that you copy the Client Secret from the dialog box. When you choose *OK*, the dialog box closes, and you can't retrieve the Client Secret from the system anymore.

   The generated Client ID can be seen in the *Generate Client Credentials for Audit Logs* section under the *NEO* tab.

   → Tip

   To delete the client credentials, choose the icon next to the generated Client ID. This deletes the Client ID and Client Secret from the system.

2. Obtain an Access Token

Context

Use the Client ID and Client Secret generated for the current tenant in the administration console for SAP Cloud Identity Services to obtain an access token. For more information about how to obtain the access token see **2. Get an OAuth Access Token** in Using Platform APIs.

→ Tip

The URL for the POST request looks like this: `https://api.<SAP BTP Host>/oauth2/apitoken/v1?grant_type=client_credentials`

Cluster	Tenant Region	SAP BTP Host in Request
Europe	Amsterdam	`eu1.hana.ondemand.com` (primary)
		`eu3.hana.ondemand.com`
Australia	Sydney	`ap1.hana.ondemand.com` (primary)
		`jp1.hana.ondemand.com`
Japan	Tokyo/Osaka	`jp1.hana.ondemand.com`
US-East	Sterling/Toronto	`us3.hana.ondemand.com` (primary)
		`us1.hana.ondemand.com`
Saudi Arabia	Riyadh/Dammam	`sa1.hana.ondemand.com`

Use the primary host for your search. If the audit log is not found there, use the other hosts.

For more information, see Regional Availability [page 11] and Regions and Hosts Available for the Neo Environment.

3. Call the Audit Log Retrieval API

Context

To access the audit logs, you should call the audit log retrieval API. You need the Client ID and Client Secret for the current tenant, generated in the administration console for SAP Cloud Identity Services, and the access token. For more information, see Audit Log Retrieval API Usage.

You can filter the audit logs by time and/or categories. The categories that you can filter are:

- audit.authentication - audit logs related to authentication (failed, successful, type)
- audit.data-change - audit logs related to changes in personal data

→ Remember

The URI for the GET request looks like this:

```
https://api.<SAP BTP Host>/auditlog/v1/accounts/<Tenant ID>/AuditLogRecordsIds?
$filter=(Time ge '2018-05-17T13.00.00' and Time le '2018-05-18T05.00.00') and
Category eq '<category>'
```

The timestamp is in Coordinated Universal Time (UTC).

Replace the URI from the examples in Audit Log Retrieval API Usage with the provided one for your Identity Authentication tenant.

Tenant ID is an automatically generated ID by the system. The first administrator created for the tenant receives an activation email with a URL in it. This URL contains the *tenant ID*.

Cluster	Tenant Region	SAP BTP Host in Request	Deprecated
Europe	Amsterdam	`eu1.hana.ondemand.com` (primary)	Oct 23, 2024
		`eu3.hana.ondemand.com`	
Asia Pacific	Sydney/Tokyo	`ap1.hana.ondemand.com` (primary)	Oct 2, 2024
		`jp1.hana.ondemand.com`	Sep 11, 2024
Japan	Tokyo/Osaka	`jp1.hana.ondemand.com`	Sep 11, 2024
US-East	Sterling/Toronto	`us3.hana.ondemand.com` (primary)	Oct 9, 2024
		`us1.hana.ondemand.com`	
Saudi Arabia	Riyadh/Dammam	`sa1.hana.ondemand.com`	Jul 31, 2024

Use the primary host for your search. If the audit log is not found there, use the other hosts.

For more information, see Regional Availability [page 11] and Regions and Hosts Available for the Neo Environment.

Results

For more information about the security events that are logged by Identity Authentication, see Auditing and Logging Information [page 2906].

The procedure outlined above does not display logging information related to Identity Provisioning.

1.12.3 Export Change Logs with a History of Administration Operations

You can download a CSV file with a history of the operations performed by administrators in the administration console for SAP Cloud Identity Services.

Context

The exported change logs are saved in a CSV file and contain information about *CREATE*, *UPDATE*, or *DELETE* operations performed by administrators. The change logs are stored in the data base for 24 months.

Each record should contain the following data:

- *Date*
  The date when the resource was created, updated, or deleted.
- *Administrator's ID*
  The ID of the user or the system that made the change.
- *Administrator's Name*
  The name of the user or the system that made the change.
- *Resource Type*
  This indicates which type of resource was created, updated, or deleted, for example service provider.
- *Resource ID*
  An identifier for the resource.
- *Resource Name*
  The name of the resource that was created, updated, or deleted.
- *Action*
  - *CREATE*
    The log shows the value of the attribute when the resource was created.
  - *UPDATE*
    The log shows the changed value of the attribute when the resource was updated.
  - *DELETE*
    The log shows which resource was deleted.
- *Attribute*
  The attribute of the resource that was created or updated with the relevant operation.
- *Value*
  The new value of the attribute.

> **Note**
>
> There are attributes whose values cannot be displayed in the logs. In such cases the value fields are left blank.

> **Example**
>
> The table shows change logs for the following operations:
>
> 1. A tenant administrator, Donna Moore, creates a Company A application.

2. The tenant administrator uploads service provider metadata for the SAML 2.0 trust.
3. The tenant administrator creates custom Company A terms of use by uploading a plain text file.
4. The tenant administrator creates a custom Company A privacy policy by uploading a plain text file.
5. The tenant administrator allows user self-registration for an application of the configured service provider as she uses the default email template for the self-registration process.
6. The tenant administrator configures a branding style for the application.
7. The tenant administrator sets *SAP Community Password Policy v.1.1* for the application .
8. The tenant administrator sets *Company A Terms of Use* for the application.
9. The tenant administrator sets *Company A Privacy Policy* for the application.

Sample Change Logs Data

Date	Administrator's ID	Administrator's Name	Resource Type	Resource ID	Resource Name	Action	Attribute	Value
16-05-2014 10:21:21	P123456	Donna Moore	Service Provider	500964f6e4b0f3cba101f700	sp.example.com	UPDATE	Privacy Policy	Company A Privacy Policy

To download a CSV file with change logs information, proceed as follows:

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose the *Audit and Change Logs* tile.
3. Under *Export Change Logs* choose the *Export* button.

Results

You have downloaded a CSV file containing history of operations for the tenant administration, and for the configurations of identity providers and service providers.

1.12.4 Logging OpenID Connect (OIDC) Tokens

Tenant administrator can view the JWT payload of the OpenID Connect (OIDC) tokens issued or received by Identity Authentication.

Prerequisites

You have the Identity Authentication troubleshooting logs with severity **`INFO`**. For more information, see View Troubleshooting Logs [page 3020] or Download Troubleshooting Logs [page 3021].

Context

Identity Authentication can issue OpenID Connect (OIDC) tokens to the applications, and receive tokens. The received tokens can be either tokens from the corporate identity provider, or from Identity Authentication itself. When Identity Authentication issues or receives tokens, it logs the payload of that token.

Message Information

Key	Value	Additional Info
`state`	successful	The token is issued or received.
`action`	issueJwtToken | receiveJwtToken	For issued or received tokens.
`objectType`	openIdClient	

Key	Value	Additional Info
`objectId`	<the `client ID` of the application>	Unique attribute of the objectType – either id, or name, etc.
`category`	audit.authentication	
`jwtPayload`	<JWT claims>	A JSON string, which contains the token claims of issued or received OpenID Connect (OIDC) tokens. **Note** Claims that aren't relevant for troubleshooting are removed from the log for the sake of brevity: `iat`, `exp` and `jti`.
`workflow`	openIdConnect	

`userIdentifier`	<the user identifier>	• The local user ID (P number generated by Identity Authentication).
		• For proxy scenarios:
		  • the local user ID (if *Use Identity Authentication user store* option is enabled and the user is found locally)
		  • the user identifier received from the corporate identity provider (if *Use Identity Authentication user store* is disabled or the user isn't found locally)

`grant_type`	<the respective grant type>	
`serviceProvider`	<the name of the application>	

Example

Message

```
state=successful, action=issueJwtToken, objectType=openIdClient,
objectId="e8b77d3e-e6ba-4fb6-a577-e92d9ecab567", category=audit.authentication,
jwtPayload="{"sub":"P123456","aud":["<the audience claim>"],"scim_id":"b12a0234-
b1b0-41f8-9a2b-dc7395aaaa77","user_uuid":" b12a0234-b1b0-41f8-9a2b-
dc7395aaaa77","user_name":"P123456","azp":"e2b34d3e-e6ab-4fb6-s37-
e92d9ecab567","last_name":"Moore","first_name":"Dona","email":"dona.moore@example
.com","sid":"S-SP-fbf690ce-ce77-464f-b4b3-06adf3312c86"}",
workflow=openIdConnect, userIdentifier=P123456, grant_type=authorization_code,
serviceProvider=myapplication
```

1.12.5 Monitor Provisioning Job Logs

Job logs display information about the execution of provisioning jobs. Each row in the list of job logs shows information about one execution of a job.

Prerequisites

- You have enabled and set up a source and a target system in the Identity Provisioning UI. Make sure all mandatory properties are configured correctly. See: Enable and Disable Systems [page 2419]
- You have run a provisioning job. See: Start and Stop Provisioning Jobs [page 2472]
- Your Identity Provisioning tenant must run on SAP Cloud Identity Services infrastructure to be able to search for job logs.

Procedure

To search and view the job logs, proceed as follows:

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. In the *Job Execution Logs* screen, search for a job log and select it. You can search by system name, job type and status.
   Each row in the list of job logs displays the following information:

Column	Details
Source System	The source system the job was triggered for.
Job Type	The job type can be **READ**, **RESYNC** and **SIMULATE**.
Trigger Type	The triggering type for the job. It can be: • **IMMEDIATE** – for manually triggered jobs after choosing *Run Now* or for restarted jobs which were in previous status **Pending Restart**. • **REPEAT** – for scheduled jobs after choosing *Schedule*.

Column	Details
Status	The status of the job. • **Success** – provisioning job has finished successfully. • **Finished with Error** – provisioning job has finished with error. Some entities failed to be read or written, connection to the source system failed or reading from the source system encountered an issue. • **Running** – provisioning job is still running and has not encountered any issues so far. • **Running with Error** – provisioning job is still running, but some entities already failed. • **Manually Terminated** – provisioning job is manually stopped by Identity Provisioning administrator. • **Pending Restart** – provisioning job is temporary paused due to external reasons, not related to your direct interaction (for example, when Identity Provisioning is currently down). When the state gets back to normal, the job will automatically resume with a new job ID, continuing from the last processed entity. Its status will switch over to **Running** or **Running with Error**. Note that, if a provisioning job from a source system to multiple target systems stops due to an error in one of the targets, it will not resume for that specific target upon restart.
Start Time	Date, time, and timezone in UTC format when the job is started.
End Time	Date, time, and timezone in UTC format when the job is finished.
Action	Allows you to stop a running provisioning job by choosing the *Stop Job* button .

3. In the *Job Execution Details* screen, view the following details about a given job:
   - **<System_Name>** – Shows the source system name.
   - **Job Type** - Shows the type of the job, as described in the table above.
   - **Read Mode** - Shows the mode of the job. It can be:
     - **Full Read**
     - **Delta Read**
       The read mode considers how job-related properties, such as: `ips.delta.read` and `ips.full.read.force.count`, are configured on the source system.
       For example, if your system works in delta read mode and you set up ips.full.read.force.count=10, the *Job Execution Details* screen will display 10 consecutive jobs with *Read Mode:Delta Read* followed by one with *Read Mode:Full Read*.

       > ### Note
       >
       > **Resync** and **Simulate** jobs (the latter is available for Identity Provisioning tenants on SAP Cloud Identity Services infrastructure) will always have Read Mode: Full Read. Migration jobs does not display read mode.
   - **Trigger Type** - Shows the trigger type, as described in the table above.

- **Triggered By** - Shows who triggered the job. This field is displayed for jobs of type `Read`, `Resync`, and `Simulate` when the trigger type is IMMEDIATE.
  - User ID (for example, *P000000*) – The ID of the user who manually triggered a `Read`, `Resync`, and `Simulate` job.
  - *Identity Provisioning API* – `<uuid/username>` – The UUID or username of the technical user who triggered a `Read` or `Resync` job via an API client. For more information, see Run Provisioning Jobs via API [page 2480]
  - *Identity Provisioning Internal API* – SAP internal API.

> **Note**
>
> Scheduled jobs don't display the *Triggered By* information.

- **Start Time** and **End Time** - Shows the job start and end time, as described in the table above.
- **Error Message** – Shows the error message.
- **Job Execution Outcome** - Shows the job execution specifics that have influenced the deletion of entities from the target system(s) at the end of the provisioning job.
- **Statistics** – Shows the job statistics, that is, details about how entities are handled.

> **Note**
>
> Note that if an entity type is set to be ignored in the transformations, you won't get any data in the job log statistics for this entity type.

Column	Source System	Target System
Entity	Type of the entity (user, group)	Type of the entity (user, group)
System	Name of the source system	Name of the target system
Action	Action executed on the system: *Read*	Action executed on the system: *Write*
Read	Number of read entities	Not applicable
Created	Not applicable	Number of created entities
Updated	Not applicable	Number of updated entities
Deleted	Not applicable	Number of deleted entities

Column	Source System	Target System
Skipped	Number of skipped entities from the source system Entities can be skipped if they don't fulfill a condition in the read transformation. **Example** Setting this group condition in the read transformation results in skipping all read groups that do not match the specified display name. **Code Syntax** `"condition": "$.displayName == 'Employee'",`	Number of skipped entities in the target system Entities can be skipped if they don't fulfill a condition in the write transformation. An application-specific group is skipped if you try to perform an operation which is not supported for it. For more information about the *supportedOperations* attribute, see Groups [page 514]. **Example** Setting this group condition in the write transformation results in skipping all groups that do not match the specified display name. **Code Syntax** `"condition": "$.displayName == 'Employee'",`
Failed	Number of entities failed during the read operation from the source system	Number of entities failed to be created, updated or deleted in the target system

- **Failed Entities** – Shows additional information about the failed entities. A maximum number of ten entities can be displayed per job log. In case you need to view the full job log, download it from the *Download All Error Logs for This Job* button. For more information see: Manage Provisioning Job Logs [page 3010]

Related Information

Start and Stop Provisioning Jobs [page 2472]
Manage Job Notifications [page 3018]

1.12.6 Monitor Real-Time Logs

Real-time provisioning logs display information about the execution of a real-time sync of a user or a group entity.

Prerequisites

- Your Identity Provisioning tenant is running on SAP Cloud Identity infrastructure.
- You have configured the real-time provisioning scenario. For more information, see Real-Time Provisioning in SAP Cloud Identity Infrastructure
- Your source and target systems are enabled. For more information, see Enable and Disable Systems [page 2419]

Procedure

You can search, view, refresh and configure a retention period of real-time provisioning logs. Proceed as follows:

1. Sign in to the SAP Cloud Identity Services administration console and select *Identity Provisioning* > *Provisioning Logs* > *Real-Time Logs* .
2. In the *Real-Time Provisioning Execution Logs* screen, search for a log and select it. You can search by source system name, entity ID, entity type and status.
   Each row in the list of logs displays the following information about one execution of a real-time sync.

Column	Details
Source System	The name of the source system the real-time provisioning is triggered from. For example: *IAS_Source*
Entity ID	The entity ID of the user or the group in the target system. For example: *baba3ba7-35f0-4567-b507-ce5555c11bbb* If the entity ID is missing, this means that the real-time provisioning has failed. It happens when something goes wrong with the source system. For example, the source system is disabled or establishing the connection to the source system has failed due to incorrect URL. In this case, you get the log without the entity ID.
Entity Type	The entity type: user or group.

Column	Details
Status	The status of the real-time provisioning. For example: • *Finished Successfully* - Real-time provisioning finished successfully. A user or a group is successfully created, updated or deleted real time. • *Finished with Error* - Real-time provisioning finished with error. A user or a group failed to be created, updated or deleted real time.
Start Time	Date, time, and time zone in UTC format when the real-time sync is triggered. For example: *28/Jun/2023 09:19:00 +03*

3. In the *Real-Time Log Details* screen, view the following details under the `<Source System>` name: log type (*Real Time*), entity ID (if it is available), start time, status, error message and *Result on Source and Target System* tables.

Column	Details
Source System	The name of the source system from which the real-time provisioning was triggered. For example: *IAS_Source*
Target System	The name of the target system for which the real-time provisioning was triggered. For example: *Concur_Target*
Operation	The type of the operation. • *CREATE* • *UPDATE* • *PATCH* • *DELETE*
State	The state of the entity when real-time provisioning is triggered. • *Entity Created* • *Entity Updated* • *Entity Skipped* • *Entity Already Provisioned* • *Entity Failed* • *Entity Read* • *Entity Deleted* • *Entity Not Provisioned*

Column	Details
Additional Information	Additional information about the failed entity. If the target system is SAP BTP XS Advanced UAA (Cloud Foundry), the *Additional Information* column shows the origin of the users that have been created, updated or deleted.
Reason	• **Reason (Source System)**: Specifies that the entity was skipped and will to be deprovisioned from the target system. • **Reason (Target System)**: Specifies that the entity was skipped and has been deprovisioned from the target system.

4. (Optional) Choose *Refresh* to get the latest updates of the real-time provisioning logs.
5. Choose *Configure* to define the retention period of real-time provisioning logs.
   Set a period (7, 14 or 30 days). Logs which are older than this period will be automatically deleted. By default, job logs are kept for 7 days.

> ⚠ Restriction
>
> Note the following restrictions about the real-time provisioning logs:
>
> - You cannot delete them manually.
> - You cannot download them.
> - You cannot subscribe to a source system to receive notifications about their status.

1.12.7 Monitor Central Store Logs

Central Store Logs provide information about the application-specific groups that have been provisioned from the Identity Directory to your target systems.

Prerequisites

- You have configured the Local Identity Directory as a source system, linked it to a target system, and run at least one provisioning job. For more information, see Start and Stop Provisioning Jobs [page 2472].
- You have created an application under *Applications & Resources*, and set its application ID as the value of the `ips.application.id` property in the target system.
- You have enabled the *Central Store-Based Provisioning* option under *Applications & Resources* > *Application* > *Provisioning*.

Procedure

You can search, view and refresh central store logs.

1. Sign in to the SAP Cloud Identity Services administration console and select *Identity Provisioning* > *Provisioning Logs* > *Central Store Logs*.

   > ⓘ Note
   >
   > *Central Store Logs* are enabled and will appear under *Provisioning Logs* whenever changes to application-specific groups occur in the Identity Directory, such as assigning users or modifying group attributes.

2. In the *Central Store Provisioning Logs* screen, search for a log and select it. You can search by target system name, application ID, target entity ID, source entity ID and status.
   Each row in the log list provides information about a single execution of central store-based provisioning.

Column	Details
Target System	The name of the target system to which the central store-based provisioning is triggered. For example: *Fieldglass_Target*
Application ID	The ID of the application the application-specific group belongs to. It is configured as a value of the `ips.application.id` property in the target system.
Source Entity ID	The entity ID of the group in the source system, that is Identity Directory. For example: *4200a79f-228b-4fcd-ab15-46d2d78360f6*
Target Entity ID	The entity ID of the group in the target system. For example: *baba3ba7-35f0-4567-b507-ce5555c11bbb* If the target entity ID is missing, it means that the central store-based provisioning has failed. This can occur, for example, when the group is not found or when multiple groups with the same display name are found in the target system.
Entity Type	The entity type: group.

Column	Details
Status	The status of the central store-based provisioning For example: • *Finished Successfully* - Central store-based provisioning finished successfully. A group is successfully updated. • *Finished with Error* - Central store-based provisioning finished with error. A group failed to be updated.
Start Time	Date, time, and time zone in UTC format when the central store-based provisioning is triggered For example: *28/Jan/2025 09:34:21 +02*

3. In the *Central Store Provisioning Log Details* screen, view the following details under the `<Target System>` name:
   - *Log Type*: Central Store Provisioning Log Details
   - *Source System*: The name of the source system
   - *Entity Type*: group
   - *Source Entity ID*: The group ID in the source system
   - *Target Entity ID*: The group ID in the target system
   - *Application ID*: The ID of the application the application-specific group belongs to.
   - *Start Time*: Date, time, and time zone in UTC format when the central store-based provisioning is triggered
   - *Status*: The status of the central store-based provisioning

Column	Details
Target System	The name of the target system to which the central store-based provisioning is triggered. For example: *Fieldglass_Target*
Operation	The type of the operation. • *CREATE* - This operation occurs when a group is created in the target system. • *UPDATE* - This operation occurs when a group is updated in the target system. • *DELETE*- This operation occurs when a group is deleted in the target system.

Column	Details
State	The state of the entity when central store-based provisioning is triggered. • *Entity Created* • *Entity Updated* • *Entity Failed* • *Entity Deleted*
Additional Information	Additional information about the failed entity.

4. (Optional) Choose *Refresh* to get the latest updates of the central store-based provisioning logs.

1.12.8 Monitoring with SAP Cloud ALM

SAP Cloud Identity Services are integrated with SAP Cloud ALM, which is a cloud-based application lifecycle management offering that enables you to implement, operate, and monitor your cloud solutions.

Initial Configuration

You can request SAP Cloud ALM on SAP for Me for yourself or for all customers for whom you have permissions.

After you've requested SAP Cloud ALM, follow the steps to set it up. For more information, see Required Setup for SAP Cloud ALM.

To use the SAP Cloud ALM apps you must activate the data collection for the *Identity Authentication* and/or *Identity Provisioning* component. For more information, see Setup for SAP Cloud Identity Services – Identity Authentication and Setup for SAP Cloud Identity Services – Identity Provisioning.

Configuration & Security Analysis

With the Configuration & Security Analysis app of SAP Cloud ALM, you can check if your Cloud Identity tenants and provisioning systems are configured in alignment with the Security Recommendations - Identity Authentication and Security Recommendations - Identity Provisioning and Monitoring with SAP Cloud ALM [page 2991].

> **Note**
>
> Identity Authentication and Identity Provisioning report data to SAP Cloud ALM daily. For more information, see Monitor Security Recommendations with SAP Cloud ALM.

Cloud Identity services report security configurations that are directly linked to the SAP BTP Security Recommendations. You can find details about the security configurations in the Security Recommendation

Compliance [page 2992] table below. The Configuration & Security Analysis Details [page 3002] table, in turn, shows the security configurations on your tenant that are not linked to the security recommendations.

Security Recommendation Compliance

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Provisioning	`audit_logs`	The *Data Record* displays the following information as displayed in the *Audit Logs* tab in the administration console for SAP Cloud Identity Services: • Tenant ID • Region • Subdomain If there is no audit logs configuration, the value is empty.	*COMPLIANT* - in case there are audit logs configurations *NONCOMPLIANT* in the following cases: • there is no audit log configuration • you have a stand-alone tenant	BTP-IPS-0001
Identity Provisioning	`trace_setting`	The *Data Record* displays the values set for the properties that enable logging and tracing for personal and sensitive data of the provisioned entities: • `ips.trace.failed.entity.content` = *<value>* • `ips.trace.skipped.entity.content` = *<value>* • `ips.trace.created.entity.content` = *<value>* • `ips.trace.updated.entity.content` = *<value>*	*COMPLIANT* - when all listed properties are set to *false* *NONCOMPLIANT* – if one or more of these properties are set to *true*	BTP-IPS-0002

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Provisioning	`outbound_authentication_method`	The *Data Record* displays the values set for the properties `Authentication` or `ldap.authentication`. If there is no authentication property configured, the value is empty.	*COMPLIANT* in the following cases: • The system supports certificate authentication and the authentication property is set to *ClientCertificateAuthentication*. • The system supports **only** basic authentication and the `Authentication` property is set to *BasicAuthentication*. *NONCOMPLIANT* in the following cases: • There is no authentication property configured. **Note** This requirement is not applicable to the Local Identity Directory, as it does not require configuration of an authentication property. Therefore, it should not be considered noncompliant.	BTP-IPS-0003

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
			• The system supports certificate authentication, but the value of the `Authentication` property is different from *ClientCertificateAuthentication* or the certificate is not configured.	
Identity Provisioning	`inbound_authentication_method`	• *Basic Authentication* • *Certificate Authentication* **Note** The compliance check is relevant on the tenant level.	*COMPLIANT* in the following cases: There is a system user with configured certificate that possesses at least one of the roles: *Access Real-Time Provisioning API* or *Access Proxy System API*. *NONCOMPLIANT* when: There is no system user with configured certificate that possesses at least one of the roles: *Access Real-Time Provisioning API* or *Access Proxy System API*.	BTP-IPS-0004

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Provisioning	`secure_protocols`	The *Data Record* displays the values of all configured **URL** properties. If no URL properties are configured, the value is empty.	*COMPLIANT* in the following cases: • The system uses `ProxyType` *Internet* and the secure protocols used are *HTTPS* or *SSH*. • The system uses `ProxyType` *OnPremise*, hence insecure protocols are accepted. • If there are no **URL** properties configured. *NONCOMPLIANT* when the system uses `ProxyType` *Internet* and the protocol is insecure (for example *HTTP*).	BTP-IPS-0005

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Provisioning	`credential_properties`	The check validates whether for the configuration of sensitive information are used credential properties. The information is displayed in the following format: `sensitive property = <value>` The possible values are: • `true` - when the property is created as `Credential` For example, if you have configured `Password` as `Credential`, the result is `Password = true` • `false` - if the property is not created as `Credential` For example, if you have configured `ssh.password` as `Standard`, the result is `ssh.password = false` empty - if there are no sensitive properties configured If there are no sensitive properties configured, the value is empty.	*COMPLIANT* in the following cases: • All sensitive properties are configured as type *Credential*. • There are no sensitive properties configured. *NONCOMPLIANT* if one or more sensitive properties are configured as type *Standard*.	BTP-IPS-0006

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Provisioning	`trust_all`	The check evaluates whether the `TrustAll` property is used in productive scenarios. The information is displayed in the following format: `Value` = *<property value>*	*COMPLIANT* when the property `TrustAll` is set to *false*. *NONCOMPLIANT* - when the property `TrustAll` is set to *true*. **Note** The security compliance check is not supported for connectivity destinations in the SAP BTP cockpit.	BTP-IPS-0007
Identity Provisioning	`ips_admin_user_count`	The *Data Record* displays the number of assigned tenant administrators.	*COMPLIANT* when the number of tenant administrators assigned is greater than one. *NONCOMPLIANT*: • In case there is only one tenant administrator assigned.	BTP-IPS-0008
Identity Authentication	`certificate_authentication`	Checks whether the certificate generation and authentication is enabled for each of the user types. If it is, the user types are displayed in a comma separated string: `usertypes`: `employee`,`partner`. If there are no user types for which the setting is enabled, the value is empty.	*COMPLIANT* - if there is at least 1 user type for which the setting is enabled. *NONCOMPLIANT* - if there are no user types for which the setting is enabled.	BTP-IAS-0006

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Authentication	`audit_logs`	Checks whether there is an audit log configuration. If there is, the value is *CONFIGURED*. If there is not, the value is `empty`.	*COMPLIANT* - in case there are audit logs configurations. *NONCOMPLIANT* - in case there are *NO* audit logs configurations.	BTP-IAS-0011
Identity Authentication	`custom_domain`	Checks whether the custom domain is configured. If it is, the value is *CONFIGURED*. If it is not, the value is empty.	*COMPLIANT* - if the custom domain is configured. *NONCOMPLIANT* - if the custom domain is *NOT* configured.	BTP-IAS-0019
Identity Authentication	`mail_server_configuration`	Checks whether there is a custom mail server configured. If the custom mail server is of type AWS, then the value is `aws`, otherwise the value is `custom`. If the there is no custom mail server configuration, the value is empty.	*COMPLIANT* - if the custom mail server is configured. *NONCOMPLIANT* - if the custom mail server is NOT configured.	BTP-IAS-0020
Identity Authentication	`system_notification`	Checks whether the admin console is configured to send emails about expiring certificates, system notifications, and new administrators to specific e-mail addresses, to the email addresses of all administrators or to none. If there are no email recipients, the value is empty. If the number of configured recipients is equal to the number of user admins or the setting to send the notifications to all admins is enabled, the value is `configured`. Otherwise it is `misconfigured`.	*COMPLIANT* - If the number of configured recipients is equal to the number of user admins or the setting to send the notifications to all admins is `enabled`. *NONCOMPLIANT* - If there are no email recipients or if it is `misconfigured`.	BTP-IAS-0022

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Authentication	`admin_console_mfa`	Checks whether multi-factor authentication (MFA) is configured for the administration console. The possible values are: • `delegated_to_corp_idp` - if the administration console is set in full proxy mode and the "Apply Application Configurations" setting of the corporate IdP is disabled. • `configured` - if there is a TFA action configured on either service provider (SP) or on a tenant level. • `misconfigured` - if there is no TFA action configured.	*COMPLIANT* - if there is a TFA action configured. *NONCOMPLIANT* - if there is no TFA action configured. *UNRATED* - if it is delegated to the corporate IdP.	BTP-IAS-0001

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Authentication	`password_policy`	Checks whether a password policy is configured. The possible values are: • `delegated_to_corp_idp` - if the SP is set in full proxy mode. • `standard` - if the password policy is set to the default standard one. • `enterprise` - if the password policy is set to the default enterprise one. • `custom` - if a custom password policy is configured. • `empty` - if there is no password policy set.	*COMPLIANT* - if the password policy is either custom or enterprise. *NONCOMPLIANT* - if the password policy is either standard or none is set. *UNRATED* - if it is delegated to the corporate IdP.	BTP-IAS-0002
Identity Authentication	`user_application_access`	Checks the access of end users to the application. The possible values are: • `public` - Everyone can access the application; new users can register using the self-registration process. • `internal` - Only existing users can access the application. • `private` - Only users registered by the application can log on. • empty - If the property is inherited from the parent application.	*COMPLIANT* - if the access is restricted only to existing users. `value=internal`. *NONCOMPLIANT* - `value=public` or `value=private` or the value is inherited from the parent application.	BTP-IAS-0003

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Authentication	`social_sign_on`	Checks whether social sign-on (SSO) is enabled. If it is enabled, the value is *ON*. If it is disabled, the value is *OFF*. The value is empty if the property is inherited from the parent application.	*COMPLIANT* - if SSO is disabled. *NONCOMPLIANT* - if SSO is enabled. *UNRATED* - if it is inherited from the parent application.	BTP-IAS-0005
Identity Authentication	`disable_password_authentication`	Checks whether the default authentication method for end users to authenticate with the service is *user name* and *password*. The possible values are: • empty - if the configured IdP is not the default local IdP, or there is no RBA configuration, or there are no RBA rules. • `configured` - in case the configuration matches the described in the *COMPLIANT* status . • `partially configured` - the default action of the RBA configuration is either *Allow* or *TFA* and there is a RBA rule with action *Deny* which only has authentication method set to *User Name and Password* and there is a RBA rule with action different from *Deny*.	*COMPLIANT* • if the default action of the RBA configuration and the actions of all the RBA rules is *Deny*. • the default action of the RBA configuration is either *Allow* or *TFA* and there is a RBA rule with action *Deny* which only has authentication method set to *User Name and Password*. NONCOMPLIANT • if the default action is *Deny* and the action of any of the RBA rules is *Allow* or *TFA* and the authentication method is either not configured or *User Name and Password*. • the default action of the RBA configuration is either *Allow* or *TFA* and there are no RBA rules.	BTP-IAS-0006

Service	Name	Value	Security Recommendation Status	Security Recommendation Index
Identity Authentication	`branding`	Checks whether there is branding of the organization added to the logon screen. The possible values are: • empty - if there is no logo resource configured and the custom CSS is not enabled. • `configured` - if there is logo resource configured or the custom CSS is enabled.	*COMPLIANT* - if there is logo resource configured or the custom CSS is enabled. *NONCOMPLIANT* - if there is no logo resource configured and the custom CSS is not enabled.	BTP-IAS-0021
Identity Authentication	`reCAPTCHA`	Checks whether self-registration and CAPTCHA are enabled. The possible values are: 1. empty if CAPTCHA is not enabled. 2. configured: if CAPTCHA is enabled for at least the registration form or the login page.	COMPLIANT - if the self-registration is disabled or CAPTCHA is enabled. NONCOMPLIANT - if self-registration is enabled or CAPTCHA is disabled.	BTP-IAS-0025
Identity Authentication	`use_identity_auth_user_store`	Reports whether the *Use Identity Authentication user store* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled	*COMPLIANT* - if enabled. *NONCOMPLIANT* - if disabled.	BTP-IAS-0015

Configuration & Security Analysis Details

Service	Name	Value
Identity Authentication	`ID`	Reports the Id of the service provider or corporate identity provider (IdP).
Identity Authentication	`TYPE`	Reports the type of the service provider (`SYSTEM_APP`, `BUNDLED_APP` or `CHARGED_APP`) or `CORPORATE_IDP` for corporate IdPs.
Identity Authentication	`NAME`	Reports the name of the service provider or corporate IdP.

Service	Name	Value
Identity Authentication	`days_without_mfa_prompt`	Reports the number of days for which the users will not get prompted for second-factor authentication, if they sign in from the same browser. If the property is not configured, the value is empty.
Identity Authentication	`self_registration_link_lifetime_seconds`	Reports the validity of the link sent to user for self registration in seconds.
Identity Authentication	`on_behalf_link_lifetime_seconds`	Reports the validity of the link sent to user for on-behalf registration in seconds.
Identity Authentication	`invitation_link_lifetime_seconds`	Reports the validity of the link sent to user for invitation in seconds.
Identity Authentication	`forgot_password_lifetime_seconds`	Reports the validity of the link sent to user for forgotten password in seconds.
Identity Authentication	`reset_password_lifetime_seconds`	Reports the validity of the link sent to user for password reset in seconds.
Identity Authentication	`locked_password_lifetime_seconds`	Reports the validity of the link sent to user for locked password in seconds.
Identity Authentication	`initial_password_token_lifetime_seconds`	Reports the validity of the initial password set to user in seconds.
Identity Authentication	`idp_initiated_sso`	Reports whether the IdP-initiated Single Sign On (SSO) is enabled. If it is enabled, the value is *ON*. Otherwise the value is *OFF*.
Identity Authentication	`manage_identity_provisioning_admin_count`	Reports the count of users and systems authorized to access the Application Configuration API for running Identity Provisioning jobs or downloading job logs. **Example** `systems=0;users=1`
Identity Authentication	`read_users_admin_count`	Reports the count of users and systems authorized to read and export users. **Example** `systems=0;users=1`

Service	Name	Value
Identity Authentication	`manage_applications_admin_count`	Reports the count of users and systems authorized to configure applications. **Example** `systems=0;users=1`
Identity Authentication	`manage_users_admin_count`	Reports the count of users and systems authorized to manage, export, and import users. **Example** `systems=0;users=1`
Identity Authentication	`manage_corp_idp_admin_count`	Reports the count of users and systems authorized to configure corporate identity providers. **Example** `systems=0;users=1`
Identity Authentication	`manage_groups_admin_count`	Reports the count of users and systems authorized to manage user groups. **Example** `systems=0;users=1`
Identity Authentication	`manage_tenant_configuration_admin_count`	Reports the count of users and systems authorized to manage tenant configuration and authorization assignment to users. **Example** `systems=0;users=1`
Identity Authentication	`default_rba_auth_action`	Reports the default action set in the RBA configuration of the application. The possible values are: • *Allow* • *Deny* • *TFA*
Identity Authentication	`default_authenticating_idp_id`	Reports the `id` of the configured corporate IdP.
Identity Authentication	`default_authenticating_idp_name`	Reports the name of the configured corporate IdP.

Service	Name	Value
Identity Authentication	`default_authenticating_idp_display_name`	Reports the display name of the configured corporate IdP.
Identity Authentication	`default_authenticating_idp_type`	Reports the type of the configured corporate IdP.
Identity Authentication	`trust_all_corporate_idp`	Reports whether the *Trust All Corporate Identity Providers* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`allow_ias_users_log_on`	Reports whether the *Allow Identity Authentication Users Log On* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`spnego_enabled`	Reports whether the *SPNEGO Authentication* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`biometric_authentication_enabled`	Reports whether the *Biometric Authentication* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`force_authentication`	Reports whether the *Force Authentication* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`default_signing_algorithm`	Reports the *Signing Algorithm* configuration. The possible values are: • *SHA-1* • *SHA-256* • *SHA-512*
Identity Authentication	`concurrent_access`	Reports the Concurrent Access configuration. The possible values are: • *Allow* • *Warning* • *Error*
Identity Authentication	`identity_provider_id`	Reports the `id` of the corporate IdP.

Service	Name	Value
Identity Authentication	`identity_provider_name`	Reports the name of the corporate IdP. The value is empty if not configured.
Identity Authentication	`identity_provider_display_name`	Reports the display name of the corporate idP.
Identity Authentication	`identity_provider_type`	Reports the type of the corporate IdP. Possible values are: • *MS_ADFS_2.0 (Microsoft ADFS / Entra ID (SAML 2.0))* • *SAML_2.0 (SAML 2.0 Compliant)* • *OPENID_CONNECT (OpenID Connect Compliant)NW_SSO (SAP Single Sign-On (SAML 2.0))*
Identity Authentication	`forward_all_sso_requests`	Reports whether the *Forward All SSO Requests to Corporate IdP* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`allow_identity_auth_users_only`	Reports whether the *Allow Identity Authentication users only* setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`apply_app_auth_configs`	Reports whether the "Apply Application Configurations" setting is enabled. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`logout_redirect_url`	Reports *Logout Redirect URL*. The value is empty if not configured.
Identity Authentication	`default_signing_algorithm`	Reports the *Signing Algorithm* configuration only if the type is `NOT OPENID_CONNECT`. The possible values are: • *SHA-1* • *SHA-256* • *SHA-512*
Identity Authentication	`sign_authentication_requests`	Reports whether the *Sign authentication requests* setting is enabled only if the type is `NOT OPENID_CONNECT`. • *ON*- if enabled • *OFF* - if disabled

Service	Name	Value
Identity Authentication	`sign_logout_messages`	Reports whether the *Sign single logout messages* setting is enabled only if the type is `NOT OPENID_CONNECT`. The possible values are: • *ON*- if enabled • *OFF* - if disabled
Identity Authentication	`PRIORITY`	Reports the index of the rule based on priority.
Identity Authentication	`IDENTITY_PROVIDER_ID`	Reports the id of the corporate IdP.
Identity Authentication	`IDENTITY_PROVIDER_NAME`	Reports the name of the corporate IdP. Empty if not configured.
Identity Authentication	`IDENTITY_PROVIDER_DISPLAY_NAME`	
Identity Authentication	`USER_TYPE`	Reports the user type of the rule. Possible values are: `employee`, `public`, `partner`, `customer`, `external`, `onboardee`, `alumni`. The value is empty if not configured.
Identity Authentication	`USER_GROUP`	Reports the name of the group. The value is empty if not configured.
Identity Authentication	`USER_EMAIL_DOMAIN`	Reports the email domain of the rule. The value is empty if not configured.
Identity Authentication	`IP_NETWORK_RANGE`	Reports the IP network range of the rule in CIDR format. **Example** `10.10.10.10/11` The value is empty if not configured.
Identity Authentication	`PRIORITY`	Reports the index of the rule based on priority.
Identity Authentication	`IP_NETWORK_RANGE`	Reports the IP network range of the rule in CIDR format. **Example** `10.10.10.10/11` Empty if not configured.

Service	Name	Value
Identity Authentication	IP_FORWARD_RANGE	Reports the IP forward range of the rule in CIDR format. **Example** `10.10.10.10/11` The value is empty if not configured.
Identity Authentication	ACTION	Reports the action of the rule. The possible values are: - *Allow* - *Deny* - *TFA*
Identity Authentication	GROUP_TYPE	Reports the name of the group. Possible values are: - *Cloud (Cloud Group)* - *Corporate(On-Premise Group)* - The value is empty if not configured.
Identity Authentication	AUTH_METHOD	Reports the authentication method for the rule. Possible values are: - *CERT(Client Certificate)SPNEGO* - *UID_PW (User Name and Password)* - *TOKEN (Token)* - *SOCIAL_IDENTITY (Social identity Provider)* - *TRUSTED_IDP_SAML_ASSERTION (Trusted IdP SAML Assertion)* - The value is empty if not configured.
Identity Authentication	USER_ATTRIBUTES	Reports the user attributes for the rule in format of `key=value`. The value is empty if not configured.
Identity Authentication	CORPORATE_IDP_ATTRIBUTE	Reports the corporate IdP attribute for the rule in format of `key=value`. The value is empty if not configured.
Identity Authentication	USER_EMAIL_DOMAIN	Reports the email domain of the rule. The value is empty if not configured.
Identity Authentication	PASSWORD_POLICY_NAME	Reports the name of the password policy.
Identity Authentication	PASSWORD_POLICY_STRENGTH	Reports the strength of the password policy.
Identity Authentication	MINIMUM_PASSWORD_LENGTH	Reports the minimum length of characters of the password policy.

Service	Name	Value
Identity Authentication	`MINIMUM_PASSWORD_AGE_HOURS`	Reports the minimum password age in hours.
Identity Authentication	`USER_INACTIVITY_MONTHS`	Reports the maximum user inactivity in months.
Identity Authentication	`PASSWORD_HISTORY_ENTRY_COUNT`	Reports the password history entry count.
Identity Authentication	`FAILED_SIGN_IN_ATTEMPTS`	Reports the failed sign in attempts.
Identity Authentication	`PASSWORD_LOCKED_PERIOD_HOURS`	Reports the password locked period in hours.
Identity Authentication	`REQUIRED_CHARACTER_GROUPS`	Reports the number of the required character groups.
Identity Authentication	`PASSWORD_BEHAVIOUR`	Reports the password behavior of the policy. Possible values are: • *reset* • *change*

Job & Automation Monitoring

In the Job & Automation Monitoring app, you can monitor the execution of your provisioning jobs using specific metrics. The supported provisioning job types are *Read* (immediate and scheduled), *Resync* and *Simulate*. In the Job & Automation Monitoring app they are grouped by system name and job type. You have the option to drill down from a specific row to the list of executed jobs.

For more information, see Job & Automation Monitoring and the relevant section on the SAP Support Portal.

Getting Support

In case you encounter problems with setting up or using the apps, create a case under the relevant component:

App Name	Component
Configuration & Security Analysis	`SV-CLM-OP-CSA`
Job and Automation Monitoring	`SV-CLM-OP-JM`

Related Information

SAP Cloud ALM

1.12.9 Manage Provisioning Job Logs

After you view and analyze the provisioning job logs, you can download or delete them.

Prerequisites

- You have enabled and set up a source and a target system in the Identity Provisioning UI. Make sure all mandatory properties are configured correctly. See: Enable and Disable Systems [page 2419]
- You have run a provisioning job. See: Start and Stop Provisioning Jobs [page 2472]

Download Execution Logs for All Jobs

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. From the upper right corner, choose the *Download Execution Logs for All Jobs* button.
3. Choose *Download*. If the number of logs is too large, the execution logs will be downloaded in parts. Each part (a ZIP archive) contains 3000 logs, by default.
4. Save all ZIP files in your local file system.

Download All Error Logs for a Single Job

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. Select a job that has finished with error.
3. Above the **Failed Entities** table, choose the button and select *Download All Error Logs for This Job*.
4. Choose *Download*. The job log is downloaded as a ZIP archive. Its name pattern is: **ips_jobErrorLogs_<job ID>_<date>_<time>**
   Hint: The job ID is at the end of the URL of the selected job in the Identity Provisioning admin console.
5. Save the ZIP file in your local file system, and then open it to view the log records of all failed entities from this job.

> **Note**
>
> If your provisioning job is in *Pending Restart* status (that is, temporary paused due to external reasons), the logs for this job will be generated after it is resumed and completed. Be aware that logs for created, skipped, deleted, and failed entities, on the page where the job was paused, will be duplicated, assuming the page size property is configured for the given provisioning system. For more information, see List of Properties [page 80].
>
> For example, if you have set `concur.page.size`=30 and your job paused while processing the 20th entity on the second page, the logs for those 20 entities will be duplicated. The number of duplicated

logs can be equal to or less than the configured page size. If page size is not configured, the default value of 100 will be used.

Download All Skipped Entity Logs for a Single Job

> **Note**
>
> This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

Prerequisites

- You have set the `ips.trace.skipped.entity` property to **`true`** in the source system.
- You have set the `ips.trace.skipped.entity.content` property to **`true`** in the source system.

For more information, see List of Properties [page 80]

Download the skipped entities for a single job to identify the entities themselves, the systems they are skipped from, the reason behind this, as well as to view the content of the entities.

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. Select a job that has at least one skipped entity.
3. On the right-hand side of the *Statistics* section, choose the button and select *Download All Skipped Entity Logs for This Job*.
   The log is downloaded as a `zip` archive. The name of the file follows the pattern: `ips_jobSkippedEntitiesLogs_<job ID>_<date>_<time>`.
4. Save the `zip` file in your local file system, and then open it to view the log records of all skipped entities for this job.
   The log displays the following information:

Entity Details	Value
User	The ID of the skipped entity For example: **`12345678-1a2b-1bc2-3cd4-1234567890ef`**
Group	
System	The system the entity is skipped from. This could be either a source system or a target system. For example: **`IAS.target`**

Entity Details	Value
Skip Reason	The reason the entity is skipped Normally, a user or a group is skipped because it does not fulfill a condition in the source read transformation or the target write transformation. If this is the case, you will see the exact condition the entity does not fulfill. For example: **Code Syntax** `The condition: ($.emails EMPTY false) && ($.userName EMPTY false), is not fulfilled.` A user or a group can also be skipped if you use the `skipOperations` expression in the transformations to avoid creating, deleting, or updating entities in target systems. If this is the case, you will see the following message: `Operation [<create><update><delete>] is skipped in target transformation`
Content	The content (attributes of the skipped entity For example: **Code Syntax** `{"active":true,"displayName":"John Smith","emails":[{"value":"john.smith@example.com"}],"name":{"familyName":"Smith","givenName":"John"},"schemas":["urn:ietf:params:scim:schemas:core:2.0:User","urn:ietf:params:scim:schemas:extension:sap:2.0:User"],"urn:ietf:params:scim:schemas:extension:sap:2.0:User":{"userUuid":"0036024b-0ede-4fc3-9ed7-c55632de8246"},"urn:sap:cloud:scim:schemas:extension:custom:2.0:User":{"userId":"12345678-1a2b-1bc2-3cd4-1234567890ef"},"userName":"","userType":"public"}`

The log is organized in sections which start with the ID of the skipped entity. If a user or a group is skipped in more than one systems, the log will display the ID of the skipped entity as many times as there are systems where the entity is skipped from, the skip reason and the entity's content.

Download All Created Entity Logs for a Single Job

> **Note**
>
> This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

Prerequisites

- You have set the `ips.trace.created.entity` property to **`true`** in the source system.
- You have set the `ips.trace.created.entity.content` property to **`true`** in the source system.

For more information, see List of Properties [page 80]

Download the created entities for a single job to identify the system in which they are created and to view the content of the entities.

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. In the *Job Execution Logs* screen, search for a job log and select it.
3. If the job has created at least one entity, you are able to choose the button on the right-hand side of the *Statistics* section and select *Download All Created Entity Logs for This Job*.
   The log is downloaded as a `zip` archive. The name of the file follows the pattern: `ips_jobCreatedEntitiesLogs_<job ID>_<date>_<time>`.
4. Save the `zip` file in your local file system, and then open it to view the log records of all created entities for this job.
   The log displays the following information:

Entity Details	Value
User	The ID of the created entity in the target or proxy system For example: **`12345678-1a2b-1bc2-3cd4-1234567890ef`**
Group	
System	The system in which the entity is created. This could be either a target system or a proxy system. For example: **`IAS.target`**

Entity Details	Value
Content	The content attributes of the created entity For example: Code Syntax `{"active":true,"displayName":"John Smith","emails":[{"value":"john.smith@example.com"}],"name":{"familyName":"Smith","givenName":"John"},"schemas":["urn:ietf:params:scim:schemas:core:2.0:User","urn:ietf:params:scim:schemas:extension:sap:2.0:User"],"urn:ietf:params:scim:schemas:extension:sap:2.0:User":{"userUuid":"0036024b-0ede-4fc3-9ed7-c55632de8246"},"urn:sap:cloud:scim:schemas:extension:custom:2.0:User":{"userId":"12345678-1a2b-1bc2-3cd4-1234567890ef"},"userName":"","userType":"public"}`

The log is organized in sections which start with the ID of the created entity. If a user or a group is created in more than one systems, the log will display the ID of the created entity as many times as the number of systems in which it is created and the entity's content.

Download All Updated Entity Logs for a Single Job

> **Note**
>
> This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

Prerequisites

- You have set the `ips.trace.updated.entity` property to **`true`** in the source system.
- You have set the `ips.trace.updated.entity.content` property to **`true`** in the source system.

For more information, see List of Properties [page 80]

Download the updated entities for a single job to identify the system in which they are updated and to view the content of the entities.

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.

2. In the *Job Execution Logs* screen, search for a job log and select it.
3. If the job has updated at least one entity, you are able to choose the button on the right-hand side of the *Statistics* section and select *Download All Updated Entity Logs for This Job*.
   The log is downloaded as a `zip` archive. The name of the file follows the pattern: `ips_jobUpdatedEntitiesLogs_<job ID>_<date>_<time>`.
4. Save the `zip` file in your local file system, and then open it to view the log records of all updated entities for this job.
   The log displays the following information:

Entity Details	Value
User *Group*	The ID of the updated entity in the target or proxy system For example: **`12345678-1a2b-1bc2-3cd4-1234567890ef`**
System	The system in which the entity is updated. This could be either a target system or a proxy system. For example: **`IAS.target`**

Content	The content attributes of the updated entity
	For example:
	Code Syntax
	`{"active":true,"displayName":"John Smith","emails":[{"value":"john.smith@example.com"}],`
	`"name":{"familyName":"Smith","givenName":"John"},"schemas":["urn:ietf:params:scim:schemas:core:2.0:User","urn:ietf:params:scim:schemas:extension:sap:2.0:User"],"urn:ietf:params:scim:schemas:extension:sap:2.0:User":{"userUuid":"0036024b-0ede-4fc3-9ed7-c55632de8246"},"urn:sap:cloud:scim:schemas:extension:custom:2.0:User":{"userId":"12345678-1a2b-1bc2-3cd4-1234567890ef"},"userName":"","userType":"public"}`

The log is organized in sections which start with the ID of the updated entity. If a user or a group is updated in more than one systems, the log will display the ID of the updated entity as many times as the number of systems in which it is updated and the entity's content.

Download All Deleted Entity Logs for a Single Job

> **Note**
>
> This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

Prerequisites

You have set the `ips.trace.deleted.entity` property to **`true`** in the source system.

For more information, see List of Properties [page 80]

Download the deleted entities for a single job to identify the system from which they are deleted.

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. In the *Job Execution Logs* screen, search for a job log and select it.
3. If the job has deleted at least one entity, you are able to choose the button on the right-hand side of the *Statistics* section and select *Download All Deleted Entity Logs for This Job*.
   The log is downloaded as a `zip` archive. The name of the file follows the pattern: `ips_jobDeletedEntitiesLogs_<job ID>_<date>_<time>`.
4. Save the `zip` file in your local file system, and then open it to view the log records of all deleted entities for this job.
   The log displays the following information:

Entity Details	Value
User *Group*	The ID of the deleted entity in the target or proxy system For example: **`12345678-1a2b-1bc2-3cd4-1234567890ef`**
System	The system from which the entity is deleted. This could be either a target system or a proxy system. For example: **`IAS.target`**

   The log is organized in sections which start with the ID of the deleted entity. If a user or a group is deleted from more than one systems, the log will display the ID of the deleted entity as many times as the number of systems from which it is deleted.

Download Job Logs via API

> **Note**
>
> This functionality is available only for Identity Provisioning bundle and standalone tenants running on SAP Cloud Identity infrastructure.

- You need a technical user (a user of type System in SAP Cloud Identity Services admin console) with *Access Identity Provisioning Tenant Admin API* permission assigned. For more information, see Managing Administrators.

Use the Identity Provisioning tenant admin API to download job logs via API calls for a single provisioning job. The API is available on the SAP Business Accelerator Hub: SAP Cloud Identity Services *Identity Provisioning Service* > *API Reference* > *JobLogs*. The URL for accessing the Tenant Admin API follows the pattern: `https://<ias-tenant-host>/ips/service/publicapi/v1/jobLogs/<JobId>?action=export&logType=<logType>`, where:

Parameter	Value
`<JobId>`	The job identifier
Action	The action to be executed Only possible value: **`export`**
`<logType>`	The type of the job log to be downloaded Possible values: • **`commonLog`** - Download logs containing the following details for this specific job execution (start time, end time, statistics, type, mode). These details are currently included in the common logs for all job executions. • **`failedEntitiesLog`** - Download logs containing details about the failed entities for this specific job execution. • **`skippedEntitiesLog`** - Download logs containing details about the skipped entities for this specific job execution. • **`createdEntitiesLog`** - Download logs containing details about the created entities for this specific job execution. • **`updatedEntitiesLog`** - Download logs containing details about the updated entities for this specific job execution. • **`deletedEntitiesLog`** - Download logs containing details about the deleted entities for this specific job execution.

For example: `https: //<ias-tenant-host>/ips/service/publicapi/v1/jobLogs/cbc1eb01686664856111?action=export&logType=allErrorsLog`

Save the `zip` file in your local file system, and then open it to view the log records for the log type you have defined.

Delete Job Logs

If you don't need your job logs anymore, you can delete them. You can do this manually or automatically (by setting a retention period).

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Provisioning Logs* > *Job Logs*.
2. Choose the *Delete Logs* icon.

   > ⚠ Caution
   >
   > This deletes the logs for all finished jobs. If a job is still running though, it will stay along with its logs.

3. You can set a time period for keeping the job logs available for monitoring.
   1. From the upper right corner, choose *Configure Job Logs Settings*.
   2. Set a period (**7**, **14** or **30** days). Logs which are older than this period will be automatically deleted. By default, job logs are kept for 7 days.
   3. If you want to keep the logs longer, you can download and save them in your local file system.

1.12.10 Manage Job Notifications

You can subscribe to a source system to receive notification e-mails. They provide information about the job execution and links to download job logs, in case of created, updated, failed, skipped, or deleted entities.

Context

When you subscribe to a source system, you can receive notification e-mails in the following cases:

- You start or schedule a provisioning job and it fails.
  You'll receive an e-mail with subject *Provisioning Running with Error. Source System: <name>*. You receive one e-mail per job, after the first failed entity. If more entities fail during this job, no additional e-mails will be sent. This behavior is related to property `ips.job.notification.skip.intermediate.notifications`.
- The failed job has finished.
  You'll receive an e-mail with subject *Provisioning Finished with Error. Source System: <name>*. By default, if the same job runs again and keeps failing, no further notifications will be sent to your e-mail. However, you can control the notifications via properties `ips.job.notification.ignored.consecutive.failures` and `ips.job.notification.repeat.on.failure`. For more information, see: List of Properties [page 80]
- The job is back to normal (the problem with the failed entities has been resolved).
  After a new run, the job has successfully finished. You'll receive only one e-mail with subject *Provisioning Success. Source System: <name>*.

The notification e-mail tells you which are the source and the target systems, what are the job type and the read mode, its start time and status. In some cases the e-mail contains job execution specifics that have

influenced the deletion of entities from the target system(s). It includes also the `Navigate to details` link that opens the *Job Execution Details* screen in the Identity Provisioning UI.

In case your job finished with created, updated, failed, skipped, or deleted entities, links to `Download created entities logs`, `Download updated entities logs`, `Download error logs`, `Download skipped entities logs`, and `Download deleted entities logs` are provided, respectively. The content of the downloaded log files depends on your configuration of the `ips.trace.created.entity`, `ips.trace.created.entity.content`, `ips.trace.updated.entity`, `ips.trace.updated.entity.content`, `ips.trace.skipped.entity`, `ips.trace.skipped.entity.content`, `ips.trace.failed.entity.content`, and `ips.trace.deleted.entity` properties. For more information, see: List of Properties [page 80]

> **Note**
>
> Sending navigation links to the download page of created, updated, failed, skipped, and deleted entities is supported for tenants running on SAP Cloud Identity Services infrastructure.

> **Note**
>
> If you subscribe to a source system, and then run a successful provisioning job, no notification e-mails will be sent.

Procedure

1. Sign in to the administration console of SAP Cloud Identity Services and navigate to *Identity Provisioning* > *Source Systems*.
2. Select the system you need to watch and choose *Jobs*.

   > **Note**
   >
   > Notifications are supported only for read and resync jobs.

3. Choose *Subscribe*.
   - To subscribe yourself, choose *Subscribe me*.
   - To subscribe another user or a group (distribution list), choose *Subscribe others*. Fill in the required fields and choose *Add*.

     > **Note**
     >
     > From the *Recipients* list, you can remove existing subscribers. To do that, go to the *Action* column and choose the icon.

4. You can now run or schedule a provisioning job.
5. If you no longer need to be subscribed to a source system, choose *Subscribe* > *Unsubscribe me*.

Related Information

Monitor Provisioning Job Logs [page 2982]

1.12.11 View Troubleshooting Logs

Tenant administrator can filter and view troubleshooting logs directly in the administration console for SAP Cloud Identity Services to diagnose problems with authentication.

Context

> → Tip
>
> Use the audit logs option to track changes in the personal data.

The maximum number of log entries is 1000. The search criteria you can choose include:

Criteria	Notes
Time period	The time period is in Coordinated Universal Time (UTC). • You have one hour time period for searching logs. • The date is limited back to 14 days from the current date **Note** The default selection is the current date, with a start period - one hour back from your current time in UTC. **→ Remember** The start and end periods can't be later than the current UTC time. The end period can't also be earlier than the start period. The search period can't exceed 60 minutes.
Severity	• All - default • Error • Info • Warning

Once you have the results you can filter them by *Time*, *Severity*, *IP Address*, *CorrelationID*, or *Message.*

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose *Monitoring & Reporting* > *Troubleshooting Logs*.
3. Define the criteria and start your search.
4. **Optional:** Export the troubleshooting logs in an Excel file.

Next Steps

- View information about the JWT payload of the OpenID Connect tokens issued or received by Identity Authentication. For more information, see Logging OpenID Connect (OIDC) Tokens [page 2980]

Related Information

Audit Logs [page 2966]

1.12.12 Download Troubleshooting Logs

Tenant administrator can view Identity Authentication troubleshooting logs to monitor the system, and diagnose and solve problems.

Context

The maximum number of log entries is 10000. The criteria you can choose include:

Criteria	Notes
Time period	• 1 hour - default • 4 hours • 24 hours
Severity	• All • Error - default • Info • Warning

Criteria	Notes
File format	• JSON • XML • CSV - default

Procedure

1. Sign in to the administration console for SAP Cloud Identity Services.
2. Choose *Monitoring & Reporting* > *Troubleshooting Logs*.
3. Choose the *Download* button.
4. Define your criteria and download the log entries.

Next Steps

- Use the Support Log Assistant 2.0 tool to analyze your troubleshooting logs. For more information, see Analyze Troubleshooting Logs with Support Log Assistant 2.0 [page 3022].
- View information about the JWT payload of the OpenID Connect tokens issued or received by Identity Authentication. For more information, see Logging OpenID Connect (OIDC) Tokens [page 2980]

1.12.13 Analyze Troubleshooting Logs with Support Log Assistant 2.0

Context

The Support Log Assistant 2.0 is a tool that allows you to automatically scan and analyze text files such as logs, configuration files, or traces. The tool then suggests solutions to known issues found in the files and highlights important details that it finds. The tool is integrated into the incident logging procedure and is also available as a standalone tool.

Procedure

1. Access the tool via the following link: Support Log Assistant 2.0.
2. Choose *Add Files*, and select the files that you want to analyze.

No files are uploaded to SAP during this entire process. Your files are analyzed locally within your browser.

Once the log files have been selected, they are scanned to identify what type of log file they are. The files that are identified are listed on the top. Under them are the files that can't be identified and scanned.

3. Choose *Scan Files*, and select the *ALERTS*, *FILES*, or *ADDITIONAL DETAILS* tab.
4. Choose *Summary* to see a short summary of the issues found and their solutions.

Next Steps

If you haven't found a solution, you can choose the *Contact SAP Support* link to access other ways to receive support with your issue.

1.12.14 Troubleshooting Issues with Authentication and User and Group Management

While using the Identity Authentication service, you encounter issues or have questions regarding specific settings, limitations, or other aspects.

If you experience issues when using Identity Authentication service, check the following topics for help.

General: What information to include in a support ticket

You can report an incident on SAP Support Portal Home with the `BC-IAM-IDS` component for issues related to authentication and user and group management.

Please include the following information:

- - Your tenant ID from `https://tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin`
  - Your email address
  - The error message you see
  - Attachments of screenshot that show the reproduced error, including the exact timestamp
  - If you solved your issue, a description of the steps you took
  - List of Knowledge Base Articles (KBAs) and SAP Notes, you have used to solve the issue
  - Attachments of SAML traces as per KBA: 2461862 - Collecting SAML traces with Chrome or Firefox

Custom Domains [page 3069]
Problems that you may face when using custom domains in Identity Authentication.

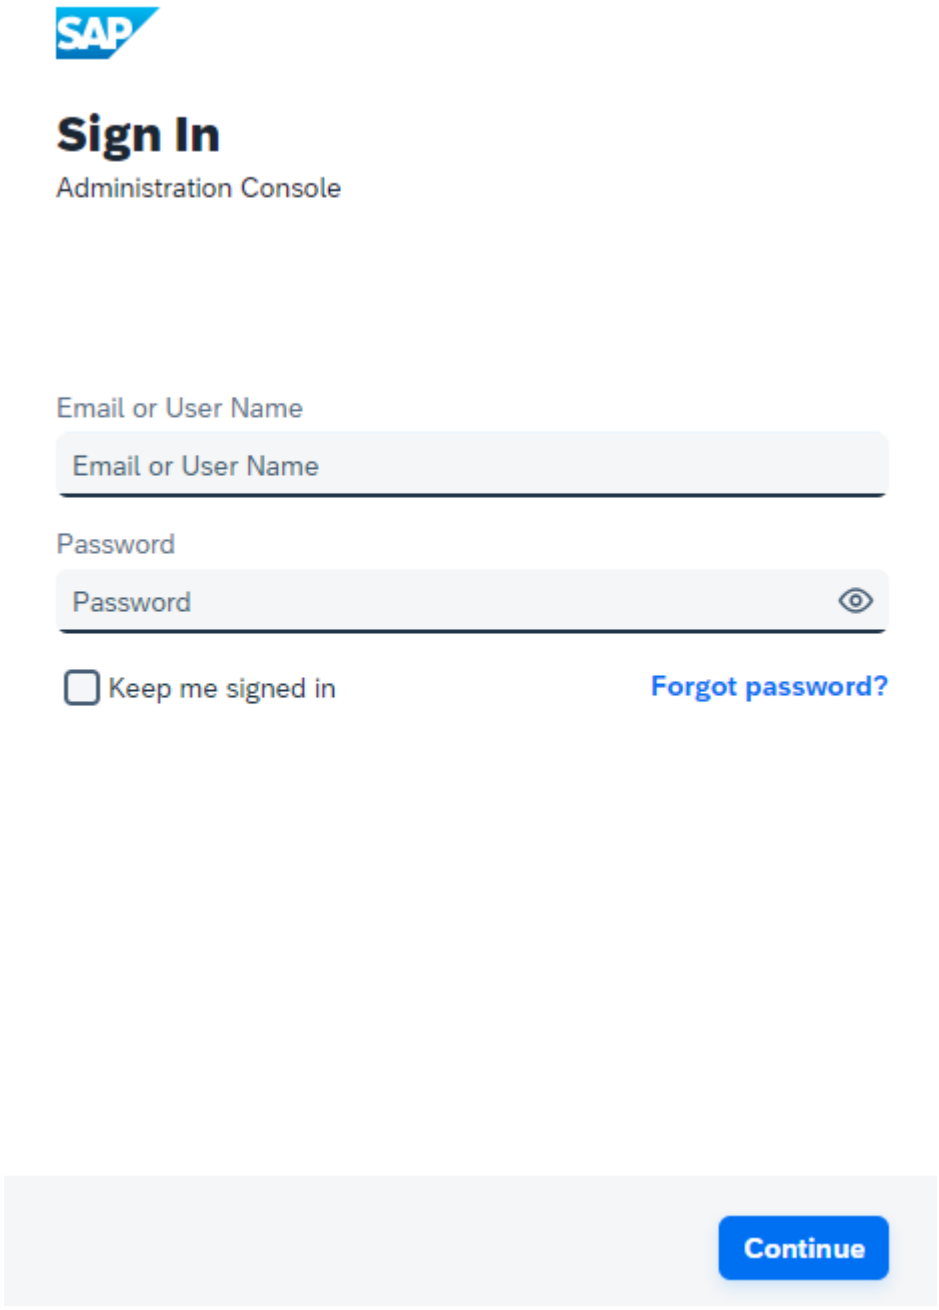
1.12.14.1 Accessing the Administration Console

Problems with the signing into the administration console for SAP Cloud Identity Services.

You can reach the tenant administration console via the URL `https://<tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin` pattern. For more information, see Application Types [page 63].

You must be an administrator user.

The Sign In screen appears correctly



but you face one of the following problems:

I don't know who the tenant administrator is

Symptom:

You don't know who the tenant administrator is

Solution:

Contact an existing administrator for the tenant.

Cloud Identity Services doesn't use for authentication the users registered in the SAP Service Marketplace, but maintains an own user store for administrators and users.

Once you purchase a customer or partner account in SAP BTP, a user account for Cloud Identity Services is created for the contact person specified in the *Order Form*. The contact person is the first tenant administrator in the administration console for Cloud Identity Services. That person receives an activation email for the administration console account. The subject of the email is: **Activate Your Account for Identity Authentication Service**. The first administrator activates the account and continues to the administration console for Identity Authentication via the console's URL.

The first administrator can add new tenant administrators.

See also:

- KBA 3035908 - How to Find the Identity Authentication / Identity Provisioning Tenant Administrator Information or Tenant URL?
- Identity Authentication Service tenant specific request only possible for customer owning the tenant
- Access Admin Console [page 542]
- Reset Your Forgotten Password [page 2777]
- Activate Your Account [page 540]
- Access Admin Console [page 542]
- Manage Administrators [page 543]

I can't sign in to admin console of custom tenant with S-user

Symptom:

Logging into the administration console of a Cloud Identity services tenant with an S-user is unsuccessful.

Solution:

See KBA **2424064** - Cannot login to Administration Console of custom Identity Authentication tenant with S-user.

Administration Console isn't accessible due to network problem

Symptom:

The administration console can't be accessed, the browser returns `ERR_EMPTY_RESPONSE`, or similar error message `ERR_TIMED_OUT`, `took too long to respond`, and so on.

Timeout-related errors can also be seen on the browser.

Solution:

See KBA 2918278 - Identity Authentication tenant is not accessible due to network problem.

Email activation problem

As a tenant administrator you can reach the administration console via the URL https://<tenant ID>.accounts.ondemand.com/admin or https://<tenant ID>.accounts.cloud.sap/admin pattern.

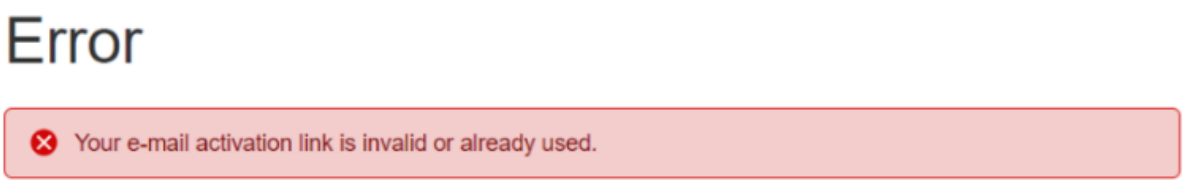
`Tenant ID` is an automatically generated ID by the system. The URL is in the activation e-mail received by you.

Check your inbox for an e-mail from **ias@notifications.sap.com** or **notification@sapnetworkmail.com**.

See also: Activate Your Account [page 540].

I have activated my account but I still face problems

You see the following error after you've chosen the activation email link:



This message means that the user or someone else clicked the activation link after it had already expired or the user account at the Identity Authentication tenant had already been activated.

Use the "Forgot Password" functionality to gain access to your tenant. For more information, see Reset Your Forgotten Password [page 2777].

I haven't activated my account or didn't receive any email

Open your inbox and search for an email from **ias@notifications.sap.com** or *notification@sapnetworkmail.com*. The email contains the URL to activate your account.

- **If the URL is expired**
  - The system sends you a new activation e-mail. Follow the procedure to activate your account.
- **If the link is invalid or already used, or you haven't received an email**
  - Check your spam folder
  - Contact an existing administrator for the tenant to ask the following
    - Whether an activation email was sent (or if only an initial password was set, since in this case no email is sent).
    - To resend the activation email (*Admin Console* > *User Management* > *select the user* > *Authentication* > *Password Details* > *Password Details* > *Send Email*. See also Send Reset Password Email [page 2381].

See also: **KBA 2517844** - How to get the activation e-mail of an Identity Authentication tenant.

Error "Sorry, we could not authenticate you. Try again."

This is a general error, and it can be a symptom of many different situations. You try to sign in...:

... after an LDAP user store is configured.

Symptom:

The user is locked when configuring the LDAP user store on SAP BTP.

Solution:

You have configured an LDAP scenario based on the Configure SAP BTP When Connecting to an LDAP User Store documentation. However, when you attempt to sign in, you see **"Sorry, we could not authenticate you. Try again."**

There is an issue in the connection between the SAP Cloud Connector and the corporate user store due to an issue with the system user which is used to access the corporate user store.

See KBA: 2680867 - Check if the system user is locked when configuring and LDAP user store on SAP BTP

... with S-user credentials

Symptom:

You're trying, without success, to sign in to the administration console as an S-user.

Solution:

There are no S-users used in custom tenants. S-users can only log on to `accounts.sap.com`, which belongs to SAP. In a custom tenant, you can sign in using your email address and password.

See KBA 2424064 - Cannot login to admin console of custom Identity Authentication tenant with S-user

... but sign-in fails after successful activation with error: Sorry, we could not authenticate you. Try again.

Symptom:

The user sign-in fails after the activation link is called and the password update was successful.

The user receives the following message:

Sorry, we could not authenticate you. Try again.

In the Troubleshooting log, the following error is displayed:

Identity Provider could not process the authentication request received due to error on its own side. The SP user [<user_uuid>] is with status inactive for Service Provider [<service_provider_url>] Caused by: javax.security.auth.login.AccountException: The SP user [<user_uuid>] is with status inactive for Service Provider [<service_provider_url>] Caused by: The SP user [<user_uuid>] is with status inactive for Service Provider [<service_provider_url>]

Solution:

See KBA 2770797 - The IAS tenant user login fails after successful activation: Sorry, we could not authenticate you. Try again.

but ... you forgot your password

Use the "Forgot Password" functionality to gain access to your tenant. For more information, see Reset Your Forgotten Password [page 2777].

If you have an account as administrator in Cloud Identity Services, an email with a link to a page where you can reset your password is sent. Note that the email might take a few minutes to reach your inbox. If you don't have an account as administrator, you won't receive an e-mail. In this case, contact an existing administrator for the tenant.

See also KBA 2517844 - How to get the activation e-mail of an Identity Authentication tenant.

... but you aren't an administrator

Cloud Identity Services does not use for authentication the users registered in the SAP Service Marketplace, but maintains an own user store for administrators and users. Only administrators can access the administration console.

Ask an existing administrator to add new tenant administrators. See Manage Administrators [page 543] and 2570572 - How to add Administrators to Identity Authentication tenants.

... but you receive error Used logon identifier is not allowed

Symptom

Sign in to the administration console for Cloud Identity services is failing with error: **Sorry, we could not authenticate you. Try again.**. Using the forgot password link allows you to reset the password and log in. However, signing out and trying to sign in again the same error is shown as previously. Only a password reset allows login again for just one user session.

The Troubleshooting log shows the following error:

User authentication failed. Reason: Used logon identifier isn't allowed; Identifier: [<logon_identifier>]

Solution:

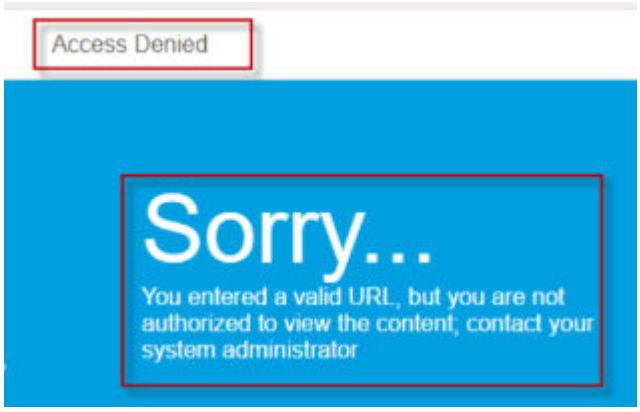
See KBA 2895349 - Cannot logon to Identity Authentication Administration Console with valid logon identifier and password.

Error "Access denied. Sorry... You entered a valid URL, but you are not authorized to view the content."

Symptom

Immediately after you've signed in to the administration console for Cloud Identity Services, you see the message:

Access Denied. Sorry... You entered a valid URL, but you are not authorized to view the content, contact your system administrator

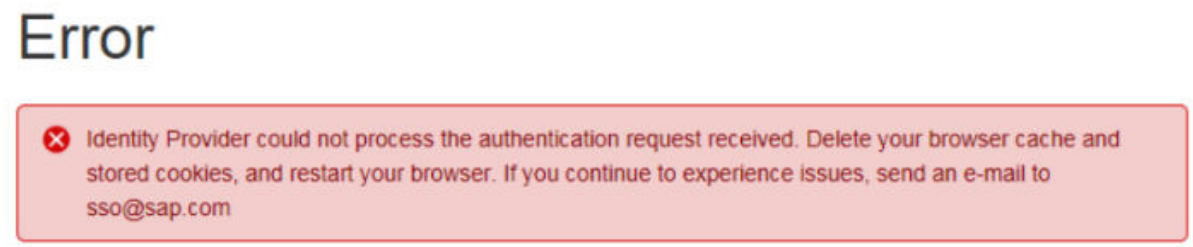


Ask an administrator to configure the required authorization, as explained in the following KBA:

2579343 - Accessing /admin of custom Identity Authentication tenant ends with "you are not authorized to view the content"

Error "The identity provider could not process the authentication request received"

Cloud Identity Services using the Security Assertion Markup Language (SAML) 2.0 as identity provider (IdP) fails to process the authentication request.



Make sure the service provider's name is the same as configured in Cloud Identity Services, acting as IdP:

2260000 - Identity provider could not process the authentication request received.

If this doesn't solve your problem please open a ticket on BC-IAM-IDS component, and provide the following information:

- Your tenant ID from `https://tenant ID>.accounts.ondemand.com/admin`
- Your email address
- The error message that you see
- Attachments of screenshot that show the reproduced error, including the exact timestamp
- If you solved your issue, a description of the steps you took
- List of KBAs and SAP Notes, you have used to solve the issue
- Attachments of SAML traces as per KBA: 2461862 - Collecting SAML traces with Chrome or Firefox

Error "Access to this Identity Authentication tenant is blocked, please contact your administrator"

Symptom:

Accessing the SAP Cloud Platform Identity Authentication Service (IAS) tenant fails with the following error:

"HTTP Status 403 – Access to this Identity Authentication tenant is blocked, please contact your administrator."

Solution:

See **KBA** - https://launchpad.support.sap.com/#/notes/2909142

1.12.14.2 User Import

Problems with the user import in the administration console for SAP Cloud Identity Services.

As a tenant administrator, you can import new users or update existing ones for a specific application with a CSV file via the administration console. You can also send activation emails to the users that haven't received activation emails for that application so far.

The scenario, requirements, and configurations are described in Import or Update Users for a Specific Application.

> → Tip
>
> You as a tenant administrator can view Identity Authentication troubleshooting logs to monitor the system, and diagnose and solve problems. For more information, see View Troubleshooting Logs and Analyze

> Troubleshooting Logs with Support Log Assistant 2.0. See also **KBA 2942816** - How to export and self-analyze Troubleshooting logs from Identity Authentication Service.

You may face one of the following problems:

Users don't receive emails from `notification@sapnetworkmail.com` or `ias@notifications.sap.com` after a CSV user import

Symptom:

You import users by uploading a CSV file successfully, but users don't receive email for that.

Solution:

See KBA 2940801 - E-mail is not received after "Import Users"

Email sending is interrupted

Symptom:

There is a need to import users to an application and to send the initial emails, but the second step fails with the following message:

"First 0 mails are sent. Mailing has been interrupted because sending e-mail to user with e-mail address <email> is not possible. Please update the user e-mail and trigger e-mail sending again."

Solution:

See KBA 2833007 - First 0 mails are sent.

Users have to be redirected to a specific URL after successful registration

Symptom:

There is a need to redirect users to a specific URL after a successful registration.

Solution:

See **KBA 2942954** - Redirect users after successful registration in Identity Authentication

Import users to Identity Authentication with additional attributes

Symptom:

You have to import user data into Identity Authentication using the *Import Users* option of the administration console, but it only supports some certain attributes of a user, not all.

All supported attributes of a user for this function are mentioned in the SAP Help Document: Import or Update Users for a Specific Application.

Solution:

SAP provides SCIM REST API which allows to set all other user attributes in a programmatic way.

See SCIM REST API and **KBA 2533357** -Import users to Identity Authentication with additional attributes

Alternatively, SAP provides SCIM REST API which allows to set all other user attributes in a programmatic way.

You receive error: "Provided file has the wrong type"

Symptom:

When importing users to Identity Authentication, the import fails with the following error:

"Provided file has the wrong type. Please specify a different file and try again."

Solution:

See **KBA 2461975** - Import users fails with error: Provided file has the wrong type

You receive error: "User with email '' contains empty values - error during user import"

Symptom:

You see the following error at user import in the Identity Authentication service:

"User with email '' contains empty values."

Solution:

See **KBA 2859442** - User with email '' contains empty values - error during user import

You receive error: "User import has been interrupted for users with email address "<email_address>".

Symptom:

During user import (update), the following error is shown when the user already exists in the userbase:

User import has been interrupted for users with e-mail address "<email_address>".

The reason for this error is as follows: **"The import reported error".**

Solution:

See KBA 2958785 - Identity Authentication Import Users throws Attribute '<attributeName>' has wrong format error

You receive error: "Home URL or SAML 2.0 configuration of the application missing. You can only import users, but you cannot send activation emails."

Symptom:

You have imported users into the Identity Authentication tenant, but the activation e-mails to them can't be sent. The following message is shown:

"Home URL or SAML 2.0 configuration of the application missing. You can only import users, but you cannot send activation emails."

Solution:

See **KBA 2591826 -** Activation e-mails cannot be sent - Home URL or SAML 2.0 configuration of the application missing

You receive error: "The CSV file failed to upload..."

Symptom:

You, as an administrator, imported a CSV user file in Identity Authentication and it returns the following error:

"The CSV file failed to upload. Contact your system administrator for assistance."

Solution:

See **KBA 2975595** - Import users CSV file in IAS fails with error - The CSV file failed to upload.

You receive error: "0 emails sent when trying to send activation e-mails on Identity Authentication"

Symptom:

Users are imported to Identity Authentication, but when choosing "Send Emails", a message is received, stating that **"0 emails sent when trying to send activation e-mails on Identity Authentication".**

Solution:

See **KBA 2471540** - 0 emails sent when trying to send activation e-mails on Identity Authentication

You receive error: "First 0 users are imported. User import has been interrupted for users with email address . The reason for this error is as follows: "The import reported error".

Symptom

Importing users from a CSV file in Identity Authentication Service is failing with the following error message:

First 0 users are imported. User import has been interrupted for users with e-mail address <user e-mail>. The reason for this error is as follows: "The import reported error".

Solution:

See **KBA 2717186** - "User import has been interrupted" in Identity Authentication Service

You receive error: "First <number> users are imported. User import has been interrupted due to an invalid entity."

Symptom:

The first users in the CSV file are already imported for the tenant. The next user was not imported because the CSV file contains an incorrect data for that user.

Solution:

Delete the first <number> users from the CSV file, correct the invalid row, and re-import the updated file.

You receive error: "First <number> users are imported. User import has been interrupted for user with email address ."

Symptom:

The first <number> users in the CSV file are already imported for the tenant. The next user was not imported because its data in the CSV file conflicts with the data in the database.

Solution:

- Correct the email for the logon name under the mail column, delete the first <number> users from the CSV file, and re-import the updated file.

  > ⚠ Caution
  >
  > During CSV import, you can't change the email of an existing user.

- Change the user logon name because the same logon name is used for another user in the database, delete the first <number> users from the CSV file, and re-import the updated file.

  > ⓘ Note
  >
  > You can't have two users with the same logon name, but with different emails.

- Contact a tenant administrator of Identity Authentication.

You receive error: "First <number> users are imported. User import has been interrupted due to multiple users in the database with the same email address <email address>. The email address must be unique for each user."

Symptom:

The first <number> users in the CSV file are already imported for the tenant. The next user was not imported because its email matches with the email of other users.

Solution:

- Correct the user data, delete the first number> users from the CSV file, and re-import the updated file.
- Contact an operator of Identity Authentication to check if your emails exist in the database.

You receive error: "The imported CSV file contains entries with a duplicate email <email address>. The values under mail column must be unique."

Symptom:

You have provided a CSV file with a `mail` column that has the same email entries.

Solution:

Correct the file so that the mail column contains unique values.

You receive error: "The imported CSV file contains entries with a duplicate login name <login name>. The values under loginName column must be unique."

Reason:

You have provided a CSV file with a `loginName` column that has the same entries.

Solution:

Correct the file so that the `loginName` column contains unique values.

You receive error: "The imported CSV file does not contain one of the mandatory columns: status, mail and lastName. Make sure that the columns status, mail, lastName are in the CSV file."

Symptom

An administrator imports the CSV user file in Identity Authentication and it returns the following error:

The imported CSV file does not contain one of the mandatory columns: status, mail and lastName.

Make sure that the columns `status`, `mail`, `lastName` are in the CSV file.

Solution:

Follow the "Import or Update Users for a Specific Application" documentation document which explains the pre-requisites, possible columns with the attributes, mandatory columns, possible values for columns.

Follow the example in the documentation which shows you how your CSV file should look like.

See also KBA 2607696 - Import users CSV file in Cloud Identity Authentication Service and it fails with error

1.12.14.3 Emails

Problems with emails sent for the different application processes.

Check the following entries for issues with emails sent for the different application processes:

Email Activation

You have received an email from **notification@sapnetworkmail.com** or:

- If you have already activated your account - You see the following error "E-Mail Already Activated" after you've clicked the activation email link." E-Mail Already Activated. This message means that the Cloud Identity Services has already been activated. Use the "Forgot Password" option to gain access to your tenant.
- If you haven't activated your account or didn't receive an email - Open your mail box and search for an e-mail from **ias@notifications.sap.com** or **notification@sapnetworkmail.com**. The email contains a link to activate your account. The following is possible:
  - The link has expired - The system sends you a new activation email. Follow the procedure to activate your account.
  - The link is invalid or already used, or you haven't received an email:
    - Check your spam folder
    - Contact an existing tenant administrator for the tenant to ask the following.
      - Whether an activation email was sent (or if only an initial password was set, since this case no email is sent).
      - To resend the activation email.

      > **Note**
      >
      > Who is my tenant administrator?

See also: **KBA 2517844** - How to get the activation e-mail of an Identity Authentication tenant

Check if emails are sent

Symptom:

End-users state that they don't receive emails from Identity Authentication for various application processes such as account activation, password reset, and so on.

Solution:

There is a need to troubleshoot if the e-mails are sent from Identity Authentication to determine if the issue is with Identity Authentication or the email server.

See **KBA 2978346** - How to check if e-mails are sent and the sender from Identity Authentication Service.

Error: "Internal error; contact system administrator" in Identity Authentication

Symptom:

An email template in the *Default* template of an application is uploaded. During the attempt to manually send it, the following pop-up warning is shown:

"Internal error; contact system administrator"

In the browser logs, the following error is visible:

"500 Internal Server Error"

Solution:

See **KBA 2573314** - E-mail template error: Internal error; contact system administrator in Identity Authentication (IAS)

Emails are in English language, which isn't the desired language

Symptom:

Activate Your Account or *Password Reset* email is in English, which isn't the desired language.

Solution:

See **KBA 3023020** - "Password Reset" e-mail is in English

User receives error: "Your e-mail activation link is invalid or already used"

Symptom:

Account activation of the Identity Authentication service isn't possible. The following error is displayed:

"Your e-mail activation link is invalid or already used."

Solution:

See **KBA 2637748** - Identity Authentication - Your email activation link is invalid or already used

Identity Authentication didn't send Forgot Password email

Symptom:

After requesting a new password with the *Forgot Password* option, the email isn't received.

The troubleshooting log (see **KBA 2942816** - How to export and self-analyze Troubleshooting logs from Identity Authentication Service) is showing the following error message:

"No Forgot password message sent to <e-mail address>. Limit exceeded!"

Solution:

Solution KBA 2981630 - No Forgot password message sent from Identity Authentication

Emails sent still contain the SAP logo

Symptom:

After you have configured the email templates in the administration console for Identity Authentication, the emails sent still contain the SAP logo.

Solution:

See **KBA 2854429** - How to Set Custom Company Logo for IAS Template E-mails

Email template set in Identity Authentication tenant isn't working

Symptom:

An email template set within the Identity Authentication tenant has been configured but the templates aren't applied when testing them.

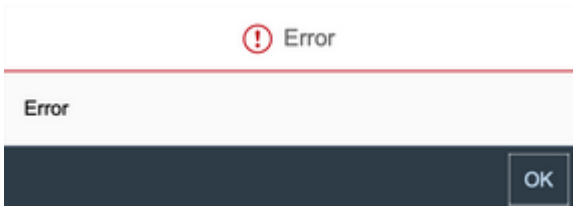
Solution:

See **KBA 2675079** - E-mail template set in Identity Authentication tenant not working

Error when uploading custom email template sets in Identity Authentication

Symptom:

The following error message is received when uploading custom email template sets in the administration console for Identity Authentication:



Solution:

See **KBA 2716042** - Error when uploading custom E-Mail Template Sets in Identity Authentication.

Changing the email ias@notifications.sap.com or notification@sapnetworkmail.com in Identity Authentication

Symptom:

When a user requests to reset their password in an Identity Authentication tenant, they receive an email from **notification@sapnetworkmail.com** (as of Sep 29, 2021 - **ias@notifications.sap.com**). There is a need to change this e-mail to another sender/server. Identity Authentication also provides the possibility to configure a custom mail server for the application processes e-mails.

Solution:

See **KBA** - Changing the e-mail ias@notifications.sap.com (notification@sapnetworkmail.com) in Identity Authentication.

1.12.14.4 Authentication

Problems with the authentication of the user and administrator.

The following authentication issues may occur:

Error: "Sorry, we could not authenticate you. Try again"

Symptom

When you try to sign in to an SAP Cloud Identity Services tenant, the following error message can be seen: **"Sorry, we could not authenticate you. Try again"**

Solution

See KBA **3291844** - Sorry, we could not authenticate you. Try again" error message seen in Identity Authentication login

Error: "Your domain is not trusted. Please contact your system administrator"

Symptom::

When using embedded frames or overlays in an application that authenticates against the Identity Authentication, the following error is displayed when trying to log in via the domain of the overlay:

"Your domain is not trusted. Please contact your system administrator."

The other error can be related to trusted domains:

"Your request failed because the page you have to be redirected to is not trusted. Please contact your system administrator."

Solution:

See KBA **2739473** - "Your domain is not trusted. Please contact your system administrator" in Identity Authentication Service

Error: "The digital signature of the received SAML2 message is invalid"

Symptom:

Identity Authentication tenant returns the message in subject when an authentication request is done from a specific service provider.

This can be checked via a SAML tracer. For more information, see **KBA** 2461862 - Collecting SAML traces with Chrome or Firefox.

If the service provider is an SAP BTP subaccount, an Error 500 can be seen on the screen.

In the Troubleshooting log, the following error is displayed:

"message=Identity Provider could not process the authentication request received due to error on its own side. An unexpected exception occurred. See call stack for details. Caused by: Signature of the SAML2 protocol token cannot be validated because neither primary nor secondary certificates are available in the configuration"

Solution:

See KBA **2645425** - The digital signature of the received SAML2 message is invalid

Reset Password isn't working

Symptom:

The Reset Password option isn't working for Identity Authentication and in the Troubleshooting Logs you find the following error:

"Identifier xxx@xx.xx not unique"

Solution:

See KBA 3030889 - Reset password for IAS fails: "Identifier xxx@xx.xx not unique"

Attribute with name loginName isn't supported

Symptom:

Authentication through Identity Authentication is failing with the following error message:

"Identity provider cannot process the request because the configuration is incorrect. Please contact your system administrator."

The Troubleshooting Log shows the following error:

"Attribute with name loginName is not supported. Reason: loginName"

The error message can show other attributes as well, depending on the scenario.

Solution::

See KBA 2954081 - Attribute with name loginName is not supported.

Error: "Not supported attribute"

Symptom::

User is trying to sign in to an application through Identity Authentication however the authentication is failing. The application sign-in page is coming up after authentication in Identity Authentication.

In the Troubleshooting log, the following error is displayed:

"message=Identity Provider could not process the authentication request received due to error on its own side.com.sap.security.saml2.lib.common.exceptions.SAML2ErrorResponseException: Not supported attribute.loginName"

Meanwhile SAML trace has the following `nameid` format:

```
<NameID Format="urn:oasis:names:tc:SAML:1.1:nameid-
format:emailAddress"><email_address></NameID>
```

Solution:

See KBA 2954035 - IAS error: Not supported attribute.

Error: "Cookie name is not valid"

Symptom:

Authentication through Identify Authentication is failing. The troubleshooting logs of Identity Authentication, shows the following error:

"... message=""User authentication failed.Cookie name is not valid: ..."

Solution:

See KBA 2698571 - User authentication failed in IAS due to error "Cookie name is not valid".

Error: "Your user was valid until. For assistance, contact your administrator."

Symptom:

When trying to sign in an application protected by an Identity Authentication tenant, the following error message is displayed:

"Your user was valid until <date>. For assistance, contact your administrator."

Solution:

See KBA **2950819 -** "Your user was valid until <date>. For assistance, contact your administrator." error when logging on via Identity Authentication Service.

1.12.14.5 Application Integration

Problems that different applications integrated with Cloud Identity Services may face.

You receive error: "Your registration failed because the URL of the redirect page is invalid. Please contact your system administrator"

Symptom:

User registration on the SAP Cloud Platform Identity Authentication Service tenant fails and the following error is shown:

"Your registration failed because the URL of the redirect page is invalid. Please contact your system administrator"

Solution:

See KBA **2743394** - Your registration failed because the URL of the redirect page is invalid.

You receive error: Error: "Your domain is not trusted. Please contact your system administrator"

Symptom::

When using embedded frames or overlays in an application that authenticates against the Identity Authentication, the following error is displayed when trying to log in via the domain of the overlay:

"Your domain is not trusted. Please contact your system administrator."

The other error can be related to trusted domains:

"Your request failed because the page you have to be redirected to is not trusted. Please contact your system administrator."

Solution:

See KBA **2739473** - "Your domain is not trusted. Please contact your system administrator" in Identity Authentication Service

You receive error: "The digital signature of the received SAML2 message is invalid"

Symptom:

An Identity Authentication tenant returns the message: "The digital signature of the received SAML2 message is invalid" in subject when an authentication request is done from a specific service provider. This can be checked via a SAML tracer (see SAP KBA 2461862 Collecting SAML traces with Chrome or Firefox).

In case the service provider is an SAP BTP subaccount, the **Error 500** can be seen on the screen.

In the Troubleshooting log, the following error is displayed:

"message=Identity Provider could not process the authentication request received due to error on its own side. An unexpected exception occurred. See call stack for details. Caused by: Signature of the SAML2 protocol token cannot be validated because neither primary nor secondary certificates are available in the configuration"

Solution:

See KBA 2645425 - The digital signature of the received SAML2 message is invalid

Integration with SAP IBP. IBP logon screen is received after authentication (SSO doesn't work)

Symptom:

- You need to Integrate SAP Integrated Business Planning (SAP IBP) with either Identity Authentication or a corporate identity provider (IdP).
- The authentication happens to IBP via **Identity Authentication** or corporate IdP, but the IBP sign-in screen is received after authentication (SSO doesn't work).

Solution:

See KBA 2659221 - User authentication prerequisites for IBP with Identity Authentication Service or Corporate IdP.

Proxy scenario with S4/HANA

Symptom:

There is a need to access the S/4HANA application with Identity Authentication that is used as a proxy.

At sign in attempt, an error message is shown depending on the application is used to log in.

Solution:

See KBA 2762530 - https://launchpad.support.sap.com/#/notes/2762530.

SFSF password migration isn't taking effect

Symptom:

After provisioning users to Identity Authentication from SuccessFactors (through Identity Provisioning), users can't sign in to SuccessFactors with a `username` and `password`. They use the forgot password link and get an error message on the Identity Authentication sign-in page:

Passwords can only be changed once every %{param0} hours.

or

Passwords can only be changed once every 24 hours.

In the troubleshooting logs of Identity Authentication with "WARN" Severity, you see the error:

"Cannot send Forgot Password Mail to user with uid <P_UserID>. Reason: PASSWORD_DISABLED. "

other factors are:

- SuccessFactors password migration to Identity Authentication has been configured Migrating Passwords from SAP SuccessFactors to the Identity Authentication Service .
- Users with the issue are existing already in Identity Authentication prior to running the Identity Provisioning sync job.
- Users with the issue initially try to sign in but their password doesn't work. They reset the password and try to sign in again. This is when the error is received.

Solution:

See KBA 2957801 - SFSF password migration is not taking effect - "Passwords can only be changed once every %{param0} hours" upon forgot password.

Authentication is returning error in incognito mode, through Identity Authentication overlay sign-in page

Symptom:

The authentication through Identity Authentication service is working fine in Google Chrome (or any other browser) through embedded frame, also called overlay, for the sign-in page of their application.

However, the incognito mode shows "HTTP Status 400 – Bad Request error." The error may occur only at the second login attempt.

Solution:

See KBA

Partial SSO after Identity Authentication implementation on SuccessFactors

Symptom:

- On SuccessFactors instances integrated with Identity Authentication, how no-SSO users can access the instance?
- How to implement a similar feature to the Partial SSO from SuccessFactors on Identity Authentication.

Solution:

See KBA **2954556** - How to implement Partial SSO after Identity Authentication implementation on SuccessFactors

Browser Back button isn't supported when using SAML

Symptom:

Using the browser's *Back* function while applying the Security Assertion Markup Language (SAML) authentication leads to inconsistent results.

Solution:

See KBA 2677653 - Browser Back button is not supported when using SAML

You receive error: "Authentication Token's `targetUrl` is not part of the trusted domains"

Symptom:

There is an application using overlay in Identity Authentication for authentication, and the authentication fails with the error: **Your domain is not trusted, please contact your system administrator**.

Meanwhile, in the Troubleshooting log, the following error can be seen: **Authentication Token's targetUrl is not part of the trusted domains. Redirecting to error page.**

Solution:

See KBA **2944969** - Authentication Token's targetUrl is not part of the trusted domains

S-user provided in the Upgrade Center isn't assigned Identity Authentication admin role

Symptom:

The integration between SuccessFactors (SFSF) and Identity Authentication has been initiated.

After the integration, the administration console for Identity Authentication (`https://<tenantID>.accounts.ondemand.com/admin/`) with the user provided in the `Upgrade Center` can't be accessed.

Error: **"Sorry, we could not authenticate you. Try again."** is shown in the popup.

Solution:

See KBA **2983379** - S-user provided in the Upgrade Center is not assigned IAS admin role

User presence prerequisites for SAP Hybris Cloud with Identity Authentication Service

Symptom:

There is a need to Integrate SAP Hybris Cloud with Identity Authentication and would like to know where users will be maintained.

Solution:

See KBA **2665797** - User presence prerequisites for Hybris Cloud with Cloud Identity Authentication Service

1.12.14.6 Request, Create, and Delete Identity Authentication Tenant

Problems related to requesting, creating, or deleting a tenant.

Identity Authentication provides one productive tenant per customer, regardless of the number of contracts signed in which Identity Authentication is included or bundled.

For more information about the tenant model and tenant licensing of Identity Authentication, see Tenant Model and Licensing. For the obtaining a tenant, see Get Your Tenant [page 528].

If you don't find your solution in the documentation, see the following suggestions:

I purchased a tenant, but it hasn't been provisioned yet

Symptom:

An Identity Authentication tenant has been purchased but hasn't been provisioned yet.

Solution:

See KBA 2751968 - Details required when requesting an Identity Authentication tenant

How to request additional Identity Authentication Service tenants

Symptom:

There is a need to request additional Identity Authentication tenants besides already existing ones.

Solution:

See KBA - How to request additional Identity Authentication Service tenants.

I can't find Identity Authentication tile in SAP BTP cockpit

Symptom:

You can't find the Identity Authentication tile in *SAP BTP cockpit* > *Services*.

Solution:

See **KBA 2711456** - Identity Authentication tile in SAP BTP Cockpit

1.12.14.7 End user screens

Problems that you may face when working with the end user screens.

You need to remove the "Forgot password" link from the sign in screen

Symptom:

You need to remove the *Forgot Password* link from the Identity Authentication sign-in screen. This can be a goal when the Corporate User Store is used, and the password is managed on the Corporate User Store itself, so the forgot password functionality would not be needed.

Solution:

See **KBA 2607588** - How to remove Forgot Password link from Identity Authentication logon page.

Missing X-Frame-Options from accounts.ondemand.com HTTP header

Symptom:

X-Frame-Options HTTP header is missing from the IAS tenant sign in page, `https://<tenantID>.accounts.ondemand.com`

Solution:

See KBA **2989320** - Missing X-Frame-Options from accounts.ondemand.com HTTP header.

1.12.14.8 REST APIs

Problems that you may face when using the REST APIs of Cloud Identity Services.

SCIM REST API request fails with Status code 415 Unsupported Media Type

Symptom:

Your SCIM requests are failing with **Status code 415 Unsupported Media Type** error when you use one of the Manage Users SCIM REST API.

Solution:

See **KBA 2942542** - SCIM REST API request fails with Status code 415 Unsupported Media Type

You receive error: "500 Internal Server Error"

Symptom:

While creating a user with Cloud Identity Services SCIM REST API, the REST client returns the following: **"500 Internal Server Error"**

Solution:

500 Internal Server Error usually can be caused by an incorrectly created script. See: KBA **2745866** - SAP Cloud Platform Identity Authentication Service - "500 Internal Server Error" while creating user with SCIM REST API

Change Tenant Texts REST API fails with "403 Forbidden"

Symptom:

Logon labels can't be customized since the POST API isn't reachable due to **"403 Forbidden"** error:

This is a legal request, but the server is refusing to respond to it. Unlike the **401 Unauthorized** response, where authenticating will make no difference.

Solution:

See KBA **2650614** - Identity Authentication Service - Cannot change logon screen labels - 403 Forbidden

User update fails with "400 Bad Request"

Symptom:

User update via the Identity Authentication API or the administration console fails with 400 Bad Request or Bad Request. The user can't be updated.

Solution:

See KBA 2895736 - 400 Bad Request when updating user in Identity Authentication Service

403 Forbidden error

Symptom:

Calling the SCIM REST API of Identity Authentication via a REST client returns a 403 Forbidden error.https://launchpad.support.sap.com/Create%20User%20Resource

Solution:

See KBA 403 Forbidden when requesting URI: https://<tenant ID>.accounts.ondemand.com/service/scim/Users

"Value not supported for attribute department" when updating a user via the SCIM API

Symptom:

When updating a user in Identity Authentication using the SCIM API, the following error is displayed:

"StatusCode: BadRequest Message: Processing of the HTTP request resulted in an exception. Please see the HTTP response returned by the 'Response' property of this exception for details. Web Response: Value not supported for attribute department. For more information about supported values, see Identity Authentication Documentation. This operation was retried 0 times. It will be retried again after this date: 2020-05-26T18:22:53.1296153Z UTC"

Solution:

See KBA 2931057 - "Value not supported for attribute department" when updating an user via the SCIM API.

A new Identity Authentication tenant user activation link redirects to a password change screen

Symptom

A new user activation link redirects to a password change screen, however, the activation link is correct.

Solution:

See KBA **2770762** - The Identity Authentication activation link redirects to password change screen.

How to retrieve users who enabled TFA (Two-Factor Authentication) in Identity Authentication using SCIM REST API

Symptom:

I don't know how to retrieve/search users who enabled TFA (Two-Factor Authentication) in Identity Authentication by using SCIM REST API.

Solution:

See KBA **2942076** - How to retrieve users who enabled TFA (Two-Factor Authentication) in IAS using SCIM REST API.

How to mass update user password in Identity Authentication

Symptom:

A large number of passwords need to be updated. One by one isn't a solution.

Solution:

See KBA 3001615 - How to mass update user password in Identity Authentication.

1.12.14.9 Corporate Identity Providers

Problems that you may face with corporate identity providers (IdPs) when using Cloud Identity services as a proxy.

SSO with Corporate Identity Provider fails in some browsers/devices

Symptom:

One or both of the following issues are occurring:

- Single Sign-On (SSO) with corporate IdPs fails in the Cloud Identity services with the following error **"Identity provider cannot process the response due to wrong configuration. Please contact your system administrator".**
- SAML2.0 Authentication on SAP Business Technology Platform (SAP BTP) fails with the following error **"HTTP 400 Bad Request."**

In addition, one or both of the following statements are true:

- The problem occurs in some browsers/devices, but not in others
- The problem occurs only in a normal browser window, but not in private/incognito, or the other way around.

Solution:

See KBA **2946518** - SSO with Corporate Identity Provider fails in some browsers/devices.

Given URL does not contain SAML2 authentication request for validation

Symptom:

SAML 2.0 authentication when using Cloud Identity services fails and errors similar to the following ones are recorded in the Troubleshooting log:

"ERROR#com.sap.security.saml2.idp.endpoints.sso.SSOEndpoint##"

"#Identity Provider could not process SAML2 authentication request sent over Redirect due to SAML2 core error that prevents sending error response to the caller."

"Reason: [Given url: <URL DETAILS> does not contain SAML2 authentication request for validation.]"

Solution:

See KBA **2698094 -** Given url does not contain SAML2 authentication request for validation.

Cloud Identity services as proxy to Google fails with 403 app_not_configured_for_user

Symptom:

Cloud Identity services as proxy to Google Workspace fails with the following errors:

"Error: app_not_configured_for_user"

"Service is not configured for this user."

Solution:

See KBA **3030557** - Identity Authentication as proxy to Google fails with 403 app_not_configured_for_user.

Signature validation of SAML2Assertion failed

Symptom:

Cloud Identity services is acting as a proxy, the authentication happens through a corporate identity provider.

When logging in, users are redirected back to the login page and get in a loop.

In the Troubleshooting log, the following error is displayed:

"Signature validation of SAML2Assertion failed. Signature validation of SAML2Assertion failed. Caused by: Signature not valid!"

Solution:

See **KBA** - 3026204 Signature validation of SAML2Assertion failed

Name id attribute must match at least one valid and supported user attribute value

Symptom:

Cloud Identity services is acting as a proxy, the authentication happens through a corporate identity provider.

Subject Name Identifier is set to `${corporateIdP.<corporateIdP attribute>}`. Identity Federation is enabled - user does exist in the Identity Directory user store.

Authentication is failing with such user, and the Troubleshooting Log is showing the following error message:

SAML configuration error. Name id attribute `${corporateIdP.<corporateIdP attribute>}` must match at least one valid and supported user attribute value

Solution:

See KBA **2976923** - **Name id attribute ${corporateIdP.<corporateIDP attribute>} must match at least one valid and supported user attribute value**.

HTTP Status 400 - Identity Provider could not process the logout message received - Identity Authentication

Symptom:

After logging out of an application via SAML configured for the Cloud Identity services, the logout fails with the following error message:

"HTTP Status 400 - Identity Provider could not process the logout message received"

Solution:

See **KBA** - 2682874 HTTP Status 400 - Identity Provider could not process the logout message received - Identity Authentication.

SAML2Assertion doesn't specify `Subject NameID`

Symptom:

SAML 2.0 authentication when using Cloud Identity services or SAP NetWeaver Application Server for Java (SAP AS Java) as the service provider (SP) fails and errors similar to those below are recorded in the Troubleshooting log:

Authentication error.SAML2Assertion does not specify Subject NameID.

authenticationMethod=saml2Assertion

Solution:

See KBA **2908718** - SAML2Assertion does not specify Subject NameID.

Service Provider does not match specified audience in the SAML2Assertion

Symptom:

SAML 2.0 authentication when using Cloud Identity services fails and errors similar to below are recorded in the Troubleshooting log:

ERROR#com.sap.security.saml2.idp.endpoints.sso.ACSEndpoint#

Authentication error. Reason: [Service Provider does not match specified audience in the SAML2Assertion.]

Solution:

See KBA **2693814** - Service Provider does not match specified audience in the SAML2Assertion.

Logout Redirect URL is not working when Cloud Identity services is acting as a proxy

Symptom:

Logout Redirect URL is not working when Cloud Identity services is acting as a proxy. Logout Redirect URL is configured, but the logout is ending at the Single Logout Endpoint HTTP-Redirect URL.

Solution:

See KBA **2976906** - Logout Redirect URL is not working when IAS is acting as a proxy.

IdP not returning attribute `InResponseTo` in the response with the ID

Symptom:

A corporate identity provider is configured and Cloud Identity services is used as a proxy. Cloud Identity services sends an authentication request to the corporate IdP with an ID, but the IdP is not returning the attribute `InResponseTo` in the response with the ID.

Meanwhile, Cloud Identity services is showing the following error:

"Identity provider cannot process the response due to wrong configuration. Please contact your system administrator."

Solution:

See KBA **2926867** - InResponseTo attribute - What does IAS expect when it is used as a proxy - How To.

User attribute configured for `name-id format unspecified` is not supported

Symptom:

Authentication to an application fails when using Cloud Identity services. In the application logs and, or in the SAML trace, the error **"User attribute configured for name-id format unspecified is not supported"** can be seen.

Solution:

See KBA **2594230** - User attribute configured for name-id format unspecified is not supported.

Error "Identity Provider could not process SAML2 logout message. RedirectPayload is not signed."

Symptom:

SAML 2.0 authentication when using Cloud Identity services as the IdP fails and errors similar to those below are recorded in the Troubleshooting log:

ERROR#com.sap.security.saml2.idp.endpoints.slo.SLOEndpoint##

Identity Provider could not process SAML2 logout message. RedirectPayload is not signed.

Solution:

See KBA **2811941** - **Identity Provider could not process SAML2 logout message.RedirectPayload is not signed.**

Cloud Identity services as proxy to ADFS or Azure fails because of the Scoping tag

Symptom:

Microsoft ADFS or Azure is set as a Corporate Identity Provider to delegate authentication from a Cloud Identity services tenant.

Authentication is not working on the ADFS/Azure side and either of the following messages is seen:

The SAML authentication request element 'Scoping' is not supported.

The SAML authentication request property 'Scoping/ProxyCount' is not supported.

Solution:

See KBA **2615705** - Identity Authentication Service as proxy to ADFS or Azure fails because of the Scoping tag.

How to connect Ping Identity to Cloud Identity services

Symptom:

There is a need to configure Ping Identity as a corporate identity provider for Cloud Identity services.

Solution:

See KBA **2968405 -** How to connect Ping Identity to Identity Authentication Service.

How to connect Azure Active Directory to Cloud Identity services

Symptom:

There is a need to configure Azure as a corporate IdP to SAP Cloud Identity Services.

Solution:

See KBA **2945035** - How to connect Azure Active Directory to Identity Authentication Service.

How to configure Okta as corporate identity provider with Cloud Identity services

Symptom:

There is a need to configure Okta as corporate IdP for an application with SAP Cloud Identity Services as proxy.

Solution:

See KBA **2943651** - How to configure Okta as corporate identity provider with Identity Authentication.

Incorrect destination when using Okta corporate IdP with Cloud Identity services

Symptom:

When using theSAP Cloud Identity Services tenant as a proxy in a corporate IdP-initiated login scenario with the corporate IdP Okta, the following error appears:

Error:**Identity Provider could not process the authentication request received. Delete your browser cache and stored cookies, and restart your browser. If you still experience issues after doing this, please contact your administrator.**

Solution:

See KBA **2753454** - Incorrect destination when using Okta corporate IDP with Identity Authentication Service.

Error with ADFS: "SAML2Assertion does not specify Subject NameID"

Symptom:

SAP Cloud Identity Services is acting as a proxy with Active Directory Federation Services (AD FS). After authentication to an application, it fails with the error HTTP Status 500.

Meanwhile, in the Troubleshooting log, the following errors can be seen:

- **Authentication error. The authentication process did not set an authenticated principal in the current thread.**
- **state=failed, action=login, objectType=user, cause=authenticationStepFailure, category=audit.authentication, credentialType="{TRUSTED_IDP_SAML_ASSERTION=rejected}**
- **SAML2Assertion does not specify Subject NameID.com.sap.security.saml2.sp.sso.exception.BadCredentialsException: SAML2Assertion does not specify Subject NameID.**

Solution:

See KBA **2945414** - 'SAML2Assertion does not specify Subject NameID' error with AD FS.

Note: This topic fails to consulting category. Microsoft is responsible to do this configuration. However, this KBA provides some hints to troubleshoot and solve this issue.

Error: "Identity provider cannot process the response due to wrong configuration. Please contact your system administrator."

Symptom:

A corporate identity provider is configured and IAS is used as a proxy. The authentication is failing and IAS is showing the following error:

"Identity provider cannot process the response due to wrong configuration. Please contact your system administrator."

Solution:

See KBA **2926891 -** RelayState attribute - What does IAS expect when it is used as a proxy - How To.

Error: "Could not find user xxx in mongo DB."

Symptom:

- Corporate Identity Provider is configured for authentication in Identity Authentication, but authentication is failing.
- The Troubleshooting log is showing the following error:
  "Authentication error.User not found: xxx Caused by: Could not find user <test@mail.com> in mongo DB." ensure that the Identity Authentication Troubleshooting log to contains "Could not find user <test@mail.com> in mongo DB" error, before proceeding with the resolution of this KBA.

- You may see the response from the service provider :
  "StatusCode in ResponseMessage != OK; please refer to the database trace for more information"

Solution:

See KBA **2908064** - Identity Authentication: Could not find user xxx in mongo DB.

HTTP 500 error from corporate identity provider - Certificate used to validate the signature cannot be null

Symptom

Sign-in to Corporate Identity Provider (IdP) does not work with the Identity Authentication Service (IAS) functioning as a proxy. Corporate IdP login screen shows an "HTTP 500" error.

In Troubleshooting Logs, the following entries can be seen:

"POST /saml2/idp/acs/<TenantID>.accounts.ondemand.com HTTP/1.1" 200

severity=INFO, location=umtrace, crtAccount=<TenantID>, authenticatedSubject="anonymous", state=failed, action=authenticate, objectType=user, authenticationMethod=saml2Assertion, category=audit.configuration, correlationId

#ERROR#com.sap.security.saml2.idp.endpoints.sso.ACSEndpoint##<TenantID>#anonymous#http-bio-127.0.0.1-8080-exec-5#na#N/A#N/A#N/A#Authentication error.SAML2Response signature verification failed. Caused by: The certificate used to validate the signature cannot be null

However, SAML response is successful:

<...>

<samlp:Response xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol" xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"

<...>

*<dsig:X509Certificate><...></dsig:X509Certificate><...><samlp:Status><samlp:StatusCode Value="urn:oasis:names:tc:SAML:2.0:***status:Success***"*

<...>

Solution:

See KBA **2758293** - IAS proxy scenario: HTTP 500 error from corporate identity provider - Certificate used to validate the signature cannot be null.

1.12.14.10 Corporate User Store

Problems with corporate user store scenarios.

Corporate user store in Cloud Foundry environment

The corporate user store feature is supported in the Cloud Foundry subaccount.

For more information about the configuration steps, see Corporate User Store (Cloud Foundry Environment).

See also KBA **3058176** - Corporate User Store Feature in Cloud Foundry environment.

Corporate user store in Neo subaccount

The corporate user store feature is supported in the Neo subaccount.

For more information about the configuration steps, see Corporate User Store (Neo Environment).

See also KBA **2768285** - OAuth Client subscription type "sci/proxy" not visible.

How to connect Identity Authentication to on-premise user store

Symptom:

There is a need to integrate Identity Authentication to an on-premise user store so that users can use their corporate credentials to access cloud applications.

Solution:

See KBA **2461375** - How to connect Identity Authentication to on-premise user store.

You need to remove the "Forgot password" link from the sign in screen

Symptom:

You need to remove the *Forgot Password* link from the Identity Authentication sign-in screen. This can be a goal when the Corporate User Store is used, and the password is managed on the Corporate User Store itself, so the forgot password functionality would not be needed.

Solution:

See **KBA 2607588** - How to remove Forgot Password link from Identity Authentication logon page.

How to reset password for users from Corporate User Store

Symptom:

There is a need to reset the Identity Authentication service password for a user coming from the Corporate User Store. When the e-mail received to reset the password is followed, the sign-in is successful. However, at the next sign-in attempt, the newly set password does not work anymore.

Solution:

See KBA **2757021** - Identity Authentication - Password reset for users from Corporate User Store.

ABAP as Corporate User Store for Identity Authentication Service

Symptom:

There is a need to use SAP NetWeaver AS ABAP on-premise user store in addition to Identity Authentication own cloud user store.

Solution:

See KBA **2942094** - SAP AS ABAP as Corporate User Store for SAP Identity Authentication Service (IAS).

SAML 2.0 Response issue instant is not valid

Symptom:

A corporate identity provider is configured for Identity Authentication. The authentication fails with an error, meanwhile, in the Troubleshooting log, the following error is shown:

SAML2Response issue instant is not valid.com.sap.security.saml2.sp.sso.exception.BadCredentialsException: SAML2Response issue instant is not valid.Issue Instant is not valid anymore. IssueInstant: <Date>Curent time: <Date>

The caused by can be the following as well, depending on the time setting on the AD FS: **Caused by: Issue Instant is not valid yet.**

Solution:

See KBA **2945159** - SAML2Response issue instant is not valid.

OAuth Client subscription type "sci/proxy" not visible

Symptom:

There is a need to set a subscription type to "sci/proxy" during the OAuth 2.0 configuration.

The "sci/proxy" option in the drop-down list is not present.

Solution:

See KBA **2768285** - OAuth Client subscription type "sci/proxy" not visible.

Error: "End-user gets a "Sorry, we could not authenticate you. Try again" error when attempting to log in with LDAP user store"

Symptom:

An LDAP user store on Identity Authentication is configured, but the end-user is getting a "**Sorry, we could not authenticate you. Try again**" error when attempting to log in.

Solution:

See KBA **2680867** - Check if the system user is locked when configuring and LDAP user store.

1.12.14.11 Kerberos Authentication

Problems with Kerberos authentication scenarios.

Error "Kerberos Authentication fails with Could not decrypt the encrypted data error"

Symptom:

Kerberos authentication is configured for Identity Authentication to allow users to log on without a username and password when they are in the corporate network based on Configure Kerberos Authentication' SAP Help documentation.

However, users are still prompted to authenticate with a username and password.

The Troubleshooting Log shows the following error:

Could not validate SPNEGO token: Could not decrypt the encrypted data

Solution:

See KBA **2958786** - Kerberos Authentication fails with Could not decrypt the encrypted data error.

Kerberos Authentication fails with Unsupported encryption SPNEGO token type error

Symptom:

Kerberos authentication is configured for Identity Authentication to allow users to log on without a username and password when they are in the corporate network based on Configure Kerberos Authentication SAP Help documentation.

However, users are still prompted to authenticate with a username and password.

The Troubleshooting Log shows the following error:

Unsupported encryption SPNEGO token type

Solution:

See KBA **2958806** - Kerberos Authentication fails with Unsupported encryption SPNEGO token type error.

Supported number of realms or domains for Kerberos/SPNEGO in Identity Authentication

Symptom:

There is a need to know how many realms or domains are supported for Kerberos/SPNEGO Authentication in Identity Authentication.

Solution:

See KBA **2726591** - Supported number of realm or domain for Kerberos/SPNEGO in IAS.

1.12.14.12 Risk-Based Authentication

Problems that you may face when configuring or using with risk-based authentication.

Error: "Sorry, but you are currently not authorized for access"

Symptom:

SAML 2.0 authentication when using Identity Authentication fails and a similar error to below is shown:

Sorry, but you are currently not authorized for access

The Troubleshooting log is showing one the following errors:

cause=rbaRulesCheckFailure, message="Denied by RBA rules" or **"Authentication error. User not found: xxx Caused by: Could not find user <e-mail> in mongo DB."**

Solution:

See KBA **2891275** - Sorry, but you are currently not authorized for access: IAS issue.

Two-Factor Authentication is not taking effect in Identity Authentication

Symptom:

Enable two-factor authentication for an application via risk-based authentication rules.

There is no change in the behavior during sign-in.

Solution:

See KBA **2941888** - Two-Factor Authentication is not taking effect in IAS.

Passcode not valid upon Two-Factor Authentication

Symptom:

The passcode generated for two-factor authentication is invalid for a mobile device.

Solution:

See KBA **2968616** - Passcode not valid upon Two-Factor Authentication.

Custom Domains [page 3069]

1.12.14.13 Custom Domains

Problems that you may face when using custom domains in Identity Authentication.

Error: "Invalid certificate Subject DN. Please make sure that the Subject DN of the uploaded certificate is the same as the configured one."

Symptom:

The following error is shown after the certificate, received from the CA, is uploaded:

Invalid certificate Subject DN. Please make sure that the Subject DN of the uploaded certificate is the same as the configured one.

Solution:

See KBA **2922845** - Invalid certificate Subject DN. Please make sure that the Subject DN of the uploaded certificate is the same as the configured one.

It is not possible to rename the Identity Authentication tenant

Symptom:

There is a need to change the `tenant ID` of your Identity Authentication tenant that is part of the URL:

`tenant ID>.accounts.ondemand.com/admin`

Solution:

See KBA 2774169 - Rename Identity Authentication tenant is not possible.

Custom domain in Identity Authentication using a wild-card certificate

Symptom:

There is a need to configure a custom domain in Identity Authentication, using an existing wild card certificate.

Solution:

See KBA 2922427 - Custom domain on IAS using wildcard certificate.

1.12.15 Troubleshooting Provisioning Issues

While using the Identity Provisioning service, you might encounter issues or have questions regarding specific settings, limitations, or other aspects.

For a step-by-step walkthrough of the administration console for SAP Cloud Identity Services, refer to the following video on using guided tours while navigating within the provisioning systems and logs.

The following topics provide detailed information and steps to help you identify and resolve common issues that may arise during your experience with the Identity Provisioning service.

- Administration Issues [page 3071]
- Job and Transformation Issues [page 3077]
- Error Messages [page 3111]
- Entity Deletion Issues [page 3121]
  Learn how to troubleshoot the most frequent reasons for deletion of users or groups from a target system by the Identity Provisioning.
- Additional Information [page 3130]
- Handling Specific Attributes [page 3137]

1.12.15.1 Administration Issues

Can't Enable a Disabled System

Problem:

- A previously enabled system (source, target or proxy) is now disabled.
- You choose the icon to edit the system status.
- The *Enable* button is inactive (grayed out).

Find the root cause for your problem in the cases below:

A Feature Was Explicitly but Only Temporarily Enabled

Problem:

(Bundle, Standalone) A particular system is disabled because it uses a feature that was only temporarily enabled.

Solution:

If you still need this feature, you can request it again by contacting the Support team. Create an incident for component *BC-IAM-IPS*. In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

One of Your Bundles Has Expired

Problem:

(Bundle) You use the Identity Provisioning service as part of an SAP cloud solution. The systems belonging to the relevant bundle are disabled, indicating that the license for the relevant product has expired.

Solution:

To enable your inactive systems and continue using them, extend your bundle license.

Beta Features Are Disabled

Problem:

(Standalone) A particular system is disabled because it's available only when Beta features are enabled.

Solution:

Beta features might be disabled for your subaccount. To verify this, follow the steps below:

1. In the SAP BTP cockpit, navigate to your global account.
2. On your subaccount tile and choose *Edit*.

3. For *Beta Features*, select the *Enable* checkbox.
4. Refresh your administration console for SAP Cloud Identity Services to see if the disabled system is now available.

System Is Still Disabled

Your problem requires deeper analysis by SAP. Please create an incident for component **BC-IAM-IPS**.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning-> Service Plan.

Before you open an incident, read:

2654164 - What to consider before opening a Support Ticket for SAP Cloud Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Can't Create Another System

Problem:

1. You have added a certain number of source or target systems in the administration console for SAP Cloud Identity Services.
2. You choose *Add* to create a new one.
3. A warning message appears, saying that you have reached the maximum number of source or target systems allowed for your subaccount.

Reason

By default, you are allowed to create up to **20** source and **50** target systems for your subaccount.

Solution:

1. Check if there is a system that is no longer relevant to your business scenario.
2. If you think you might still need it in future, export it first as a JSON or a CSV file.
3. Delete that system from the UI.
4. Add a new source/target system.

If your business case requires more productive source systems, create an incident for component **BC-IAM-IPS** to request the number of additional systems. In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*.

Can't Get or Grant Admin Permissions for a Bundle

You use the Identity Provisioning service as integrated in an SAP cloud product. To learn more, see: Get Your Tenant [page 528]

You don't know who is the administrator of your bundle tenant, or how to grant other users *Administrator* permissions.

Depending on your case, you can find more information below:

You Don't Know Who Is Administrator

Problem:

You need admin rights for your Identity Provisioning bundle tenant. You have to ask the initial (or a secondary) administrator for your bundle tenant but you don't know who they are.

Solution:

You can view all your SAP Cloud Identity Services tenants by using the *SAP Cloud Identity Services - Tenants* application. You can access it at the following URL: https://iamtenants.accounts.cloud.sap/Information. This tool displays the tenant administrators, the type of your tenant (test or productive), the date it was created, and the region where it is available.

If you still struggle and can't find any administrator yourself, create an incident for component **BC-IAM-IPS** and request the contacts of the initial tenant administrator.

You Are Administrator

Problem:

You are either the initial administrator of your Identity Provisioning bundle tenant, or another admin user has granted you such permissions. Now, other users ask you to grant them admin permissions too, but you don't know how to do it, or what tool to use.

Solution:

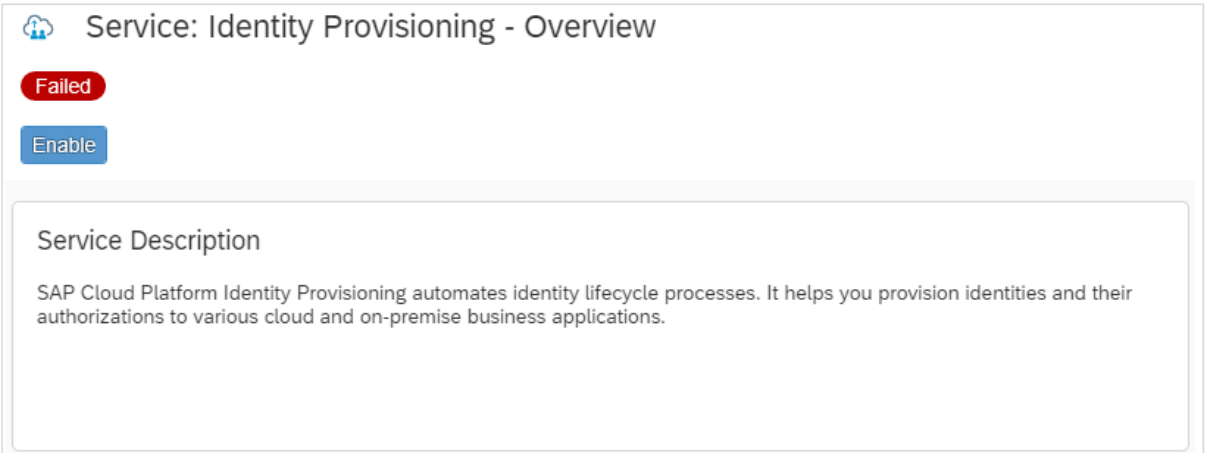
Open the administration console for SAP Cloud Identity Services and choose the *Authorizations* tile. It allows you to grant admin rights to as many additional users as you want.

To learn how, see: Manage Administrators [page 543].

(Standalone) Enabling the Identity Provisioning Service Fails

Problem:

1. You have a global account in the SAP BTP cockpit.
2. In one of your subaccounts, you open the *Identity Provisioning* tile.
3. You choose *Enable* but the operation fails.
4. Even if you try several times, you cannot enable the service.



Reason and Solution

There might be different reasons for failed enabling. The most common ones are:

Reason	Solution
The Identity Provisioning service is currently down.	Create an incident for component *BC-IAM-IPS* and we'll investigate the issue.
In your global account, you have enabled the Identity Provisioning for two subaccounts, and you're trying to enable it for a third one. You are not allowed to do this because, by default, you can enable the service only for *two* subaccounts per global account.	If you have already enabled the service for two subaccounts, and want to raise the quota for your global account to three or more subaccounts, create an incident for component *BC-IAM-IPS*. Request the number of additional subaccounts.

In the created incident, specify also:

- The IDs of your global account and subaccount.
- To which region your account belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Identity Provisioning Tile Is Missing In the SAP BTP Cockpit

Your access to the *Identity Provisioning* tile in SAP BTP cockpit depends mostly on the type of product you have purchased. You have one of the following:

- *Identity Provisioning service integrated (bundled) in an SAP cloud product*
  Problem:
  1. You already have a production global account and use at least one subaccount for non-identity provisioning purposes (that is, other services and cloud tasks).
  2. After purchasing an SAP cloud product (see the list of available bundle options), you request and receive access to the Identity Provisioning service. You can open the administration console for SAP Cloud Identity Services by using two URLs related to two subaccounts (one for testing purposes and one for productive use). These subaccounts are new, and not to be confused with any you already have.

3. You try to access the *Identity Provisioning* tile via the SAP BTP cockpit, using your "previous" subaccount:
    - In the cockpit, you choose the previous subaccount.
    - From the left-side navigation, you choose *Services*.
    - You don't see a *Provisioning Service* tile.

Reason & Solution:

Even though you have obtained the Identity Provisioning service as part of a bundle product, it's not bound to your previous subaccount. The service is bound only to the subaccounts you've received from SAP, which have been specifically created for your Identity Provisioning scenarios.

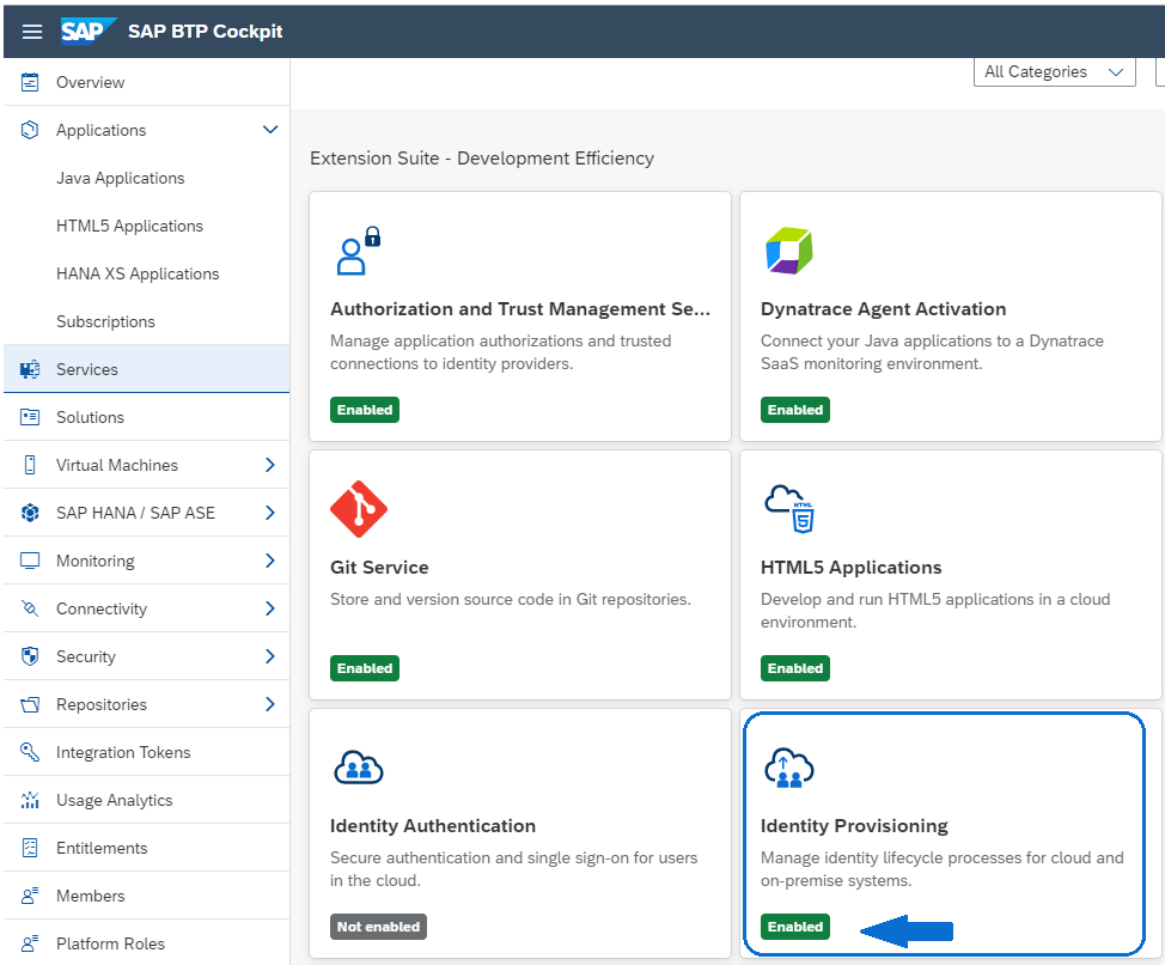
Also, you won't be able to select the *Provisioning Service* tile from either of these two subaccounts. That's because you're not intended to control the service from the cockpit.

- *Identity Provisioning service as a standalone product*

  Make sure you use the correct (sub)account that is bound to your Identity Provisioning license. Then:

  1. Log on to the SAP BTP cockpit: https://<region>.hana.ondemand.com.
  2. Go to your global account and choose your subaccount.
  3. From the navigation area, choose Your problem requires deeper analysis by SAP. Please create an incident for component *Services*.
  4. Browse through this page and find the *Extension Suite – Development Efficiency* section.
  5. You should see an *Identity Provisioning* tile.
  6. The default status of the service is *Not enabled*. Choose *Enable*.

Your *Services* screen should look like this:



Still Cannot See the Identity Provisioning Tile

If your problem requires deeper analysis by SAP, please create an incident for component *BC-IAM-IPS*.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*.

Before you open an incident, read:

- 2654164 - What to consider before opening a Support Ticket for SAP BTP

For contract-related questions, read:

- 1660069 - How to contact SAP Contracts Department for questions or issues

Related Information

Job and Transformation Issues [page 3077]
Error Messages [page 3111]
Entity Deletion Issues [page 3121]
Additional Information [page 3130]
Handling Specific Attributes [page 3137]

1.12.15.2 Job and Transformation Issues

You have a struggle with a transformation, a property or a provisioning job?

Find your particular problem below:

Entities Are Not Updated or Deleted in the Target System

When you set up your systems and start a manual or scheduled provisioning job, the standard behavior of the process reads all the entities from the source system. This mode prevents data loss and always keeps your target system synchronized with the source. You can also choose to optimize the amount of retrieved data and read only the updated entities (new, updated, deleted). For more information about these modes, see Manage Full and Delta Read [page 2459].

To keep source and target systems completely synchronized, you can use the **Resync** type of provisioning job.

In some cases though, specific entities should be updated or deleted, but during the provisioning job they are not read at all. They are therefore not updated in the target system.

Entities Are Not Updated

Problem:

1. Run a provisioning job (manual or scheduled).
2. The job finishes successfully but some entities have not been updated.

Reason:

You might have set special conditions or expressions in your transformations.

Solution:

1. Make sure that no special conditions or expressions (ignore or skipOperations) are set in the JSON transformation.
2. Run again a **Read** or **Resync** provisioning job.
3. Check to see if the relevant entities have been updated in the target system.

Entities are Still Not Updated in the Target System

If your problem requires deeper analysis by SAP, please create an incident for component BC-IAM-IPS.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Entities Are Not Deleted

Problem

Your business case requires you to delete some entities (users or groups) from both the source and the target system. You proceed as follows:

1. Delete these entities from the source system.
2. Run a provisioning job (manual or scheduled).

As a result, the job finishes either **successfully** or **with error**, and in both cases - the relevant entities are not deleted from the target system.

Job is successful but entities are not deleted

Problem

You have deleted some entities from the source system, and then run a provisioning job.

The job finishes successfully but the relevant entities have not been deleted from the target system.

Reason

You either have set special conditions in your transformations, or have missed to add the `ips.delete.existedbefore.entities` property in your target system configuration.

> **Note**
>
> If the property `ips.delete.existedbefore.entities` has not been added before the job attempting the deletion is run, adding it later will not resolve the problem.

Solution

Resolving this issue depends on whether you have added the `ips.delete.existedbefore.entities` property in your target system before or after running the job attempting the deletion.

The property is added before running the provisioning job:

1. Make sure that no special conditions or expressions are set in the target transformation. That includes: *ignore expression*, *skipOperations* (skipping delete), or *deleteEntity* scope.
2. Run a **Read** or **Resync** provisioning job.
3. Check if the relevant entities have been deleted from the target system.

The property is added after running the provisioning job:

If the property is added after the provisioning job finished successfully, entities recognized as "previously existed ones" cannot be deleted from the target system anymore. In this case, you need to delete them from the target system (for example, manually or via script).

For more information on how to properly delete entities in the target system, see Manage Deleted Entities [page 2463].

EntitiesAre Still Available in the Target System

If your problem requires deeper analysis by SAP, please create an incident for component **BC-IAM-IPS**.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Job finishes with error and entities are not deleted

Problem

You have deleted some entities from the source system. You have not set any special conditions or expressions (*ignore*, *skipOperations*, or *deleteEntity* scope) in the target transformation. You have set property `ips.delete.existedbefore.entities` to *true* in the target system, and then run a provisioning job.

The job finishes with error, and the relevant entities have not been deleted from the target system.

Reason

In the job log, you see that there are failed entities when the job has tried to read them from the source system.

Solution

1. Resolve the failed entities in the source system.
2. Run again a **Read** or a **Resync** provisioning job.
3. Check if the relevant entities have been deleted from the target system.

Entities Are Still Available in the Target System

If your problem requires deeper analysis by SAP, please create an incident for component **BC-IAM-IPS**.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Entities Should Not Be Deleted in the Target System

Problem & Reason

The default behavior of the Identity Provisioning service is:

1. It reads entities from a source system and provisions (writes) them in a target system.
2. If, on a next reading job, the service detects that some previously existed entities are now missing, it considers them as **deleted** (or not active anymore).
3. Thus, the next provisioning job (Read or Resync) deletes such entities from the target system.

However, these entities might still be existing and active but are not read because you have set a filter or condition for some business reason.

You **do not want** the "unread" entities (the ones that do not fulfill the filter/condition) to be deleted from the target.

Solution

To prevent deletion of existing active users in your target system, proceed as follows:

1. Select your target system in the administration console for SAP Cloud Identity Services .
2. Choose the *Transformations* tab and then *Edit*.
3. If you want to keep existing/active users, in the user section, add the following mapping:

Sample Code

```
{
 "constant": false,
 "targetPath": "$.active",
 "scope": "deleteEntity"
 }
```

This way, every time you use a filter or a condition, only the relevant filtered entities (users) will be created or updated.

The rest users will remain as is - not updated but not deleted as well.

To learn more about this scope and see specific examples for SCIM systems, see: Transformation Expressions [page 391] ▶ *scope* ▶ *deleteEntity* ◀.

Exclude Users from Provisioning to Target Systems

You want to know how to set up your provisioning scenario so that some users are not replicated to the target system based on given criteria.

Let's assume the employees of your company (with email domain `parentCompany.com`) are stored in SAP SuccessFactors along with other users (for example, contractors). You want to replicate some of them to Identity Authentication or SAP Analytics Cloud and exclude the rest (with email domain `contractorsCompany.com`) because they don't need access to those systems to do their job.

For this, you need to specify a condition in the target system that is based on something common the users share, like their email domain.

Proceed as follows:

1. In SAP SuccessFactors, verify that the users you want to exclude have email address.
   The user email is optional and may not be unique in SAP SuccessFactors. However, it's mandatory and unique in Identity Authentication and SAP Analytics Cloud.
2. In the administration console for SAP Cloud Identity Services, select your target system and open its transformation in *Edit* mode.
   Identity Provisioning is embedded in SAP Cloud Identity Services admin console (formerly known as Identity Authentication admin console). If your Identity Provisioning tenant is running on SAP Cloud Identity infrastructure, you can configure and work with provisioning systems there.
3. Depending on your scenario, add one of the following conditions within the user entity:

   Sample Code

   ```
   {
       "user": {
           "condition": "!($.emails[0].value =~ /.*contractorsCompany.com/)",
           "mappings": [
   ```

   Based on this condition, Identity Provisioning will provision only users that do not have email domain `contractorsCompany.com`. Users with this domain will be read from the source but will be skipped in the target system.

   Sample Code

   ```
   {
       "user": {
           "condition": "$.emails[0].value!= 'user123@contractorsCompany.com'
   ",
           "mappings": [
   ```

   Based on this condition, Identity Provisioning will provision only users that do not have the specified email. Users with this email will be read from the source but will be skipped in the target system. Use this condition in case the users you want to exclude have the same dummy email.
4. (Optional) Run the **Simulate** job from the connected SAP SuccessFactors source system to verify that excluded users are skipped, therefore not provisioned. This test job is available for tenants running on SAP Cloud Identity infrastructure.
5. If the **Simulate** job displays the expected result, run a provisioning job (**Read** or **Resync**).
   Adding a similar condition for excluding users is also applicable to other target systems.

Ensure SAP S/4HANA Cloud Public Edition Users are Replicated During Their Validity Period

You want to ensure that Identity Provisioning service replicates SAP S/4HANA Cloud Public Edition users to the embedded SAP Analytics Cloud during their validity period.

This is handled by the following changed condition in the default read transformation of both - the standard (manually created) and the preconfigured (automatically created) SAP S/4HANA Cloud Public Edition source systems in Identity Provisioning bundle tenants.

Changed condition:

Sample Code

```
{
"user": {
"condition": "($.user.validityPeriod.startDate <= '${currentDate}') &&
($.user.validityPeriod.endDate > '${currentDate}')",
"mappings": [
```

For comparison, the initial condition ensured that SAP S/4HANA Cloud Public Edition users are replicated to the SAP Analytics Cloud during the validity of the *Employee* role of their business partner.

Initial condition:

Sample Code

```
{
"user": {
"condition": "($.validityPeriod.startDate <= '${currentDate}') &&
($.validityPeriod.endDate > '${currentDate}')",
"mappings": [
```

How to proceed:

1. In the administration console for SAP Cloud Identity Services, open the transformation of your SAP S/4HANA Cloud Public Edition source system and check the condition under the user entity.
   - If the read transformation contains the changed condition, no action is required.
   - If the read transformation contains the initial condition, replace it with the changed one. Alternatively, you can create a new SAP S/4HANA Cloud Public Edition source system and configure it manually. The newly created system will contain the changed condition by default.
2. Save your configurations.

Ensure deleted SAP S/4HANA Cloud Public Edition Users are Also Deleted in SAP Analytics Cloud

You want to ensure that users who were deleted in SAP S/4HANA Cloud Public Edition source system will also be deleted in the embedded SAP Analytics Cloud target system.

This is handled by the `ips.delete.existedbefore.entities` property which is now set to *true* in the preconfigured SAP Analytics Cloud target system of the Identity Provisioning bundle tenants for SAP S/4HANA Cloud Public Edition release 1911 or higher.

Initially, this property was not preconfigured in the SAP Analytics Cloud target system and had to be added manually.

How to proceed:

1. In the administration console for SAP Cloud Identity Services, open the *Properties* tab of the embedded SAP Analytics Cloud target system and check if `ips.delete.existedbefore.entities` is set to *true*.
   - If the property is set, no action is required.

- If the property is not set, add it and set it to *true*.

2. Save your configurations.

> **Note**
>
> After successful user provisioning from SAP S/4HANA Cloud Public Edition to SAP Analytics Cloud, if you delete users in SAP S/4HANA Cloud Public Edition and want to provision the change (that is, to delete them) in the target system, you need to set the **`ips.delete.existedbefore.entities=true`** before running the job to delete the users in the target system. If you set it afterwards, the users won't be deleted in SAP Analytics Cloud as they will be recognized as "previously existed ones". In this case, to have them deleted, you need to create an incident on component **LOD-ANA-OEM**.

For more information on the required sequence of steps for deleting users, see Manage Deleted Entities [page 2463].

Groups Are Not Provisioned to the Target System

Problem:

1. You have added a source and a target system in the administration console for SAP Cloud Identity Services. Both systems support provisioning of groups.
2. You have correctly set up these systems. For the source one, you use the default group transformation.
3. Start a provisioning job.
4. View the job results.

In the target system, users are provisioned but groups are missing.

Reason:

In the source system transformations, group provisioning is disabled (ignored) by default.

Solution:

To enable group provisioning, manually change the *ignore* condition to:

> **Sample Code**
>
> ```
> "group": {
>        "ignore": false,
>        "mappings": [
>           {
> ...
> ```

> **Sample Code**
>

> Transformation Expressions [page 391]

Identity Authentication: Provisioned Users Can't Log On

In Identity Authentication target systems, the behavior of the provisioning jobs depends on the constant value set for `$.userType` (in the JSON transformation).

- `"constant": "public"`
  This means that all passwords will be written by default in the Identity Authentication. All provisioned users will therefore be able to successfully log into the administration console for SAP Cloud Identity Services.
- `"constant": "employee"`
  In this case, the login behavior of the provisioned users depends on whether users have been created with or without a password, and where these passwords are stored. You therefore need to modify the target transformations accordingly in order for the users to successfully log in to the administration console for SAP Cloud Identity Services.
  Find your use case from the options below:

Users Are Created Without a Password

This occurs in scenarios in which Identity Authentication acts as a proxy to delegate the authentication to a corporate identity provider.

Solution

Open the Identity Authentication target system transformation and remove the `"constant": "39"` mapping below.

As a result, you should have:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)

<pre>{
    "constant": "false",
    "targetPath": "$.sendMail",
    "scope": "createEntity"
},
{
    "constant": "true",
    "targetPath": "$.mailVerified",
    "scope": "createEntity"
},
{
    "constant": "disabled",
    "targetPath": "$.passwordStatus",
    "scope": "createEntity"
},
// Remove:
{
    "constant": "39",
    "targetPath": "$.sourceSystem",
    "scope": "createEntity"
},
// Make sure you have this
target path with "constant" set to
"employee".
{
    "constant": "employee",
    "targetPath": "$.userType"
},</pre>
	<pre>{
	    "constant": false,
	    "targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sendMail']",
	    "scope": "createEntity"
	},
	{
	    "constant": true,
	    "targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['mailVerified']",
	    "scope": "createEntity"
	},
	{
	    "constant": "disabled",
	    "targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['passwordDetails']
	['status']",
	    "scope": "createEntity"
	},
	// Remove the mapping starting with
	**"constant": "<your-source-system-type-
	code>"**, if its value is set to **39**.
	// Alternatively, set "ignore" to
	true.
	{
	    "constant": **39**,
	    "targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sourceSystem']",
	    "scope": "createEntity",
	    "ignore": **true**
	},
	// Remove this mapping.
	Alternatively, set "ignore" to **true**.
	{
	     "constant": "<your-source-system-
	id>",
	     "targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sourceSystemId']",
	     "scope": "createEntity",
	     "ignore": **true**
	}
	// Make sure you have this
	target path with "constant" set to
	"employee".
	{
	    "constant": "employee",
	    "targetPath": "$.userType"
	},</pre>

→ Tip

If you don't want to delete the `"constant": "39"` section from the transformation, you can configure the *Corporate User Store* in the administration console for SAP Cloud Identity Services so as to reuse the corporate passwords. To learn how, see: Corporate User Store.

Related information: Identity Authentication

Users Still Cannot Log on

Your problem requires deeper analysis by SAP. Please create an incident for component BC-IAM-IPS.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Passwords Are Stored in Corporate User Store

In this case, users are authenticated by Corporate User Store. This is relevant to scenarios that require integration with Cloud Connector. The source system can be AS ABAP, Microsoft Active Directory, or LDAP.

Solution

Open the Identity Authentication target system transformation. For mapping `"targetPath": "$.passwordStatus"`, change `"constant": "disabled"` to `"enabled"`.

Also, if using Identity Authentication (SCIM API version 2), set the value of the `"constant": "<your-source-system-type-code>",` mapping to `39` and set your source system identifier in `"constant": "<your-source-system-id>"`.

As a result, you should have:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)

<pre>{
"constant": "false",
"targetPath": "$.sendMail",
"scope": "createEntity"
},
{
"constant": "true",
"targetPath": "$.mailVerified",
"scope": "createEntity"
},
{
"constant": "enabled",
"targetPath": "$.passwordStatus",
"scope": "createEntity"
},
{
"constant": "39",
"targetPath": "$.sourceSystem",
"scope": "createEntity"
},
// Make sure you have this target path with "constant" set to "employee".
{
"constant": "employee",
"targetPath": "$.userType"
},</pre>
	<pre>{
	"constant": false,
	"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
	"scope": "createEntity"
	},
	{
	"constant": true,
	"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']",
	"scope": "createEntity"
	},
	{
	"constant": "enabled",
	"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['passwordDetails']['status']",
	"scope": "createEntity"
	},
	// Set the value of the **"constant": "<your-source-system-type-code>"**, mapping to **39**.
	// Make sure "ignore" is set to **false**.
	{
	"constant": **39**,
	"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sourceSystem']",
	"scope": "createEntity",
	"ignore": **false**
	},
	// Set the value of the **"constant": "<your-source-system-id>"**, mapping.
	// Make sure "ignore" is set to **false**.
	{
	"constant": "<your-source-system-id>",
	"targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sourceSystemId']",
	"scope": "createEntity",
	"ignore": **false**
	}
	// Make sure you have this target path with "constant" set to "employee".
	{
	"constant": "employee",
	"targetPath": "$.userType"
	},</pre>

Related information: Identity Authentication

Passwords Are Stored in Identity Authentication (initial password)

This use case requires creating an initial password. Users will enter it on their logon to the Identity Authentication service. They can later change this password.

Solution

In the Identity Authentication target system transformation, modify the following JSON mappings:

- For `"$.passwordStatus"`, set "constant" to `"initial"`
- Enter an additional mapping, starting with `"constant": "<initial password defined by customer>"`. Replace `"<initial password defined by customer>"` with an actual initial password. In Identity Authentication (SCIM API version 2), the mapping, starting with `"constant": "<your-initial-password>"`, is part of the default transformation. You only need to replace `<your-initial-password>` with an actual initial password and set `"ignore": "true"` to `"false"`.
- Remove the mapping in bold below.

As a result, you should have:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)

<pre>{
    "constant": "initial",
    "targetPath": "$.passwordStatus",
    "scope": "createEntity"
},
{
    "constant": "<initial password defined by customer>",
    "targetPath": "$.password",
    "scope": "createEntity"
},
{
    "constant": "false",
    "targetPath": "$.sendMail",
    "scope": "createEntity"
},
{
    "constant": "true",
    "targetPath": "$.mailVerified",
    "scope": "createEntity"
},
// Make sure you have this target path with "constant" set to "employee".
{   "constant": "employee",
    "targetPath": "$.userType"
},
// Remove this mapping:
{
**   "constant": "39",**
**   "targetPath": "$.sourceSystem",**
**   "scope": "createEntity"**
},</pre>
	<pre>{
	    "constant": "initial",
	    "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['passwordDetails']['status']",
	    "scope": "createEntity"
	},
	{
	    "constant": "<your-initial-password>",
	    "targetPath": "$.password",
	    "scope": "createEntity",
	    "ignore": "false"
	},
	{
	    "constant": false,
	    "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sendMail']",
	    "scope": "createEntity"
	},
	{
	    "constant": true,
	    "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['mailVerified']",
	    "scope": "createEntity"
	},
	// Remove the mapping starting with "constant": "<your-source-system-type-code>", if its value is set to 39.
	// Alternatively, set "ignore" to true.
	{
	    "constant": 39,
	    "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sourceSystem']",
	    "scope": "createEntity",
	    "ignore": true
	},
	// Remove this mapping. Alternatively, set "ignore" to true.
	{
	     "constant": "<your-source-system-id>",
	     "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['sourceSystemId']",
	     "scope": "createEntity",
	     "ignore": true
	}
	// Make sure you have this target path with "constant" set to "employee".
	{
	 "constant": "employee",
	 "targetPath": "$.userType"
	},</pre>

→ Tip

If you don't want the initial password to be visible in the transformation, you can create a credential property called *initial.password* in the *Properties* section of the target system. Then, use the following substitution of the property as a mapping in the transformation:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)
`{ "constant": "%initial.password%", "targetPath": "$.password", "scope": "createEntity" }`	`{ "constant": "%initial.password%", "targetPath": "$.password", "scope": "createEntity", "ignore": "false" }`

→ Tip

If you don't want to delete the `"constant": "39"` section from the transformation, you can configure the Corporate User Store in the administration console for SAP Cloud Identity Services so as to reuse the corporate passwords. To learn how, see: Corporate User Store

Related information: Identity Authentication

Passwords Are Stored in Identity Authentication (activation e-mail)

This use case requires sending an activation e-mail (without verifying it). Via this e-mail, users can logon to the Identity Authentication service. They can later change their password.

Solution

Open the Identity Authentication target system transformation and modify the following JSON mappings:

- For `"$.sendMail"`, change `"constant": "false"` to **true**.
- For `"$.mailVerified"`, change `"constant": "true"` to **false**.
- Remove the mappings in bold below.

As a result, you should have:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)

<pre>{
"constant": "true",
"targetPath": "$.sendMail",
"scope": "createEntity"
},
{
"constant": "false",
"targetPath": "$.mailVerified",
"scope": "createEntity"
},
// **Remove these mappings:**
{
"constant": true,
"targetPath": "$.active"
},
{
"constant": "enabled",
"targetPath": "$.passwordStatus",
"scope": "createEntity"
},
{
"constant": "39",
"targetPath": "$.sourceSystem",
"scope": "createEntity"
}, */</pre>
	<pre>{
	"constant": true,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sendMail']",
	"scope": "createEntity"
	},
	{
	"constant": false,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['mailVerified']",
	"scope": "createEntity"
	},
	// **Remove these mappings:**
	{
	"constant": true,
	"targetPath": "$.active"
	},
	{
	"constant": "enabled",
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['passwordDetails']
	['status']",
	"scope": "createEntity"
	},
	// Remove the mapping starting with
	"constant": "<your-source-system-type-code>", if its value is set to *39*.
	// Alternatively, set "ignore" to *true*.
	{
	"constant": **39**,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sourceSystem']",
	"scope": "createEntity",
	"ignore": **true**
	},
	// Remove this mapping.
	Alternatively, set "ignore" to *true*.
	{
	"constant": "<your-source-system-
	id>",
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extensi
	on:sap:2.0:User']['sourceSystemId']",
	"scope": "createEntity",
	"ignore": **true**
	}</pre>

→ Tip

If you don't want to delete the `"constant": "39"` section from the transformation, you can configure the Corporate User Store in the administration console for SAP Cloud Identity Services so as to reuse the corporate passwords. To learn how, see: Corporate User Store

Related information: Identity Authentication

Passwords are Migrated from SAP SuccessFactors

Problem

1. You have SAP SuccessFactors (SFSF) as a source system and Identity Authentication as a target system.
2. You have configured your *SFSF* application so as to migrate user passwords to the administration console for SAP Cloud Identity Services, as described on Configure Authentication Provider To Migrate User Passwords from SAP SuccessFactors Systems to Identity Authentication.
3. You might have **missed** to make the additional transformation modifications, and then you have run your first provisioning job between SFSF and Identity Authentication.
4. The provisioning job is successful but the migrated passwords of SFSF users are disabled in Identity Authentication, thus users cannot login to the administration console for SAP Cloud Identity Services.

The reason: In the Identity Authentication target transformation, the `“passwordStatus”` mapping has been left with its default value - `"disabled"`.

Solution

1. You have properly configured your SFSF source system so as to migrate user passwords to Identity Authentication. To learn how, see: Configure Source System To Migrate User Passwords from SAP SuccessFactors Systems to Identity Authentication
   Migrating Passwords from SAP SuccessFactors to the SAP Cloud Identity Services
2. Make sure you have done the following modifications in the Identity Authentication transformation:
   - You have added two extra mappings with constants `<SF_Company_ID>` and *100* (see the code block below).
   - You have removed the `"constant": "39"` mapping.
   - For the `passwordStatus` mapping, you have changed `"disabled"` to `"enabled"`
3. To fix your issue, you also need to remove the `"createEntity"` scope from the `passwordStatus` mapping!
   So, after you have done the modifications listed above, your Identity Authentication transformation should look like this:

   Explanation:

   This way, on the next provisioning jobs, the Identity Provisioning will always update the password status of the users, even if they get locked in Identity Authentication. Also, the migrated passwords will be set first in Identity Authentication when a user logs in for the first time to one of their assigned applications (like SAP SuccessFactors or *User Profile*).

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)

<pre>{
"constant": "<SF_Company_ID>",
"targetPath": "$.sourceSystemId"
},
{
"constant": "100",
"targetPath": "$.sourceSystem"
},
{
"constant": "enabled",
"targetPath": "$.passwordStatus"
 	
},
{
"constant": "false",
"targetPath": "$.sendMail",
"scope": "createEntity"
},
{
"constant": "true",
"targetPath": "$.mailVerified",
"scope": "createEntity"
},</pre>
	<pre>{
	"constant": "<SF_Company_ID>",
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extens
	ion:sap:2.0:User']
	['sourceSystemId']",
	"scope": "createEntity",
	"ignore": false
	},
	{
	"constant": 100,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extens
	ion:sap:2.0:User']['sourceSystem']",
	"scope": "createEntity",
	"ignore": false
	},
	{
	"constant": "enabled",
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extens
	ion:sap:2.0:User']['passwordDetails']
	['status']"
	
	},
	{
	"constant": false,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extens
	ion:sap:2.0:User']['sendMail']",
	"scope": "createEntity"
	},
	{
	"constant": true,
	"targetPath": "$
	['urn:ietf:params:scim:schemas:extens
	ion:sap:2.0:User']['mailVerified']",
	"scope": "createEntity"
	},</pre>

4. Run a successful **Read** job.
5. Make sure that SFSF users can now successfully login to the administration console for SAP Cloud Identity Services.
6. Then open the Identity Authentication transformation again, and add `"scope": "createEntity"` back to the `passwordStatus` mapping. This way, newly created users will get their password status set by the Identity Provisioning. And since this status stays *"enabled"*, their passwords won't be locked.

Additional Information

Another (more simple) way to have all users provisioned and their passwords - successfully migrated to Identity Authentication, is to delete all SFSF users from Identity Authentication, and recreate them again. Also, you might need to change the value of the `sf.user.filter` property so as to read only SFSF users who have already existed in Identity Authentication and have *Administrator* role there. This way, the admin users will be kept and all the other SFSF users will be deleted from Identity Authentication.

> ⚠ Caution
>
> You must perform the user deletion via the Identity Provisioning service! If you delete them manually from Identity Authentication, the Identity Provisioning will still "remember" that these users were previously

created by it, thus - will have marked them with a flag that would not allow their passwords to be migrated. **Password migration can happen only during user creation via an Identity Provisioning job!**

To learn more, see:Identity Authentication: Provisioned Users Are Duplicated in SAP Jam or SAP Work Zone [page 3095]

Recreate users that have been provisioned with disabled passwords

Problem

You have provisioned users from a source system to Identity Authentication. When users try to login to the administration console for SAP Cloud Identity Services though, they cannot do that because their passwords are locked.

The reason for that is improper transformation mappings, which have caused users to be provisioned with password status *"disabled"*.

Solution

A simple solution would be to delete all provisioned users from Identity Authentication and re-create them again, this time - with active passwords. You can do that via an Identity Provisioning job, and changing the value of the user filter property, so as to read only users who have already existed in Identity Authentication and have *Administrator* role there. To do that, proceed as follows:

1. Open your Identity Authentication target transformation.
2. Search for the `"user"` mapping below and change `"disabled"` to **`"enabled"`**:

Identity Authentication (SCIM API version 1)	Identity Authentication (SCIM API version 2)
`{ "constant": "disabled", "targetPath": "$.passwordStatus", "scope": "createEntity" },`	`{ "constant": "disabled", "targetPath": "$['urn:ietf:params:scim:schemas:extension:sap:2.0:User']['passwordDetails']['status']", "scope": "createEntity" },`

3. Go to the source system and change the user filter so as to read only users who have already existed in Identity Authentication and have *Administrator* role there.
   For example, if you have an SAP SuccessFactors (SFSF) source system, go to the `sf.user.filter` property and extend its value to: `status eq 'active' and username in '<username1>','<username2>',...`
   This way, the Identity Authentication admin users will be kept, and all the other SFSF users will be deleted from Identity Authentication.
4. Run a successful **Read** job. It will delete all users that **Identity Provisioning** has previously created and that are not in the filter list.
5. Open the user filter property again and change it back to its default value. For example, change the `sf.user.filter` value back to: `status eq 'active'`
6. Run a successful **Read** job again to have all the SFSF users re-created.

Check if users can now perform their first login using their source system passwords.

Identity Authentication: Provisioned Users Are Duplicated in SAP Jam or SAP Work Zone

Problem

You have executed direct user provisioning from the administration console for SAP Cloud Identity Services to SAP Jam.

Then you go to the administration console for SAP Cloud Identity Services, set up Identity Authentication as a source system, and SAP Jam Collaboration as a target system, and run a job.

As a result, multiple users are created twice (duplicated) in SAP Jam.

The same issue may happen when the target system is SAP Work Zone. In this case, you can use the same solution here.

Reason

- When provisioned from Identity Authentication to SAP Jam via Identity Authentication console, a user `id` in Identity Authentication is mapped to a `userName` in SAP Jam.
- When provisioned from Identity Authentication to SAP Jam via IPS console, an `userName` in Identity Authentication is mapped to a `userName` in SAP Jam.

As a result, one and the same user can be created twice in SAP Jam - by its `id`, and by its `userName`.

1. Stop provisioning users to SAP Jam from the administration console for SAP Cloud Identity Services. See: Configure SAP Jam Target Systems for User Provisioning
2. Then navigate to the *Identity Provisioning* > *Target Systems*.
3. Open your SAP Jam Collaboration target system and modify its transformation removing the following two mappings:

```
{
             "sourceVariable": "entityIdTargetSystem",
             "targetPath": "$.id",
             "scope": "deleteEntity"
         },
        {
             "constant": false,
             "targetPath": "$.active",
             "scope": "deleteEntity"
        },
```

4. Now open your Identity Authentication source system and reset it. To do that, select the system and choose *Edit* > *Reset*.
5. Then modify the Identity Authentication transformation the following way:
   Change this mapping:

```
{
     "sourcePath": "$.userName",
     "optional": true,
     "targetPath": "$.userName",
     "correlationAttribute": true
  }
```

   To:

```
{
     "sourcePath": "$.id",
```

```
    "targetPath": "$.userName",
    "correlationAttribute": true
  }
```

6. Run a **Read** job for the Identity Authentication system. All entities created before directly from the Identity Authentication console to SAP JAM will be updated in SAP JAM. This way, the Identity Provisioning already knows about these entities and can manage them. Entities created from provisioning through the administration console for SAP Cloud Identity Services will remain.
7. Go to the SAP Jam target system, and add the following (Standard) system property: `ips.delete.existedbefore.entities` = **`true`**
8. Now go back to the Identity Authentication source system and add a special condition in the `"user"` section. Your mapping should look like this:

```
"user":
 {
  "condition": "($.name.familyName EMPTY false) && ($.name.familyName ==
'DUMMY_NAME')",
"mappings": [
```

9. Run a new **Read** job for the Identity Authentication system. At this step, all users provisioned through Identity Authentication console should be deleted from SAP JAM.
10. Now go to the SAP Jam target system and return the mappings you have removed on step 3.
11. Then go back to the Identity Authentication source system and delete the condition from step 8.

Next steps

From now on, use only the administration console for SAP Cloud Identity Services for provisioning users (and groups) from Identity Authentication to SAP Jam. All future *Read/Resync* jobs will provision your users correctly, mapping `userName` to `userName`, without duplicating entities anymore.

Identity Authentication: Some Additional Users Should Not Be Provisioned to SAP Jam

Problem

1. You have an SAP Jam product, which contains Identity Authentication and Identity Provisioning.
2. When your product is activated, all users from Identity Authentication are initially provisioned to SAP Jam, which is a default and desired behavior.
3. Later on, additional users were added to Identity Authentication (either created manually, or come from another product).
4. All these new users are automatically provisioned to SAP Jam too, but some of them **should not be**.

Reason

The default SAP Jam transformation is set so as to be synchronized with all changes that take place in the source system (Identity Authentication). That means - both updating existing users, or creating newly added ones.

However, you want some of these users to stay only in Identity Authentication and not to be provisioned to SAP Jam. For example, specific users coming from another products.

Solution 1

You can set a filter that will read, create and update only **"pure Identity Authentication"** users (originally existing in Identity Authentication, or manually created later).

1. You have to assign all these Identity Authentication users to a specific group. Let's say, the group name is called **`IAS_Specific`**.
2. All additional users (coming from other products) must belong to other groups or to no groups at all.
3. To set a filter, open your SAP Jam target system.
4. Go to the *Properties* tab and choose *Edit*.
5. Add property `scim.user.filter` and set its value to **`groups eq 'IAS_Specific'`**

This way, if a new user appears in Identity Authentication, and it doesn't belong to *IAS_Specific*, it will not be provisioned to SAP Jam.

Solution 2

If it's too complicated or cumbersome to assign all **"pure Identity Authentication"** users to a single group, you can instead assign the newly come **foreign** users to a specific group. Then, you can set a condition in the transformation so as to skip only this specific group.

1. Let's say, the **foreign** users come from SAP Marketing Cloud, so you assign the relevant users to a group named **`Marketing_Cloud`**.
2. To set a condition, open your Identity Authentication source system.
3. Go to the *Transformations* tab and choose *Edit*.
4. Under `"user":{` enter the following condition:

```
{
   "user": {
       "condition": "$.groups EMPTY true || $.groups[?(@.value ==
'Marketing_Cloud' )] == []",
       "mappings": [
       {
           "sourcePath": "$.id",
           "targetVariable": "entityIdSourceSystem"
       },
. . .
```

This way, the Identity Provisioning service:

- Will provision all users that don't belong to any groups.
- Will **not** provision anything from group *Marketing_Cloud*.
- Will provision all users that belong to any group different than *Marketing_Cloud*.

See also: Identity Authentication: Provisioned Users Are Duplicated in SAP Jam or SAP Work Zone [page 3095]

Identity Authentication: Send activation email in users preferred language

When provisioning users from SAP SuccessFactors to Identity Authentication, you want the newly created users in Identity Authentication to get the activation emails in their preferred language. For this, you need to configure the transformations of both SAP SuccessFactors (source) and Identity Authentication (target) systems.

Proceed as follows:

1. In your SAP SuccessFactors system, select the *Transformations* tab and add one of the following transformation codes in the user mapping section:

Use `preferredLanguage` attribute	Use `defaultLocale` attribute
`{ "sourcePath": "$.preferredLanguage", "optional": true, "targetPath": "$.locale" },`	`{ "sourcePath": "$.defaultLocale", "optional": true, "targetPath": "$.locale" },`

   Normally, `defaultLocale` is used for onboardees (new hires). If a user in SAP SuccessFactors does not have the `defaultLocale` attribute filled in as desired, you can set it by following the procedure described in KBA: 2395445 - Default Locale | How to control the user language in SuccessFactors
   For more information, see: Configuring Email Templates

2. Select the *Properties* tab and append the attribute of your choice (`preferredLanguage` or `defaultLocale`) to the already listed attributes in the value field of the `sf.user.attributes` property.
3. Save your changes.
4. In your Identity Authentication target system, select the *Transformations* tab and add the following transformation code in the user mapping section for `"locale"`:

```
{
   "sourcePath":"$.locale",
   "optional":true,
   "targetPath":"$.locale",
   "functions":[
   {
      "function":"toUpperCaseString"
   },
   {
      "function":"substring",
      "beginIndex":0,
      "endIndex":"2"
   }
  ]
},
```

   This is needed because language formats differ in SAP SuccessFactors and Identity Authentication.
   For more information, see: 2269945 - List of Supported Languages with Locales for SuccessFactors
5. Save your changes.
6. Run a provisioning job in SAP SuccessFactors source system.
7. Verify that the newly created users in Identity Authentication receive the activation emails in their preferred language.

For other solutions on how to send welcome e-mails in a predefined language, see SAP KBA 3035482

Job Is Successful but Statistics Are Missing

Problem

1. You've added a source and a target system in your administration console for SAP Cloud Identity Services.
2. You've started a provisioning job (*Read* or *Sync*).
3. In the *Job Logs* section, you see that the job has finished successfully. However, the *Statistics* table is empty.

Reason	Solution
You have set a filter in the *Properties* tab that does not match any of the entities in the system.	Change the filter so that it matches at least one entity.
No changes have been made in the source system since the last provisioning job.	You'll see the statistics if you change at least one entity in the source system, and then run a new job.
Your source system is SAP SuccessFactors, and the technical user is missing *Export* permissions to read employee data from the SAP SuccessFactors system.	Obtain *Export* permissions for SAP SuccessFactors. To learn how, see: Permissions.

Microsoft AD: Nested Groups Are Not Resolved in the Target System

Problem

Your source system is Microsoft Active Directory and you want to provision all users and groups, along with all group members. However, some of the groups contain "nested" subgroups. All these groups and subgroups contain users.

When the provisioning job is done, in the target system only the direct members of the parent group are provisioned. The user assignments from all subgroups are missing.

Reason

Some target systems don't support nested groups (group structures). Such target systems are:

- SAP Jam Collaboration
- Identity Authentication

Therefore, if you provision group structures to one of these target system types, the user assignments from the subgroups will be missing.

Solution

Luckily, you can enable recursive reading of such group structures. All you need is to set the following two properties:

- `ad.group.flatten` = **`true`**
- `ldap.group.filter` = **`(cn=<parent_group>)`**

As a result, in the target system all users will be written in one parent group, which has the same name as the source parent group.

Example

- Let's say, in your Microsoft AD system there is a parent group *"Canteen"* that contains nested subgroups. If you set `ldap.group.filter` = **`(cn=Canteen)`**, the Identity Provisioning will resolve all the direct users and groups of *"Canteen"*, along with all the users of its subgroups (and their subgroups). In the target system, all users will be written in one parent group named also *"Canteen"*.
- If you have multiple parent groups (for example, *Canteen*, *Finances* and *Support_Team*) that contain nested subgroups, you can set the filter property like this:

```
ldap.group.filter = (|(cn=Canteen)(cn=Finance)(cn=Support_Team))
```

Microsoft Azure: Emails Are Missing

Problem

When you add Microsoft Active Director as a source system and you run a provisioning job, some of the populated users in the target system have missing e-mail addresses. This issue can be a provisioning blocker for target systems that require a mail attribute (for example, Identity Authentication).

Reason

> **Note**
>
> The image/data used is from SAP internal systems, sample data, or demo systems. Any resemblance to real data is purely coincidental.

There can be two reasons for such a behavior:

- Some users don't have a Microsoft Office 365 license.
- They have this license but their `mail` attribute is not tied to Microsoft Exchange Online, which leads to lack of synchronization between user data on the on-premise Microsoft AD and Azure AD.

In both cases, after the provisioning job, the value of the user's emails attribute in both the source and the target system is *null*. For example:

User details in the source system	User details in the target system

`"displayName": "Johnny123",`
`"givenName": "John",`
`"surname": "Smith",`
`"mail": "null",`
`"userPrincipalName":`
`"JohnSmith",`
`...`
	`"displayName": "Johnny123",`
	`"givenName": "John",`
	`"familyName": "Smith",`
	`"emails": null,`
	`"userName": "JohnSmith",`
	`...`

Solution

You need to map the user e-mail to another attribute, for example `userPrincipalName`. In the source transformation, modify the following JSON lines:

```
/* Remove this part:
    {
        "sourcePath": "$.mail",
```

```
        "targetPath": "$.emails[0].value"
    }, */
// Change the following part to:
    }
        "sourcePath": "$.userPrincipalName",
        "targetPath": "$.emails[0].value"
    },
    {
        "sourcePath": "$.displayName",
        "optional": true,
        "targetPath": "$.displayName"
    },
...
```

Result

User details in the target system (after modifying the transformation):

```
"displayName": "Johnny123",
"givenName": "John",
"familyName": "Smith",
"emails": null,
"userName": "john.smith@acme.com",
...
```

Multiple Users from a Source System Are Created as One in the Target

The problem described on this page illustrates a scenario involving SAP SuccessFactors (SFSF) as a source system and Identity Authentication as a target one. However, this issue may occur to any source system while provisioning users to the following targets:

- Identity Authentication
- SAP Analytics Cloud
- SAP Datasphere

> **Note**
>
> The problem will happen only if you use *email* as a unique attribute in the target.
>
> If you have modified the *email* to **NOT** be unique (for example - in Identity Authentication), **ignore this section!**

Problem

1. You've added SAP SuccessFactors as a source system and Identity Authentication as a target one.
2. You haven't set any specific filters. Thus, the provisioned users are expected to be the same number as the ones in SFSF..
3. You've started a **Read Job**, which finishes successfully.
4. When you check the populated entities, though, you notice that the users created in Identity Authentication are fewer (or significantly fewer) than the original number of users in SFSF.

Reason

The user e-mail is optional for SFSF (it might not be unique). However, it's mandatory and unique for Identity Authentication.

Therefore, it's very likely that some users have **duplicate** e-mail addresses in SFSF, which causes the improper provisioning. The Identity Provisioning service stores a **relation** for every source entity and its corresponding target entity. When multiple users have duplicate e-mails and the provisioning is triggered, the stored relation is "**many** source entities that point to **a single** target entity".

> → Remember
>
> Before you start provisioning SFSF users to Identity Authentication for the first time, make sure that all users **have** e-mails, which are **unique**, even if these entities are only meant for test purposes. This way, you won't encounter the problem described in this guided answer.

Prerequisites

To solve the occurred problem, you first need to edit the e-mails of all affected SFSF users. You can do this in two ways - manually or programmatically.

- Manually
  Edit the e-mail of each affected user in SFSF.
- Programmatically
  You have to modify the SF source system transformation so as to create a unique e-mail address for each conflicting user during the next **Read** Job.
  - If you use SFSF source system with SAP SuccessFactors Workforce SCIM API (SF API version 2), follow the procedure in KBA: 3308246
  - If you use SFSF source system with SAP SuccessFactors HCM Suite OData API (SF API version 1), follow the procedure below:
    To do this, enhance the default email mapping:

```
{
  "sourcePath": "$.email",
    "targetPath": "$.emails[0].value"
 },
```

    to:

```
{
   "sourcePath": "$.email",
   "optional": true,
   "targetPath": "$.emails[0].value"
},
{
   "condition": "!($.email EMPTY false) || $.email == '' || $.email == ' '
|| $.email == 'user123@companyname.com' ",
   "sourcePath": "$.userId",
   "targetPath": "$.emails[0].value",
   "functions": [
      {
        "type": "concatString",
        "suffix": "@sap-test.de"
      }]
}
```

    What does the condition above mean?

- `$.email == !($.email EMPTY false)` means that the user lacks an email attribute.
- `$.email == ''` means the SFSF user has no business e-mail set.
- `$.email == ' '` means the SFSF user has a space character set as an e-mail address.
- `$.email == 'user123@companyname.com'` means that multiple users in SFSF have a business e-mail *user123@companyname.com*, which results in errors in the Identity Authentication target system. This email address is just an example! In your condition, the listed emails can refer to your actual company domain, or to another non-existing one.

> ### Note
>
> **@sap-test.de** is the recommended test domain approved by SAP for customer dummy (testing) requests. Thus, please use only this one for the *concatString* function! If you use another non-existing domain, it might get blocked for security reasons.

> ### Note
>
> Bare in mind that the condition is case sensitive! Thus, make sure that all SFSF e-mails contain low-case letters only. If some of them contain capital letters, you can either go and manually change them to low case, or list all emails like that in the condition.

Using the code above, each provisioned user will be created in Identity Authentication with a unique e-mail in format **`<userId>@sap-test.de`**. Users that have valid unique business e-mails set in SFSF will be provisioned with the same valid e-mails in the administration console for SAP Cloud Identity Services.

Solution

After you have executed the prerequisite steps, follow the final steps below:

1. Reset the Identity Authentication target system. To do this, select the system and choose *Edit* > *Reset*. This way, all previous entity relations will be deleted. System configurations and all existing provisioned entities, along with their authorizations, will be preserved.
2. In the *Properties* tab, add a standard property `ips.delete.existedbefore.entities` and set it to *true*. This property provides correct behavior if a user is later deleted from SFSF. If this happens, during the next **Read/Resync** Job, the Identity Provisioning will recognize this user as **"existed before but now deleted from the source system"** and will delete it from the target system as well. To learn more, see List of Properties.
3. Add a standard property `scim.user.unique.attribute` and set it to **`userName`**. This way, if the Identity Provisioning reads two different users with the same e-mail, it will try to resolve the second one by *user name*. Since these two users have different user names, this second entity will fail with an error for duplicate e-mail. You will see it in the *Job Logs*. This approach is safe because it won't affect the successfully created users in the target system, and will only prompt you to edit the SFSF e-mails of newly added conflicting users.
4. Now open the SAP SuccessFactors source system.
5. Start a new **Read** Job.
6. As a result, all source entities will be read and then created/updated in the Identity Authentication target system. The Identity Provisioning will store a new unique relation between each source entity and its corresponding target entity.

Provisioning Jobs Take Extremely Long Time

Problem

1. You have added a source and a target system in your administration console for SAP Cloud Identity Services.
2. You start a **Resync** job.
3. The job is taking an extremely long time to execute, even if it finishes successfully.

Reasons

There can be a few reasons for such a behavior, depending on your type of system, or the location of your business applications and the data centers where your tenants reside.

Choose the option that applies to your scenario:

Your source system is SAP SuccessFactors, SuccessFactors LMS, Microsoft AD, or Identity Authentication

- **Overview Information**
  Your source system type is one of the following:
  - SAP SuccessFactors
  - Microsoft Active Directory
  - SAP Cloud Identity Authentication

  These three systems support **delta read** provisioning.
  Delta read is a concept for optimizing the amount of data retrieved from the source system. Delta read is much faster than **full read** as only modified data is read from the source system and triggered to the target one. Modified data means: new entities, deleted entities, and updates on existing entities. This is useful when you schedule the read jobs. For example, every 10th job can be a full read, and the rest will be delta read jobs, which can significantly improve the execution time of the provisioning job.

SAP SuccessFactors **SAP SuccessFactors LMS**	By default, delta read is **enabled** for these systems. That means, the first ever **Read** job will be a full one, meaning - reading all source entities. If it's successful and you have set schedule jobs to be executed on a certain time interval, the next executed job will be a **delta** one (reading only modified data).
Microsoft Active Directory **SAP Cloud Identity Authentication**	By default, delta read is **disabled** for these systems. That means, the first ever **Read** job will be a full one, meaning - reading all source entities. If it's successful and you have set schedule jobs to be executed on a certain time interval, the next executed job will be again a **full** one (reading again everything from the source system). To activate delta read, go to the *Properties* tab, and set the following property: `ips.delta.read=enabled`

- **Possible Reason**
  Instead of **Read**, you might have run a **Resync** job. What's the difference?
  - A **Read** job will read all users, but provision only the **delta** to the target systems. That means, only newly created, updated, or deleted users in the source system be respectively created, updated, or

deleted in the target systems by the Identity Provisioning service. When the first full provisioning is successful, the next read jobs will work in **delta read** mode.

- A **Resync** job would read all users from the source system (based on the configured filter), and provision all of them to the target system, even if previous provisioning job already did this and most of the users have not changed since the previous job. It is like executing a provisioning job for the first time. If some users were already provisioned before, the Identity Provisioning service will perform update for them.
  In addition, if the users are already present in the target systems by other means, and not from an Identity Provisioning job, the service will try to create them - which operation would fail - and then the service will fetch every user from the target and update it. This additional operation could further slow down the job execution.

Recommendation:
We recommend that you use a **Resync** job when manual changes have been made in the target systems, which the Identity Provisioning is unaware of. In this case, the service can sync all users data from the source to the target with a **Resync** job. In all other cases, it is sufficient to execute **Read** jobs only.
Solution
Next time, manually execute a **Read** job. Make sure the delta read is set for your system!
If the result is sufficient to you, you can schedule your read jobs in order to be automatically executed on a certain period of time.
Recommendation:
We recommend that you enforce full reads once in a while if your provisioning system is set in **delta read** mode. To achieve this, you need to set up the following source system property like, for example:
`ips.full.read.force.count=10`
This will result in alternating full reads after every **10 delta reads** are performed. This property only impacts scheduled runs. Manually triggered runs are ignored.

Your Source System is of Another Type

Reason

Your source and target business applications are placed in one location, and the data center where your SAP Cloud Identity Services tenant resides is in a very distant region.

For example, your SAP Cloud Identity Services tenant is located in Europe, while your business application instances are located in the US. This makes the connection between the system significantly slower.

Solution

- Migrate your tenants, or request new ones.

  > ### Note
  >
  > The provided solution is only applicable to **bundle tenants**!

- You can migrate your SAP Cloud Identity Services tenant to another data center - where your source system is. To request that change, create an incident to component **BC-IAM-IDS**. You will receive details about the procedure, or you can request a new SAP Cloud Identity Services tenant to be created in the region where your source system is.
- Currently you cannot migrate your SAP Cloud Identity Services tenants. But you can request a new one for the region where your source system is. The old SAP Cloud Identity Services tenant can be deleted or preserved - depending on whether you will need it in future for business applications whose instances are located in the initial region. To request that change, create an incident to component BC-IAM-IPS.

Provisioning Job Fails for One of Multiple Target Systems

Problem

1. You added one source and multiple target systems in your administration console for SAP Cloud Identity Services.
2. You started a provisioning job.
3. The job fails for one of the multiple target systems.

Reason

Provisioning to one of the target systems may fail due to exception.

Provisioning Job Fails with Exception

Problem

1. You added one source and multiple target systems in your administration console for SAP Cloud Identity Services.
2. You started a provisioning job.
3. The job fails with one of the following exceptions:

- *Caused by: Timeout exception has occurred while processing entity for <URL of the source system>*
- *Caused by: Timeout exception occurred*

Reason

Those exceptions occur when provisioning to one of the multiple target systems fails, for example, due to connectivity issues.

Solution

Start the provisioning job again.

Not All Users are Provisioned to the Target Systems

Problem

1. You added one source and multiple target systems in your administration console for SAP Cloud Identity Services.
2. You started a provisioning job.
3. You get one of the following results and you want to know why:
    - Not all users are read from the source system, and yet, their number is greater than the number of users provisioned to the target system.
    - All users are read from the source system but less are provisioned to the target system.

Reasons

Possible reasons when **not all users** are read from the source system, and yet, their number is greater than the number of users provisioned to the target system.

- There are inactive users in the source system. Identity Provisioning only provisions active users.

- Provisioning job is run in delta read mode.
- Connection to the source system fails.

Possible reasons when **all users** are read from the source system but less are provisioned to the target system:

- Provisioning to one of the multiple target systems has failed. See: Provisioning Job Fails for One of Multiple Target Systems [page 3106]
- A full Read job has been run. After that, there were no changes on users in the source system. Next run of a full Read job reads all users from the source system but provisions "0" users to the target due to lack of changes.

Provisioning Job Fails for One of Multiple Target Systems

Problem

1. You added one source and multiple target systems in your administration console for SAP Cloud Identity Services.
2. You started a provisioning job.
3. The job fails for one of the multiple target systems.

Reason

Provisioning to one of the target systems may fail due to exception. See: Provisioning Job Fails with Exception [page 3116]

Scheduled Jobs Are Not Running

Problem

1. In the administration console for SAP Cloud Identity Services, add a source and a target system.
2. Open the source system, then the *Jobs* tab.
3. Choose *Schedule* and enter a number (of minutes).
4. Choose *OK* and wait for a while.
5. Open *Job Logs* to check the job's status. However, you don't even see the job, which means it's not started yet.
6. No matter how long you wait, the job does not appear on the screen.

Solution

After you've set up a schedule job, you must always choose the **On** button to actually start the job. This is a one-time manual step.

Once you've selected *On*, the job starts automatically, according to the predefined period of time.

I Still Have Problems with Job Scheduling

Your problem requires deeper analysis by SAP. Please create an incident for component BC-IAM-IPS.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

SAP IBP: Avoid Restoring Decimal Format, Time Zone and Language to Their Defaults

When updating a user in SAP Integrated Business Planning (or any other SAP S/4HANA Cloud Public Edition-based system), you want to make sure that only specified attribute values are updated, while others remain unchanged.

> **Note**
>
> In addition to SAP IBP, this troubleshooting information is also applicable to SAP S/4HANA Cloud Public Edition, SAP BTP ABAP environment , SAP Marketing Cloud and SAP Market Communication for Utilities.

Problem & Reason

Currently, if a user is created in SAP IBP target system and later on you update the user without providing values for attributes in the User node (such as, decimal format, time zone and language), these values are restored to their defaults.

To reproduce this behavior, proceed as follows:

1. Run a provisioning job from a source system (for example, Identity Authentication) to SAP IBP. Users are created with the default values:
   - **Decimal Format**: 1.234.567,89
   - **Time Zone**: No value
   - **Language**: English United States
2. In SAP IBP, modify the attributes of a given user:
   - Change the **Decimal Format**, for example to **`1,234,567.89`**
   - Select a **Time Zone**, for example **`Eastern Europe`**.
   - Leave the English United States **Language** as-is or change it.
3. In Identity Authentication, update the user, for example change its last name only.
4. In Identity Provisioning, run a provisioning job.
   As a result, the user's last name in SAP IBP is updated. Since no values are provided for decimal format, time zone and language, in SAP IBP expect the following:
   - **Time Zone and Decimal Format** are restored to their default values.
   - **Language** is removed.

Solution

To ensure that only specified attribute values are updated, while others remain unchanged, you need to modify the SAP IBP target transformation.

1. Add the bolded attribute mapping at the end of the user entity as follows:

```
{
                "condition": "$.active == false",
                "constant": "true",
                "targetPath": "$.user.lockedIndicator"
            },
        {
                "constant": "02",
                "targetPath": "$.user.actionCode"
            },
            {
                "constant": "01",
                "targetPath": "$.user.actionCode",
                "scope": "createEntity"
            }
        ]
    },
```

   - `"constant": "02"`
     This means that Action code 02 (representing update operation) is applied for attributes in the User node.
   - `"constant": "01"`
     This means that Action code 01 (representing create operation) is applied for attributes in the User node. The scope of this mapping is createEntity, which means that the entity attribute is only processed during creation.
2. Modify some user's attributes and run a provisioning job.

As a result, only the specified attribute values are updated. Others for which no value is provided remain unchanged.

SAP SuccessFactors: Some Entities are Unexpectedly Deleted from Target System

Problem

1. You set SAP SuccessFactors as a source system and have enabled **delta read** for it.
2. You set a target system (any kind).
3. You have been running manual or scheduled jobs for some time. When a job finishes with an error, you have noticed that no entities have been deleted.
4. If you run a new job after **October 1, 2020**, you see that some or many entities are unexpectedly deleted.

Reason

Expected behavior:

If a provisioning job has successfully read all entities from a source system (with **delta read** enabled) but fails due to problems with provisioning of some entities, the entities that have to be deleted **should be deleted**.

Actual behavior before October 1, 2020

Entities that should have been deleted were **not deleted** during delta read. This behavior was incorrect but is now fixed.

> **Note**
>
> If a provisioning job was successful, this problem would not have been observed. Read entities were created/updated, and unread entities were deleted from the target.

Solution

Effective **October 1, 2020** this bug has been fixed in the Identity Provisioning service, and now the default behavior happens. That's why you observe "unusual deletion" of entities in your target system, which is how it's supposed to be.

Related Information

If you want the service to read only part of the entities in your source system but to **save** the unread ones from deletion in the target, see: Entities Should Not Be Deleted in the Target System [page 3080]

Users Are Not Being Assigned to Groups in the Target System

Problem:

After running a provisioning job, some users are not assigned to groups in the target system.

Reason:

By default, Identity Provisioning provisions users and groups separately in one job. User assignments are provisioned as part of the group membership.

Identity Provisioning cannot assign a user to a group if:

- The user failed or was skipped during provisioning.
- The user was not read from the source system.

This applies even if the user already exists in the target system (for example, created manually).

Solution:

To ensure users are assigned to groups:

- Verify that all users are successfully provisioned by Identity Provisioning.
- Check the job logs for failed or skipped users. If issues exist, follow Manage Provisioning Job Logs [page 3010] to identify the reason for failures and download error logs and skipped entity logs for the job.

Entity Deletion Issues [page 3121]

Additional Information [page 3130]
Handling Specific Attributes [page 3137]

1.12.15.3 Error Messages

[Job Logs] Error statusCode: 401

Problem

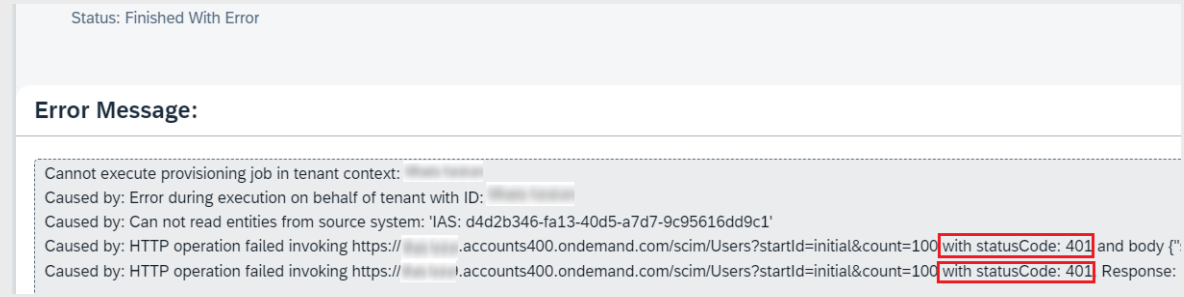
1. You added a source and a target system in the administration console for SAP Cloud Identity Services.
2. You started a provisioning job (**Read** or **Resync**).
3. In the *Job Logs* section, you see that the job has finished with error.
4. You find an error with status code **401** - either in the main *Error Message* filed, or in the details of a particular failed entity.

The error looks similar to the following ones:

- In the main *Error Message* field, you find: *"HTTP operation failed invoking <system_URL> with statusCode: 401"*
- In the logs of a failed entity, you find: *"OAuth request failed with status: 401 and body: {"error":"unauthorized","error":"description":"Bad credentials"}"*

Example

1



Example

2

Reason

This error mostly appears when the credentials of the relevant system are wrong. However, the reason can also be incorrect names or values of the following properties:

- `Authentication` (*BasicAuthentication*, *NoAuthentication*, *ClientCertificateAuthentication*)
- `ProxyType` (*Internet*, *OnPremise*)
- `Type` (*HTTP*, *LDAP*, *RFC*)
- `URL`

> **Note**
>
> These properties and values are case-sensitive.

Bear in mind the place you've found the error! That means:

- If the **401** error appears in the main *Error Message* field - the wrong credentials or incorrect property values are in the source system.
- If the **401** error appears in the details of a failed entity - the wrong credentials or incorrect property values are in the target system.

Solution

Go to the *Properties* tab of the relevant source or target system and correct the credentials (`User` and `Password`), or the other affected properties.

Error statusCode: 432

Problem

1. You use SAP SuccessFactors as a source system, and Identity Authentication as a target one.
2. You run a provisioning job between the two systems.
3. In the administration console for SAP Cloud Identity Services you see that all users have been successfully created or updated.
4. Nevertheless, in the *Job Logs* statistics, the job has finished with error due to some failed users. You can find the following error message for the relevant users:

statusCode: 432, Response: User is provisioned to Identity Authentication but its UUID is not successfully updated back on SAP SuccessFactors.

Reason

Effective February 16, 2021, Identity Provisioning supports the SAP SuccessFactors attribute `sapGlobalUserId`. That means, your provisioning logic will be as follows:

1. You start a new Read or Resync job.
2. The Identity Provisioning service reads the users from SAP SuccessFactors and writes/updates them in Identity Authentication.
3. The Identity Authentication generates a `UUID` for each newly created user.
4. During the runtime of the same job, the service will also send a request back to SAP SuccessFactors, which aims to update all users whose `sapGlobalUserId` attribute is either *null* or already exists.

- When the value is *null* - Identity Provisioning reads the `sapGlobalUserId` attribute of every user in SAP SuccessFactors, and if for some user this attribute is missing, the service will update it with the value of the `userUUID` attribute in Identity Authentication.
- When the value already exists - Identity Provisioning updates the existing `sapGlobalUserId` attribute value of a given user with the new value. Typically, this could happen if a user is provisioned from SAP SuccessFactors to Identity Authentication and later on deleted from the target system. After running a Resync Job, the deleted user is created again in Identity Authentication. A new `userUUID` is generated for this user and Identity Provisioning updates the old value in SAP SuccessFactors.

So, if for some reason the update request to the source system fails, you will get this general *432* error code.

Reason

For your SAP SuccessFactors system, send the following REST API request:

```
https://<system_host>.successfactors.eu/odata/v2/Users/('user_D')?
$expand=personKeyNav/userAccountNav&$select=personKeyNav/userAccountNav/
sapGlobalUserId,personKeyNav/userAccountNav/accountUuid, personKeyNav/
userAccountNav/username, &$format=json
```

In addition to username, this request returns also the following specific attributes: `accountUuid` and `sapGlobalUserId`

- `accountUuid` – this attribute is used by Identity Provisioning to update the `userUuid` attribute of a user in the SAP SuccessFactors system. The value of `accountUuid` must not be *null* or invalid! Thus, make sure all users have a valid `accountUuid` value.
- `sapGlobalUserId` – this attribute stores the value of `userUuid`. Identity Provisioning will try to provision the `userUuid` if the value of `sapGlobalUserId` is *null* (missing) or if it already exists. Thus, the update of `userUuid` will be completed successfully when the `sapGlobalUserId` attribute has/gets a value, or when the old value is updated with a new one.

User 'v4admin' Causes Job Error

Problem

1. You've added SAP SuccessFactors as a source system and Identity Authentication as a target one.
2. You've started a **Read** Job, which finishes with error.
3. In the *Job Logs* section, you see that the error mentions user "*v4admin*" and contains the following error message:

Property lastModifiedDateTime is not available for {"lastName":"System","empId":null,"lastModifiedDateTime":null,...,"userId:"v4admin"...}

Reason

1. Open the SAP SuccessFactors source system and choose *Properties*.
2. Modify the `sf.user.filter` property, extending its current value by adding the following string at the end: `and userId ne 'v4admin'`
3. Save your changes.
4. Run a new Read Job.
5. The provisioning job should now finish successfully.

> ### Example
>
> If the previous value of your `sf.user.filter` property is, for example: *location eq 'US'*, then you should change it to: **`location eq 'US' and userId ne 'v4admin'`**.

Invalid Property Names: User/usersSysIdOfSecondaryAssignmentsItemNav

Problem

A provisioning job that reads users from SAP SuccessFactors fails with the following error:

*Response: {"error" : {"code" : "COE_PROPERTY_NOT_FOUND", "message" : {"lang" : "en-US", "value" : "***[COE0021]Invalid property names: User/usersSysIdOfSecondaryAssignmentsItemNav***. Please check the property name in Admin Center > OData API Data Dictionary or entity metadata. Ensure there were no data model changes that removed this field, and please execute a refresh metadata to ensure the cache is not corrupted."}}}*

Reason

The attribute `usersSysIdOfSecondaryAssignmentsItemNav` is present when options *Concurrent Employment* and *Global Assignment* are enabled in the SAP SuccessFactors system. The default Identity Provisioning configuration considers that those options are enabled.

If they are not enabled, the above mentioned error appears. To solve this problem, follow the steps below.

Solution

1. Open the administration console for SAP Cloud Identity Services and navigate to the SAP SuccessFactors source system.
2. Go to the *Properties* tab and set the following attributes:
   - `sf.user.attributes` = *userId,username,status,email,lastName,firstName,lastModifiedDateTime,personKeyNav*
   - `sf.user.attributes.expand` = *personKeyNav,personKeyNav/userAccountNav*
   - `sf.user.filter` = *status in 'active','active_external','active_external_suite'*
3. Go to the *Transformations* tab and remove the following condition from the transformation (everywhere you find it):
   `"condition": "!($.usersSysIdOfSecondaryAssignmentsItemNav.results.length() > 0)",`
4. Run a new provisioning job.

Provisioning to S4 failed: [Employee ONPREMXXXXX: Insertion or modification with errors

Problem

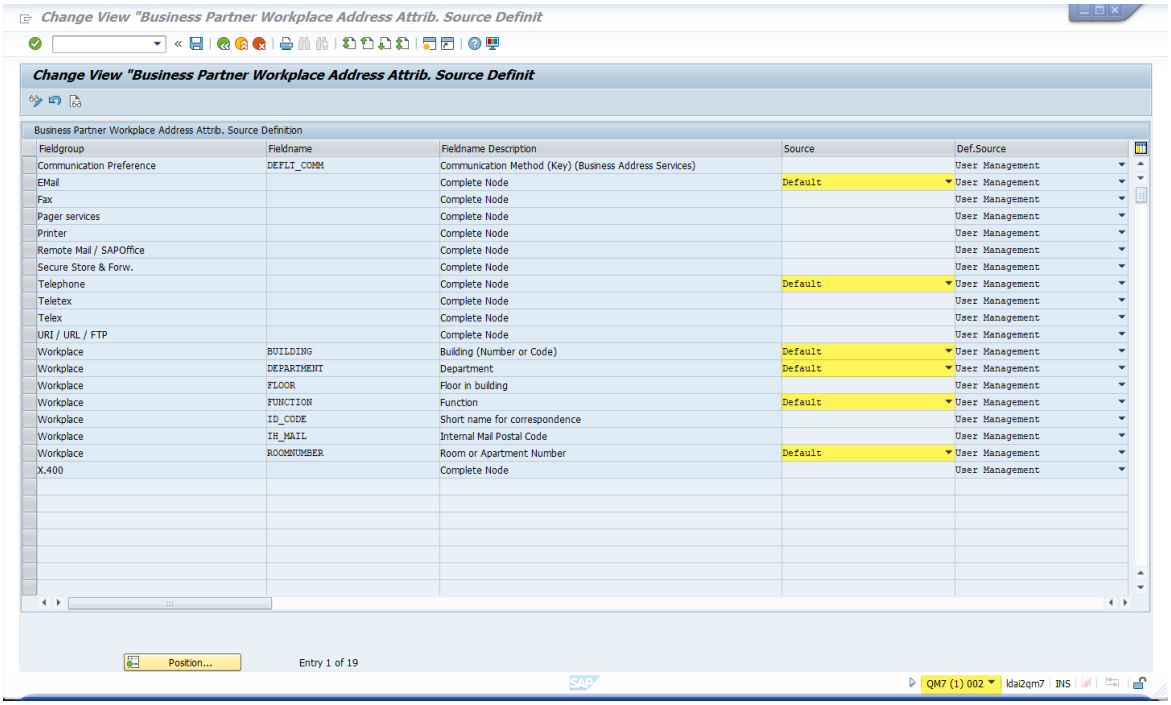
1. You configure an SAP S/4HANA on-premise system (in SAP ABAP).
2. You add a target system for it in the administration console for SAP Cloud Identity Services.

3. You add a source system and connect it to the target S/4HANA On-Premise target system.
4. Run a provisioning (Read) job.
5. The job fails with an error of type: *Provisioning to S4 failed for the following reason(s): [Employee ONPREMXXXXX: Insertion or modification with errors.]*

The error message contains one of the following reasons (or similar):
[BP 0000019334: Change of field EMAIL not permitted using data source BP], [ONPREM16772: Error while inserting / updating workplace address.],
[BP 0000019334: Change of field WORKPLACE - BUILDING not permitted using data source BP], [ONPREM16772: Error while inserting / updating workplace address.],
[BP 0000019334: Change of field WORKPLACE - FUNCTION not permitted using data source BP], [ONPREM16772: Error while inserting / updating workplace address.],
[BP 0000019334: Change of field WORKPLACE - DEPARTMENT not permitted using data source BP], [ONPREM16772: Error while inserting / updating workplace address.],
[BP 0000019334: Change of field WORKPLACE - ROOMNUMBER not permitted using data source BP], [ONPREM16772: Error while inserting / updating workplace address.],

Problem

1. Now go to your S/4HANA on-premise system and open transaction */nSPRO*.
2. Then navigate to *Cross-Application Components* > *SAP Business Partner* > *Addition Customizing for SAP Business Partners* > *Workplace Address Attribute Source Definition*.
3. (Optional) You can reach to the same place via transaction */nSM30*, and then for Table/View enter: **TBZ_V_EEWA_SRC**
4. Your table looks similar to this:



Reason

Your user attributes are of type *Default*. But they should be of type *Business Partner*.

Solution

1. You have opened the table view in *"Workplace Address Attribute Source Definition"* of your S/4HANA on-premise system.
2. Now go to column *Source*, and by the drop-down menu, change *Default* to *Business Partner*.

Provisioning Job Fails with Exception

Problem

1. You added one source and multiple target systems in the administration console for SAP Cloud Identity Services.
2. You started a provisioning job.
3. The job fails with one of the following exceptions:
   - *Caused by: Timeout exception has occurred while processing entity for <URL of the source system>*
   - *Caused by: Timeout exception occurred*

Reason

Those exceptions occur when provisioning to one of the multiple target systems fails, for example, due to connectivity issues.

Solution

Start the provisioning job again.

Provisioning Job Fails with Error Unsuccessful Provisioning of the Entity

Problem

1. You added a source and a target system in your administration console for SAP Cloud Identity Services.
2. You started a provisioning job (**Read** or **Resync**).
3. In the *Job Logs* section, you see that the job has finished with error.
   In the details of the failed entity, you find the error *"Unsuccessful provisioning of the entity"*.

Solution

Your problem requires deeper analysis by SAP. Please create an incident for component BC-IAM-IPS.

In the incident, specify also:

- The IDs of your global account and subaccount, or your bundle tenant.
- To which region your account/tenant belongs. You can find it in this list: (Discovery Center) Identity Provisioning -> *Service Plan*
- The Job log with information about the failed entity

Before you create a support case, read:

2654164 - What to consider before opening a Support Ticket for SAP Business Technology Platform

For contract-related questions, read:

1660069 - How to contact SAP Contracts Department for questions or issues

Display All Failed or Skipped Entities

Your provisioning job fails or results in skipped entities. Users and groups are not provisioned to the target system. In the *Job Execution Details* screen, you see a maximum number of ten failed entities (although they might be more) and the content of each failed or skipped entity is hidden, that is: *content=<hidden content>*.

To further investigate the issue, you must enable tracing and logging.

1. Select the *Properties* tab of your source system and set the `ips.trace.failed.entity.content`, `ips.trace.skipped.entity` and `ips.trace.skipped.entity.content` properties to *true*.
2. Run again the provisioning job.
3. Navigate to *Provisioning Logs* > *Job Logs* and select the job that finished with error.
4. Choose the *Download* icon and select the respective log: *Download All Error Logs for This Job* or *Download All Skipped Entity Logs for This Job*.

Now, when you open the log file, you see all failed and skipped entities and their content (attributes). For example, if the failed entity is a group, you see its *displayName* and *members*.

How to Resolve 409 Error in SAP Analytics Cloud Target System

You want to know how to resolve a 409 error when using Identity Provisioning for provisioning users to SAP Analytics Cloud target system.

First, determine whether user creation or user update fails with HTTP 409. A creation attempt fails, if the job error log for the user contains the error: `Entity create failed with "Entity already exists"`, but the entity was not found by the unique attribute configured. An update attempt fails, if the job error log for the user contains the following path: `/api/v1/scim/Users/<SOME USER ID>`.

In both cases - the create and update failure scenarios, the underlying issue is that another user in SAP Analytics Cloud already uses the same email address. When this is the case, the error log includes a message like: `Email address is already used for <ID of the blocking user>`.

Before proceeding with the troubleshooting step, make sure to note the following:

- Whether the create or update action failed
- The ID of the blocking user (the user who owns the conflicting email)

Entity Deletion Issues [page 3121]
Additional Information [page 3130]
Handling Specific Attributes [page 3137]

1.12.15.4 Entity Deletion Issues

Learn how to troubleshoot the most frequent reasons for deletion of users or groups from a target system by the Identity Provisioning.

In the scenarios described below, the entity is already provisioned by the Identity Provisioning via a provisioning job from a source to a target system.

Since the topic is focused on occurrences of entity deletion, it only covers cases where deletion is expected. Deletion is not expected, when the provisioning job:

- has been run in a delta read mode;
- has failed entities for the source system;
- has an irreparable error for the source system;
- has irreparable errors for all target systems, which the job has to provision to.

It is important to clarify that even if an entity existed in the target system before its provisioning for the first time, it could still be deleted by the Identity Provisioning if the property `ips.delete.existedbefore.entities` is set to *true* in the target system. However, if the entity is created in the target system by provisioning in the first place, then the service is allowed to delete it , unless there is a threshold set for deletion of entities from the target or `“skipOperations”:[“delete”]` is present in the transformation of the target system.

Search among the most frequent causes for entity deletion by the Identity Provisioning and learn what should be checked to make sure that this is the situation you run into.

> → Recommendation
>
> For troubleshooting purposes, set the `ips.trace.deleted.entity` property to `true` on the source system. This enables you to download a ZIP archive containing details of all entities deleted during a given job. For more information, see List of Properties [page 80].

The Entity is Deleted From the Source System or Re-Created with a New ID

Access the audit logs for the source system and check for the deletion of the entity and eventually its re-creation with a new ID. If an entity previously provisioned to the target system was deleted in the source system, the deletion timestamp in the source system should be before the start time of the provisioning job that deleted the entity from the target.

Bellow you can find an exemplary audit log for deleted user from an Identity Authentication source system:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=delete
objectType=user
objectId=<the SCIM ID of the deleted user in IAS>
```

For more information, see Audit Logs.

Entity is not Returned from the API of the Source System When a Read or a Resync Job has Performed the Deletion

In the *Job Execution Details* screen, compare the *Read* statistics for the job, which deleted the entity, and the previous job for the same source-target systems pair. If you download all job logs, these statistics are displayed as value of the `numberRead` attribute. Check also if the next provisioning job for the same source-target systems re-created the entity in the target system.

In case of further investigation needed, please contact the corresponding API experts.

Entity Does not Meet the Filtering Criteria Defined in the Source System Anymore

Check if there is a filtering property set in the provisioning source system (`*.user.filter` or `*.group.filter`). Then look through the entity details in the source system itself and evaluate if it meets the defined filter.

You can also check the audit logs from the source system for entity changes that lead to not meeting the filtering criteria. The audit logs should span the period before the provisioning job that deleted the entity was run.

The entity may have temporarily failed to meet the defined filter while the deletion job was running in the target system. For exmaple, a user has became inactive in the source system and then active again after the job which deleted it from the target system has finished.

In the *Job Execution Details* screen, compare the *Read* statistics for the job, which deleted the user or the group, and the previous job for the same source-target systems pair. If you download all job logs, these statistics are displayed as value of the `numberRead` attribute. Check also if the next provisioning job for the same source-target systems has re-created the entity in the target system.

Bellow you can find an exemplary audit log for updated user that was deleted from Identity Authentication source system:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=update
objectType=user
objectId=<the SCIM ID of the deleted user in IAS>
payload: […]
//each changed attribute has its “oldValue” and "newValue" displayed
```

The Filter Set in the Source System was Changed and the Entity is no Longer Read by the Identity Provisioning

First, you can check if the filter property set in the source system has been changed. To do so, check the audit logs for any manual changes of the provisioning source system. The audit logs should span the period before the provisioning job that deleted the user.

After that, in the *Job Execution Details* screen, compare the *Read* statistics for the job, which deleted the entity, and the previous job for the same source-target systems pair. If you download all job logs, these statistics are displayed as the value of `numberRead` attribute. Check also if the next provisioning job for the same source-target systems re-created the entity in the target system.

For example, in case your SAP Cloud Identity Services tenant is running on SAP Cloud Identity Services Infrastructure, refer to Access Audit Logs (Audit Log Service in SAP BTP, Cloud Foundry) [page 2967] for more information. The procedure should have been applied before the Identity Provisioning sends audit logs to the Audit Log service.

Bellow you can find an exemplary audit log for updated filter of an Identity Authentication source system:

```
category=audit.configuration
crtAccount=<IPS tenant ID>
action=update
objectType=System
ObjectAttribute.system-old-details
ProvisioningSystem [id=<the ID of the provisioning system>, …, name=<the name of
the provisioning system>, …]
ObjectAttribute.performed-by-user
ObjectAttribute.system-new-details
```

You can see the difference between `system-old-details` and `system-new-details` for exact changes in the source system. The changes in the filter are part of the `“properties={…}”` sections of the old and the new details for the system.

The Entity Does not Meet an Existing Condition in the Read Transformation Anymore

Start by checking what is the condition in the read transformation of the source system. Then check the entity details in the source system itself and if it meets the condition.

You can also check on the *Job Execution Details* screen if the next provisioning job displays the entity as skipped in the statistics of the source system. You can download the job log for skipped entities and search for the entity in the downloaded file. For more information, see Download All Skipped Entity Logs for a Single Job [page 3011].

The entity may have temporarily failed to meet the defined condition while the deletion job was running in the target system. You can see audit logs from the source system for entity changes that lead to not applying to the condition. The audit logs should span the period before the provisioning job that deleted the entity was run.

For example, if a user is skipped, in the downloaded skipped entities job log you will see a similar content:

```
user:<user ID>,
system=<system name>,
skip reason=Entity condition [($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value)] is not fulfilled
//the skip reason could contain a different condition, but the sentence is
“Entity condition… is not fulfilled
```

In case you need to check audit logs, because the entity did not meet the condition only while one provisioning job was running, then for Identity Authentication source system, see Audit Logs. The procedure should have been applied, before Identity Provisioning sends audit logs to the Audit Log service.

Find bellow an exemplary content of an audit log for update of a user in an Identity Authentication source system that caused not meeting the defined condition:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=update
objectType=user
objectId=<the SCIM ID of the updated user in IAS>
payload: […]
//each changed attribute has its old and new values displayed (“oldValue” and
“newValue”)
```

The Entity Does not Meet an Existing Condition in the Target System Anymore

Start by checking what is the condition in the write transformation of the target system. Then check the entity details in the source system itself. Consider the transformation of the source system and how the values of the attributes are mapped to each `targetPath` there. Then, evaluate if the entity meets the condition set in the target system.

For example, if the user attribute for email in the source system is `email`, and there is a similar mapping in the transformation of the source system:

```
{
“sourcePath”: “$.email”,
“targetPath”: “$.emails[0].value”
}
```

And the condition in the target system using the email is the following:

```
"condition":"$.emails[0].value =~ /.*@domain.com/”,
//this condition checks if the email is on a particular domain
```

Then you should validate that the value of the user's attribute `email` in the source system ends with the specified domain in the condition of the target system.

You can also check if the next provisioning job for the same source-target systems show the user as skipped in the statistics of the target system. You can download the job log for skipped entities and search for the entity in the downloaded file. For more information, see Download All Skipped Entity Logs for a Single Job [page 3011].

The entity may have temporarily failed to meet the defined condition while the deletion job was running in the target system. You can see audit logs from the source system for entity changes that lead to not applying to the condition. The audit logs should span the period before the provisioning job that deleted the entity was run.

For example, if a user is skipped due to this reason, the downloaded skipped entities job log will include similar content:

```
user:<user ID>,
system=<system name>,
skip reason=Entity condition [($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value)] is not fulfilled
//the skip reason may contain a different condition, but the sentence is 'Entity
condition… is not fulfilled'
```

In case you need to check audit logs, because the entity did not meet the condition only while one provisioning job was running, then for Identity Authentication source system, see Audit Logs. The procedure should have been applied, before Identity Provisioning sends audit logs to the Audit Log service.

Find bellow an exemplary content of an audit log for update of a user in Identity Authentication source system that caused not meeting the set condition:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=update
objectType=user
objectId=<the SCIM ID of the updated user in IAS>
payload: […]
//each changed attribute has its old and new values displayed (“oldValue” and
“newValue”)
```

The Entity does not Meet a new Condition in the Source System

In that case, the entity is skipped after the Identity Provisioning reads it from the source system and it is deleted from the target.

You can check the transformation history and whether the condition in the read transformation was changed.

You can also check if the next provisioning job for the same source-target systems show the entity as skipped in the statistics of the target system. You can download the job log for skipped entities and search for the entity in the downloaded file. For more information, see Download All Skipped Entity Logs for a Single Job [page 3011].

The entity may have temporarily failed to meet the defined condition while the deletion job was running in the target system. You can see audit logs from the source system for entity changes that lead to not applying to the condition. The audit logs should span the period before the provisioning job that deleted the entity was run.

For example, if a user is skipped due to this reason, the downloaded skipped entities job log will include similar content:

```
user:<user ID>,
system=<system name>,
skip reason=Entity condition [($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value)] is not fulfilled
//the skip reason may contain a different condition, but the sentence is 'Entity
condition… is not fulfilled'
```

In case you need to check audit logs, because the entity did not meet the condition only while one provisioning job was running, then for Identity Authentication source system, see Audit Logs. The procedure should have been applied, before Identity Provisioning sends audit logs to the Audit Log service.

Find bellow an exemplary content of an audit log for a user update in Identity Authentication source system that caused not meeting the set condition:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=update
objectType=user
objectId=<the SCIM ID of the updated user in IAS>
payload: […]
//each changed attribute has its old and new values displayed (“oldValue” and
“newValue”)
```

The Entity does not Meet a new Condition set in the Target System

In that case, the entity is skipped during the provisioning to the target system and is deleted from it.

You can check the transformation history and whether the condition in the transformation of the target system was changed. After that, check the entity details in the source system itself. Consider the transformation of the source system and how the values of the entity attributes are mapped to each `“targetPath”` in the target system. Then, validate if the entity does not apply to the condition in the target system based on the mappings in the transformation of the source system and the values of the entity attributes in the source system.

For example, if the user attribute for email in the source system is `email`, and there is a mapping in the transformation of the source system like the following:

```
{
“sourcePath”: “$.email”,
“targetPath”: “$.emails[0].value”
}
```

If the condition in the target system using the `email` is the following:

```
“condition”: “$.emails[0].value =~ /.*@domain.com/”,
//checks if the email ends with the specified domain
```

Then validate that the value of the user attribute `email` in the source system ends with the specified domain in the condition of the target system.

You can also check if the next provisioning job for the same source-target systems show the entity as skipped in the statistics of the target system. You can download the job log for skipped entities and search for the entity in the downloaded file. For more information, see Download All Skipped Entity Logs for a Single Job [page 3011].

The entity may have temporarily failed to meet the defined condition while the deletion job was running in the target system. You can see audit logs from the source system for entity changes that lead to not applying to the condition. The audit logs should span the period before the provisioning job that deleted the entity was run.

If a user is skipped for not meeting the set condition in the target system, it will be seen in the downloaded skipped entities job log like:

```
user:<user ID>,
system=<system name>,
skip reason=Entity condition [($.emails EMPTY false) && ($.userName EMPTY false)
&& isValidEmail($.emails[0].value)] is not fulfilled
//the skip reason could contain a different condition, but the sentence is
'Entity condition… is not fulfilled'
```

In case you need to check audit logs, because the entity did not meet the condition only while one provisioning job was running, then for Identity Authentication source system, see Audit Logs. The procedure should have been applied, before the Identity Provisioning sends audit logs to the Audit Log service.

Find bellow an exemplary content of an audit log for user update in Identity Authentication source system that caused not meeting the set condition in the target system:

```
category=audit.data-change
crtAccount=<IAS tenant ID>
action=update
objectType=user
objectId=<the SCIM ID of the updated user in IAS>
payload: […]
// each changed attribute has its old and new values displayed (“oldValue” and
“newValue”)
```

Changed Mapping for `"entityIdTargetSystem"` or `"entityIdTargetSystem"` in the Transformation of the Source or Target System Without System Reset

This issue occurs most commonly, though not exclusively, while changing the version of the provisioning system, as this can lead to differences in the versions of the default transformations used. The symptom is mass entity update and mass entity deletion of the same entities in the target system.

If you think that this is probably your case, check the transformation history for changes in the mapping for one of the variables `"entityIdSourceSystem"` (part of the transformation of the source system) or `"entityIdTargetSystem"` (part of the transformation of the target system). Then, check in the audit logs whether a reset was performed for the provisioning system, in which one of the above mentioned variables was changed. The audit logs should span the period before the provisioning job that deleted the entity was run.

For example, in case your SAP Cloud Identity Services tenant is running on SAP Cloud Identity Services Infrastructure, refer to Access Audit Logs (Audit Log Service in SAP BTP, Cloud Foundry) [page 2967] for more information. The procedure should have been applied before the Identity Provisioning sends audit logs to the Audit Log service.

Bellow you can find an exemplary audit log for system reset of Identity Authentication source system:

```
category=audit.configuration
crtAccount=<IPS tenant ID>
action=update
objectType=System
ObjectAttribute.event-type=SYSTEM_RESET
```

```
ObjectAttribute.performed-by-user
ObjectAttribute.system-id=<the ID of the provisioning system>
```

If the provisioning system was reset, this has not caused the entity deletion.

If the provisioning system was not reset but one of the above mentioned variables was changed, that caused the entities deletion.

Removed `"delete"` Operation from skipOperations Expression or the skipOperations Expression Itself from the Transformation of the Target System

All entities, which were due to be deleted from the target system while skip of `"delete"` operation was present, were reported in previous jobs as skipped. As a result from removing the `"delete"` operation or the entire skipOperations expression, they can now be deleted from the target system by the Identity Provisioning.

In that case, you can compare the skipped statistics of the job, which deleted the entities, and the previous job for the same source-target systems. If you download all job logs, these statistics are shown in the value of `“numberSkipped”` attribute. The skipped statistics should be checked for the target system, where the entity was deleted from. You can also download the job log for skipped entities of both jobs (the one that deleted the entity from the target system and the previous one) and find the entity in the downloaded file of the older job. For more information, see Download All Skipped Entity Logs for a Single Job [page 3011].

You can also check the transformation history and whether the skipOperations expression contained `“delete”` before the provisioning job that deleted the entity from the target system was triggered.

If a user was skipped due to this reason, it will be seen in the downloaded skipped entities job log like:

```
user:<user ID>,
system=<target system name>,
skip reason=Operation [delete] is skipped in target transformation,
```

Single or Mass Entity Deletion Because the Entities Were not Deleted Earlier

Single or, more likely, mass entity deletion may occur if any of the cases described above happened during an earlier provisioning job, where an error prevented that job from deleting the entities from the target system.

Some of these errors could be:

- failed entities for the source system
- irreparable issue during provisioning, like a connection issue, which stopped the job before it reached the point of deletion of the entities
- delete operation failure
- other

As a result, the entities are queued for deletion by the next provisioning job, which will try again to delete them once the above mentioned issues are resolved.

You can start the investigation by checking the job logs, statistics, and job error logs of the provisioning jobs prior the one that deleted the entities. For more information, see Manage Provisioning Job Logs [page 3010].

Proof that you have run into some of the listed situations could include:

- If there were failed entities for the source system in the previous jobs, and then there were no failed entities for the source system in the job, which deleted the users from the target system.
- If there were some irreparable errors for the source system or for the target system (where the entities were deleted from) in the previous jobs, and then there were no such irreparable errors in the job, which deleted the entities from the target system. Irreparable errors are connection issues, like connection reset, some timeout exception, rate limits (response code 429 from the API of a provisioning system), and others.
- If there were failed entities for the target system in the previous jobs, the failures were for the entities that got deleted later from the target system, and the error job logs show failed delete operation.
  For example, if a user deletion failed, it will be displayed in the downloaded error job log as follows:

  ```
  user:<user ID>,
  system=<system name>,
  time=<time error happened>
  error=<the error details>
  content=null
  ```

As a last step, you can analyze the job logs of the previous jobs for some issues or patterns, which are not observed in the job, which deleted the entities from the target system.

How to Prevent Incorrect Entity Deletion in These Cases

By following some of the hints bellow, you can avoid unintended deletion of entities from your target systems:

- Add the standard property `ips.delete.threshold.users` (or `ips.delete.threshold.groups` for groups) to your target system configuration before running a provisioning. For more information, see the blog Thresholds Prevent Unintended Deletion of Users when Provisioning with SAP Cloud Identity Services.
- Migrate your Identity Provisioning tenant from SAP BTP Neo environment to SAP Cloud Identity Infrastructure, where you will be able to use more features (like the validate job, seeing skipped entities for a job execution, and many others). For more information, see the blog Go for your quick win! Migrate Identity Provisioning tenants to SAP Cloud Identity infrastructure.
- Always execute a validate job first, after doing a change in the transformation or properties of a provisioning system. For more information, see the blog Simulate it until you make it! Try out the Identity Provisioning job that tests your configuration.
- Follow all steps of the process for updating the connector version, decribed in Update Connector Version [page 2424].

1.12.15.5 Additional Information

Extended Explanation of the *.user.roles.overwrite Properties

Job Logs

You have a target or a proxy system of one of the following types:

- SAP S/4HANA Cloud Public Edition
- SAP Marketing Cloud
- SAP Market Communication for Utilities
- SAP BTP ABAP Environment
- SAP SAP Integrated Business Planning Cloud

You want to know the correct way to preserve or overwrite user roles on your target or proxy system. Thus, you need to know how to use the relevant **.user.roles.overwrite* properties, and whether or not to make additional changes in your transformations.

Scenarios

1. You want to keep existing user assignments (roles) on the target system
   Meaning:
   During the provisioning, you want to keep existing roles assigned to users on the target system, and add new assignments, if any . That means:
   - Keeping user assignments (roles) that exist only on the target system
   - Keeping user assignments (roles) that exist on both the source and the target system
   - Assigning new roles, which are read from the source system (if any), to users on the target system

   > **Example**
   >
   > Role A and B exist on the source system, and roles A, B, and C exist on the target system. Let's say a user is assigned to role (group) A in the source system, and the same user is assigned to roles B and C in the target system. You want role A to be added, and roles B and C to be preserved as assignments for this user in the target system. That is, after the provisioning, this user has to have roles A, B and C assigned to it on the target/proxy system.

   What do you need to do?

1. Set the relevant **.user.roles.overwrite* property to false.
2. Make sure you have the following mapping in the `"user"` object of your target/proxy write transformation:

   Sample Code

   ```
   {
       "sourcePath": "$.groups[*].value",
       "preserveArrayWithSingleElement": true,
       "targetPath": "$.user.role[?(@.roleName)]",
       "optional": true
   },
   ```

3. Remove the whole `"group"` object from your target transformation. That is:

   Sample Code

   ```
   "group": {
     "mappings": [
       {
           "sourcePath": "$.displayName",
           "targetVariable": "entityIdTargetSystem",
           "scope": "createEntity"
       },
       {
           "sourcePath": "$.displayName",
           "targetPath": "$.displayName"
       },
       {
           "sourcePath": "$.displayName",
           "targetPath": "$.ID"
       },
       {
           "sourcePath": "$.members[*].value",
           "preserveArrayWithSingleElement": true,
           "optional": true,
           "targetPath": "$.members[?(@.value)]",
           "functions": [
              {
                  "function": "resolveEntityIds"
              }
           ]
       }
     ]
   }
   ```

   Note

   For proxy systems, the `"group"` object looks a bit different.

2. You want to overwrite existing user assignments (roles) on the target system

   Meaning:

   During the provisioning, you want to unassign roles assigned to users on the target system, and assign only roles read from the source system. That means:

   - Unassigning all user assignments (roles) that are assigned to the user on the target system (unassigning roles which exist on both source and target system, as well as roles existing only on the target system)
   - Assigning user assignments (roles) read from the source system to the user on the target system

Example

Role A and B exist on the source system, and roles A, B, and C exist on the target system. Let's say a user is assigned to role (group) A in the source system, and the same user is assigned to roles B and C in the target system. You want role A to be added, and roles B and C to be unassigned from this user in the target system. That is, after the provisioning, this user has to have only role A assigned to it on the target/proxy system.

What do you need to do?

1. Set the relevant **.user.roles.overwrite* property to true.
2. Make sure you have the following mapping in the `"user"` object of your target/proxy write transformation:

   ### Sample Code

   ```
   {
       "sourcePath": "$.groups[*].value",
       "preserveArrayWithSingleElement": true,
       "targetPath": "$.user.role[?(@.roleName)]",
       "optional": true
   },
   ```

3. Remove the whole `"group"` object from your target transformation. That is:

   ### Sample Code

   ```
   "group": {
     "mappings": [
       {
           "sourcePath": "$.displayName",
           "targetVariable": "entityIdTargetSystem",
           "scope": "createEntity"
     },
     {
           "sourcePath": "$.displayName",
           "targetPath": "$.displayName"
     },
     {
           "sourcePath": "$.displayName",
           "targetPath": "$.ID"
     },
     {
           "sourcePath": "$.members[*].value",
           "preserveArrayWithSingleElement": true,
           "optional": true,
           "targetPath": "$.members[?(@.value)]",
           "functions": [
              {
                  "function": "resolveEntityIds"
              }
           ]
       }
     ]
   ```

   ### Note

   For proxy systems, the `"group"` object looks a bit different.

3. You want to update groups, read from the source system, and their assignments (users) on the target system

Meaning:
During the provisioning, you want to update groups, read from the source system, and their assignments on the target system. That means:

- Updating groups, read from the source system, and their assignments (users) on the target system
- Groups that are not read from the source system (existing only on the target system) and their assignments will not be updated on the target system

> ### Example
>
> Role A exists on the source system, and roles A and B exist on the target system. Let's say, on the source system role A has assigned member user X, and on the target system it has no members assigned. Role B has assigned member user X on the target system. You want user X to be added as a member to role A on the target, and don't want to update role B. That is, after the provisioning, role A will have member X assigned, and role B will not be updated, thus it will still have member user X assigned.

What do you need to do?

1. Set the relevant **.user.roles.overwrite* property to false.
2. Delete the following mapping in the `"user"` object from your target/proxy write transformation:

   > ### Sample Code
   >
   ```
   {
       "sourcePath": "$.groups[*].value",
       "preserveArrayWithSingleElement": true,
       "targetPath": "$.user.role[?(@.roleName)]",
       "optional": true
   },
   ```

3. Add the following `"group"` object to your target transformation.

   > ### Sample Code
   >
   ```
   "group": {
     "mappings": [
       {
          "sourcePath": "$.displayName",
          "targetVariable": "entityIdTargetSystem",
          "scope": "createEntity"
       },
       {
          "sourcePath": "$.displayName",
          "targetPath": "$.displayName"
       },
       {
          "sourcePath": "$.displayName",
          "targetPath": "$.ID"
       },
       {
          "sourcePath": "$.members[*].value",
          "preserveArrayWithSingleElement": true,
          "optional": true,
          "targetPath": "$.members[?(@.value)]",
          "functions": [
             {
                 "function": "resolveEntityIds"
             }
          ]
       }
   ```

```
]
```

> **Note**
>
> For proxy systems, look at the default write transformation and copy the `"group"` object from there.

> **Caution**
>
> When provisioning user assignments through the `"user"` object, make sure that the existing target roles have the exact same names as the relevant source groups! Otherwise, the default mapping won't work.
>
> Still, if you need to map source groups whose names are different than the relevant target roles,configure the relevant mapping the following way for all affected group-role pairs:
>
> **Sample Code**

```
...
   {
        "condition": "$.groups[*].value contains
'<sourceGroupName1>'",
        "constant": "<targetGroupName1>",
        "targetPath": "$.user.role[0].roleName"
   },
   {
        "condition": "$.groups[*].value contains
'<sourceGroupName2>'",
        "constant": "<targetGroupName2>",
        "targetPath": "$.user.role[1].roleName"
   }
...
```

Negative Condition Statements in Transformations (Examples)

Problem

You want to use negations (**"not"** conditions) in the transformations of your provisioning systems but you struggle with finding the right way to do it.

Take a look at the examples below - they represent the most frequently used negations, according or regardless of the system type.

Examples

Negative Condition	Meaning
`"condition": "$.userName != 'John Smith'"`	"If the user name is not John Smith, then..."
`"condition": "%s4hana.cloud.hr.switch.active% != null && %s4hana.cloud.hr.switch.active% == true",`	"If the `s4hana.cloud.hr.switch.active` property is set, and its value is *TRUE* (which means HR integration is enabled), then ..."
`"condition": "('${nestedPathVariable}' != '')",`	"If the transformation variable `<nestedPathVariable>` does not have an empty value, then ..."
`"condition": "('%ldap.attribute.user.id%' != '%ldap.attribute.dn%')",`	"If the system property `ldap.attribute.user.id` does not have the same value as the system property `ldap.attribute.dn`, then ..."
`"condition": "$.emails[?(@.type != 'work')].value != []",`	"If the values of emails of type different than `'work'` are different than empty array, then ..."

SAP S/4HANA Based Systems: Business Role Description

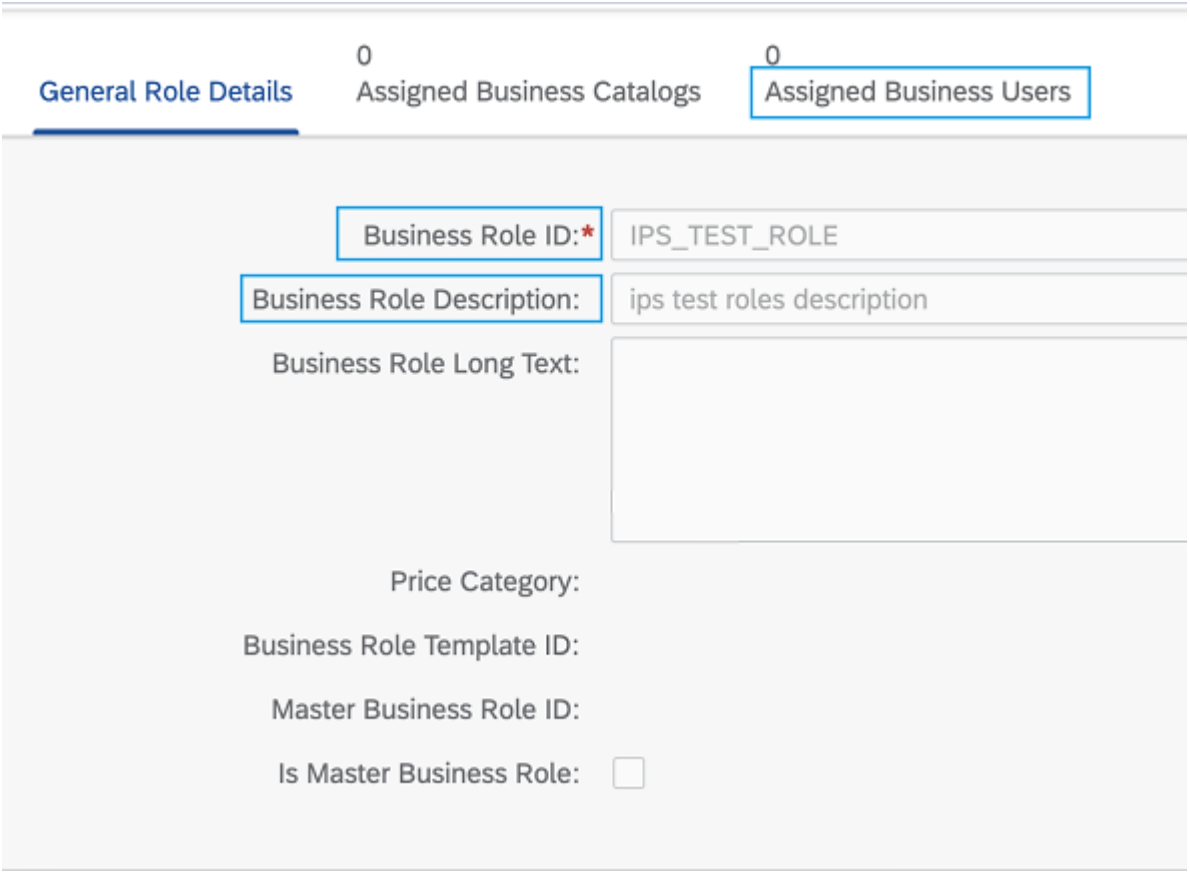
Scenario

You have a source or a proxy system of the following types:

- SAP S/4HANA Cloud Public Edition
- SAP Marketing Cloud
- SAP BTP, ABAP Environment
- SAP Integrated Business Planning Cloud

By default, Identity Provisioning reads *group ID* (= Business Role ID) and *members* (= Assigned Business Users).

Now, the service can also read *group descriptions* (= Business Role Description). To learn how to do this, see the *Solution* section below.



All this group information can be provisioned to a target system, or read by a consuming application (like SAP Identity Management) in proxy scenarios.

Solution

To make Identity Provisioning read the descriptions of groups (roles), you need to add the following mapping in the `"group"` resource of your source/proxy system:

Sample Code

```
...
   {
      "sourcePath": "$.Description",
      "optional": true,
      "targetPath": "$.description"
  },
...
```

Therefore, if you place it for example after the *ID* mapping, your `"group"` resource should look like this:

Sample Code

```
"group": {
      "mappings": [
         {
             "sourcePath": "$.ID",
             "targetPath": "$.displayName",
             "targetVariable": "entityIdSourceSystem"
         },
```

```
          {
              "sourcePath": "$.Description",
              "optional": true,
              "targetPath": "$.description"
          },
          {
              "constant": "urn:ietf:params:scim:schemas:core:2.0:Group",
              "targetPath": "$.schemas[0]"
        },
...
```

1.12.15.6 Handling Specific Attributes

Manage specific user and group attributes during the provisioning of entities to different systems.

SAP HANA Database Username and Email

In SAP HANA Cloud, SAP HANA Database, users have an immutable HANA database username and are not expected to have an associated email. This affects provisioning scenarios, particularly with Identity Authentication, and requires changes in the transformations.

When users are provisioned from Identity Authentication to SAP HANA Cloud, SAP HANA Database, the **userID** attribute (P-user in Identity Authentication) is mapped to the **userId** attribute (HANA database username in SAP HANA Cloud, SAP HANA Database) and provisioned accordingly. The HANA database username should not to be confused with UserName. Given that the User ID in Identity Authentication is unique only within a specific tenant, consider the following cases when your organization uses multiple tenants:

Use Case 1 - Change tenants

- You have two SAP Cloud Identity Services tenants (tenant 1 and tenant 2).
- You have provisioned the users from tenant 1 to SAP HANA Cloud, SAP HANA Database.
- Now you want to change tenant 1 with tenant 2 and start provisioning the users from tenant 2 to SAP HANA Cloud, SAP HANA Database.

In this case, one and the same user in tenant 1 and tenant 2 might have different P user values. For example: John Smith (P000001) exists in tenant 1 and John Smith (P000002) exists in tenant 2. The Identity Provisioning won't be able to transfer the value from tenant 2, because the HANA database username is immutable.

We suggest handling this as follows:

1. Delete the affected users in the target SAP HANA Cloud, SAP HANA Database system. That is, John Smith (P000001).
2. Run a provisioning job from the Identity Authentication source system in your tenant 2.
   As a result, the user John Smith will be provisioned with his P000002 P user.

Use Case 2 - Use more than one tenant

- You have two SAP Cloud Identity Services tenants (tenant 1 and tenant 2) in different regions, for example, and you want to use both.

In this case, different users in tenant 1 and tenant 2 might have the same P user value. For example, John Smith (P000001) in tenant 1 (Europe) and Julie Armstrong (P000001) in tenant 2 (Asia).

We suggest handling this as follows:

1. Modify the read transformation in the Identity Authentication source system of your tenant 1 by adding, for example, a prefix or a suffix to the P user value.

Code Syntax

```
{
  "sourcePath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "targetPath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "functions": [
    {
      "function": "concatString",
      "prefix": "Europe_"
    }
  ]
}
```

Code Syntax

```
{
  "sourcePath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "targetPath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "functions": [
    {
      "function": "concatString",
      "suffix": "_Europe"
    }
  ]
}
```

2. Modify the read transformation in the Identity Authentication source system of your tenant 2 by adding, for example, a prefix or a suffix to the P user value.

Code Syntax

```
{
  "sourcePath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "targetPath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "functions": [
```

Code Syntax

```
{
  "sourcePath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "targetPath": "$
['urn:ietf:params:scim:schemas:ext
ension:sap:2.0:User']['userId']",
  "functions": [
```

```
    {
      "function": "concatString",
      "prefix": "Asia_",
    }
  ]
}
```

```
    {
      "function": "concatString",
      "suffix": "_Asia"
    }
  ]
}
```

3. Run provisioning jobs from both Identity Authentication source systems in tenant 1 and tenant 2.
   As a result, you will distinguish the different users with the same P user value by adding a prefix.

Use Case 3 - Email of SAP HANA Database User

- You want to provision SAP HANA Database users to Identity Authentication. The users don't have email addresses, as this is neither expected nor needed. However, email is a required user attribute in Identity Authentication.

We suggest handling this as follows:

1. Modify the read transformation in the SAP HANA Cloud, SAP HANA Database source system to construct a fictitious email address by appending the username with a suffix that includes the "@" sign and a domain.

   Code Syntax

   ```
   {
     "sourcePath": "$.userName",
     "targetPath": "$.emails[0].value",
     "functions": [
       {
         "function": "concatString",
         "suffix": "@test.test"
       }
     ]
   }
   ```

2. Run a provisioning job from the source system.
   As a result, you will meet the following condition of the target Identity Authentication: `"condition": "($.emails EMPTY false) && ($.userName EMPTY false) && isValidEmail($.emails[0].value)"`, and the job will not fail due to a missing required attribute.

1.13 Submitting Improvement Requests

You can submit your improvement request for Identity Authentication. It's a single central place for all product improvement request related activities. You can browse improvement requests, submit improvement requests, comment, vote, receive updates, and browse who has voted.

Context

You can also browse improvement requests, comment, vote, receive updates, and browse who has voted.

> **Note**
>
> Before you submit your improvement, check if a similar improvement hasn't already been submitted requested. If yes, vote for it, instead of submitting a new one.

Procedure

1. Access the SAP Continuous Influence site from the following link: https://cis.influence.sap.com/
2. Sign in with your email if required.
3. Choose *SAP Business Technology Platform - Foundation* > *Security Services>Add an improvement request* .
4. Enter the details for the improvement request that you want to submit.

Field	Notes
Choose a session for this Improvement Request	SAP Business Technology Platform. It's already prefilled from the drop-down list.
Your Improvement Request	Enter a one-sentence summary here clearly stating your request and area of improvement.
Choose a category for this Improvement Request	*Security Services*. It's already prefilled from the drop-down list.
Problem description	Provide details about your idea.
Solution proposal	Propose a solution.
Expected benefit	Explain what is the benefit from this improvement.

   You can also provide links and attachments.

5. Choose the *ADD IMPROVEMENT REQUEST* button when you're ready.

1.14 Getting Support

This document is to help users, administrators, and developers deal with issues from SAP Cloud Identity Services.

SAP Support Portal

You can report an incident on SAP Support Portal Home with the following components:

- `BC-IAM-IDS` - for issues related to authentication and user and group management
- `BC-IAM-IPS` - for issues related to user and group provisioning
- `BC-IAM-OID` - for issues related to OpenID Connect tokens

> **Note**
>
> Please include in the incident the following information:
>
> - Your tenant ID from `https://tenant ID>.accounts.ondemand.com/admin` or `https://<tenant ID>.accounts.cloud.sap/admin`
> - Your email address
> - The error message you see
> - Attachments of screenshot that show the reproduced error, including the exact timestamp
> - If you solved your issue, a description of the steps you took
> - List of Knowledge Base Articles (KBAs) and SAP Notes, you have used to solve the issue
> - (if relevant) Attachments of SAML traces as per KBA: 2461862 - Collecting SAML traces with Chrome or Firefox
>
> See also: 2654164 (What to consider before opening a Support Incident for SAP BTP issue).

SAP Community Network

You can start a discussion in the Security Community.

1.15 Updates and Notifications

SAP Cloud Identity Services production updates follow a regular biweekly release schedule and are generally delivered mid-week. For more information about the newly introduced features, see the What's New for Cloud Identity Services [page 26] page.

Subscription for Notifications

To get notifications about new releases and related updates, subscribe to the *What's New* section of Cloud Identity Services.

Reasons for Updates

- **Bi-weekly updates** (standard)
  Standard updates are delivered on a bi-weekly basis. You can find the planned schedule for upcoming releases in the SAP Note 3409744 (Release Schedule for SAP Cloud Identity Services (SAP BTP)).
- **Immediate updates**
  Immediate updates are provided when fixes are required for issues that affect productive application operations or when urgent security fixes are necessary.

> **Note**
>
> No service interruption is expected as a result of the updates.

Service Availability

You can monitor the availability of Identity Authentication in Cloud Availability Center CAC/SAP4Me. For that you can see a T-installation for Identity Services in the support tools. The Identity Authentication tenants of a customer are assigned to this T-installation. Based on these T-installations you can request outage notifications, and see potential Root Cause Analysis (RCA) information.

Important Disclaimers and Legal Information

Hyperlinks

Some links are classified by an icon and/or a mouseover text. These links provide additional information.
About the icons:

- Links with the icon : You are entering a Web site that is not hosted by SAP. By using such links, you agree (unless expressly stated otherwise in your agreements with SAP) to this:
  - The content of the linked-to site is not SAP documentation. You may not infer any product claims against SAP based on this information.
  - SAP does not agree or disagree with the content on the linked-to site, nor does SAP warrant the availability and correctness. SAP shall not be liable for any damages caused by the use of such content unless damages have been caused by SAP's gross negligence or willful misconduct.
- Links with the icon : You are leaving the documentation for that particular SAP product or service and are entering an SAP-hosted Web site. By using such links, you agree that (unless expressly stated otherwise in your agreements with SAP) you may not infer any product claims against SAP based on this information.

Videos Hosted on External Platforms

Some videos may point to third-party video hosting platforms. SAP cannot guarantee the future availability of videos stored on these platforms. Furthermore, any advertisements or other content hosted on these platforms (for example, suggested videos or by navigating to other videos hosted on the same site), are not within the control or responsibility of SAP.

Beta and Other Experimental Features

Experimental features are not part of the officially delivered scope that SAP guarantees for future releases. This means that experimental features may be changed by SAP at any time for any reason without notice. Experimental features are not for productive use. You may not demonstrate, test, examine, evaluate or otherwise use the experimental features in a live operating environment or with data that has not been sufficiently backed up.
The purpose of experimental features is to get feedback early on, allowing customers and partners to influence the future product accordingly. By providing your feedback (e.g. in the SAP Community), you accept that intellectual property rights of the contributions or derivative works shall remain the exclusive property of SAP.

Example Code

Any software coding and/or code snippets are examples. They are not for productive use. The example code is only intended to better explain and visualize the syntax and phrasing rules. SAP does not warrant the correctness and completeness of the example code. SAP shall not be liable for errors or damages caused by the use of example code unless damages have been caused by SAP's gross negligence or willful misconduct.

Bias-Free Language

SAP supports a culture of diversity and inclusion. Whenever possible, we use unbiased language in our documentation to refer to people of all cultures, ethnicities, genders, and abilities.
